## **Canadian Technical Report of Fisheries and Aquatic Sciences**

Technical reports contain scientific and technical information that contributes to existing knowledge but which is not normally appropriate for primary literature. Technical reports are directed primarily toward a worldwide audience and have an international distribution. No restriction is placed on subject matter and the series reflects the broad interests and policies of the Department of Fisheries and Oceans, namely, fisheries and aquatic sciences.

Technical reports may be cited as full publications. The correct citation appears above the abstract of each report. Each report is abstracted in *Aquatic Sciences and Fisheries Abstracts* and indexed in the Department's annual index to scientific and technical publications.

Numbers 1-456 in this series were issued as Technical Reports of the Fisheries Research Board of Canada. Numbers 457-714 were issued as Department of the Environment, Fisheries and Marine Service, Research and Development Directorate Technical Reports. Numbers 715-924 were issued as Department of Fisheries and the Environment, Fisheries and Marine Service Technical Reports. The current series name was changed with report number 925.

Technical reports are produced regionally but are numbered nationally. Requests for individual reports will be filled by the establishment listed on the front cover and title page. Out-of-stock reports will be supplied for a fee by commercial agents.

## **Rapport technique canadien des sciences halieutiques et aquatiques**

Les rapports techniques contiennent des renseignements scientifiques et techniques qui constituent une contribution aux connaissances actuelles, mais qui ne sont pas normalement appropriés pour la publication dans un journal scientifique. Les rapports techniques sont destinés essentiellement à un public international et ils sont distribués à cet échelon. Il n'y a aucune restriction quant au sujet; de fait, la série reflète la vaste gamme des intérêts et des politiques du ministère des Pêches et des Océans, c'est-à-dire les sciences halieutiques et aquatiques.

Les rapports techniques peuvent être cités comme des publications complètes. Le titre exact paraît au-dessus du résumé de chaque rapport. Les rapports techniques sont résumés dans la revue *Résumés des sciences aquatiques et halieutiques*, et ils sont classés dans l'index annuel des publications scientifiques et techniques du Ministère.

Les numéros 1 à 456 de cette série ont été publiés à titre de rapports techniques de l'Office des recherches sur les pêcheries du Canada. Les numéros 457 à 714 sont parus à titre de rapports techniques de la Direction générale de la recherche et du développement, Service des pêches et de la mer, ministère de l'Environnement. Les numéros 715 à 924 ont été publiés à titre de rapports techniques du Service des pêches et de la mer, ministère des Pêches et de l'Environnement. Le nom actuel de la série a été établi lors de la parution du numéro 925.

Les rapports techniques sont produits à l'échelon régional, mais numérotés à l'échelon national. Les demandes de rapports seront satisfaites par l'établissement auteur dont le nom figure sur la couverture et la page du titre. Les rapports épuisés seront fournis contre rétribution par des agents commerciaux.

**ABSTRACT**

Lochead, J.K., and Yamanaka, K.L. 2007. Summary report for the inshore rockfish (*Sebastes spp.*) longline survey conducted in Statistical Areas 14 to 20, 28 and 29, from August 11 to September 6, 2005. Can. Tech. Rep. Fish. Aquat. Sci. 2690: viii + 53 p.

Since 2003, a longline survey has been conducted in portions of the inside waters between Vancouver Island and the mainland, referred to as the Strait of Georgia Management region (statistical areas 12 to 20, 28 and 29), to provide catch rate indices and associated biological data for the assessment of inshore rockfish (*Sebastes ruberrimus*, *S. maliger*, *S. caurinus*, *S. nebulosus* and *S. nigrocinctus*). Statistical areas (SA) 12 and 13 were surveyed in the first two years and in 2005 the survey was moved south to SA 14 through 20, 28 and 29. Similar fishing and sampling methods were used for all three surveys (Lochead and Yamanaka, 2004, 2006). This report summarizes catch and biological sample data from the 2005 survey, and presents spatial analyses of catch rate by statistical area based on data from the 2003, 2004 and 2005 surveys. Quillback rockfish catch rates are low (<1 kg/skate) in SA 15 through 20, 28 and 29 and higher in SA 12 to 14. Catch rates are highest in SA 12 for quillback rockfish. Yelloweye rockfish catch rates are low (<1 kg/skate) in SA 18 through 20, 28 and 29 and higher in SA 12 through 17. Catch rates are highest in SA 15 for yelloweye rockfish.

Habitat is known to be an important influence on the distribution of rockfishes with the variation in substrate type and slope contributing to catch rate variability among sets. A spatial analysis of species catch rate and substrate class, determined by bathymetric position index (BPI) values, was conducted to quantify the catch rate-substrate relationship. Results indicate that quillback rockfish and yelloweye rockfish catch rates varied significantly with BPI classes. BPI analyses may be useful in future survey design whereby specific slope classes or habitats are targeted to reduce catch rate variability.

## RÉSUMÉ

Lochead, J.K., and Yamanaka, K.L. 2007. Summary report for the inshore rockfish (*Sebastes spp.*) longline survey conducted in Statistical Areas 14 to 20, 28 and 29, from August 11 to September 6, 2005. Can. Tech. Rep. Fish. Aquat. Sci. 2690: viii + 53 p.

Depuis 2003, un relevé à la palangre est effectué dans les eaux intérieures situées entre l'île de Vancouver et la terre ferme, désignées comme la région de gestion du détroit de Georgia (zones statistiques 12 à 20, et 28 et 29), en vue d'obtenir des indices de taux de capture et des données biologiques connexes pour l'évaluation des sébastes côtiers (*Sebastes ruberrimus*, *S. maliger*, *S. caurinus*, *S. nebulosus* et *S. nigrocinctus*). Les zones statistiques 12 et 13 ont été recensées en 2003 et 2004. En 2005, le relevé a été effectué plus au sud, dans les zones 14 à 20 et les zones 28 et 29. Les mêmes méthodes de pêche et d'échantillonnage ont été utilisées pour les trois relevés (Lochead et Yamanaka, 2004; 2006). Sont ici résumées les données sur les prises et les données biologiques recueillies dans le cadre du relevé de 2005 et présentées des analyses spatiales des taux de capture selon la zone statistique fondées sur les données recueillies en 2003, 2004 et 2005. Les taux de capture du sébaste à dos épineux dans les zones 15 à 20, ainsi que dans les zones 28 et 29, sont faibles (<1 kg/jeu de lignes); ils sont plus élevés dans les zones 12 à 14, en particulier dans la zone 12. Les taux de capture du sébaste aux yeux jaunes sont faibles dans les zones 18 à 20, ainsi que dans les zones 28 et 29 (< 1 kg/jeu de lignes); ils sont plus élevés dans les zones 12 à 17, en particulier dans la zone 15.

L'habitat est reconnu comme agissant fortement sur la distribution des sébastes. La variation dans le type de substrat et la pente contribue à la variabilité des taux de capture entre les mouillages. L'analyse spatiale des taux de capture de chaque espèce selon le type de substrat, établi d'après les indices de position bathymétrique (IPB), a servi à quantifier la relation entre le taux de capture et le type de substrat. Les résultats de cette analyse révèlent que les taux de capture du sébaste à dos épineux et du sébaste aux yeux jaunes varient significativement selon les classes d'IPB. L'analyse des IPB pourrait se révéler utile dans la conception des plans d'échantillonnage futurs du fait qu'elle permettrait de cibler des classes de pente ou des parcelles d'habitat précises afin de réduire la variabilité des taux de capture.

## **1.0 INTRODUCTION**

To provide a relative index of abundance for the assessment of inshore rockfish stocks, a longline survey has been conducted in the Strait of Georgia Management region annually since 2003. In 2003, a pilot survey was conducted in Statistical Areas (SA) 12 and 13 (Lochead and Yamanaka, 2004). In 2004, SA 12 and 13 were re-surveyed and the inter-annual variability in catch rates quantified (Lochead and Yamanaka, 2006). In 2005, SA 14 – 20, 28 and 29 were surveyed to expand the spatial coverage of relative abundance indices and biological data to the entire Strait of Georgia Management region.

## **2.0 METHODS**

The 2005 survey methodology was identical to that used in 2003 and 2004. A general description of the survey methods is presented below; for a more detailed description see Lochead and Yamanaka (2004).

### **2.1 Survey Design**

The survey employed a depth-stratified, random design to select 2 km by 2 km survey blocks to fish (Lochead and Yamanaka 2004). All waters in SA 14 – 20, 28 and 29 between the depths of 41 to 100 metres were stratified into shallow (41 – 70m) and deep (71 – 100m) depth strata using Canadian Hydrographic Service (CHS) charts. To ensure rockfish habitat was targeted, CHS charts were used to eliminate blocks that were located on flat, mud or sandy bottom. A total of 1114 blocks remained and these blocks were spatially stratified by statistical area then eight percent of the blocks within each statistical area were randomly selected to fish (ESRI® ArcMap™ 9.0), totalling 89 sampling blocks for the survey. During the survey, if blocks were unfishable due to the lack of suitable habitat within the depth strata, these were removed from the survey grid and a new survey block was randomly selected from adjacent blocks using GIS software (ESRI® ArcMap™ 9.0) and fished.

### **2.2 Survey Vessel**

Since its inception, the survey has been conducted on board the fisheries research vessel CCGS *Neocaligus*. In 2005, the vessel was skippered by Captain Alan Young and Captain Bob Barker. The ship's compliment consisted of a bosun, engineer, deck hand/cook and 3 scientific staff.

### **2.3 Fishing Gear and Operations**

Snap-type longline gear using in previous years was also used in 2005. Each longline set or 'string' consisted of two skates of groundline with 225 circle hooks (13/0) spaced 3.7 m (12 ft) apart, and perlon gangions measuring 0.38 m (1.2 ft) were crimped at both ends and attached to the circle hook with a swivel (Lochead and Yamanaka,

2004). Hooks were baited with thawed Argentinean squid, approximately 15 cm long, and cut into fifths.

For each set, the start and end positions and depths were recorded when the first and last anchors were set over the stern, from the vessel's global positioning system (GPS) and depth sounder, respectively (Lohead and Yamanaka, 2004). Minimum, maximum and modal depths were also recorded. Modal set depth was used to assign each set to either the shallow or deep depth stratum.

In all years, survey blocks were fished during daylight hours and soak time, described as the time elapsed between the last anchor over the stern and the first anchor retrieved on board, was standardized to 2 hours (Lohead and Yamanaka, 2004).

## **2.4 Data Collection**

In 2005, for the first time, all hook by hook and biological data were recorded directly into an Allegro CE™ hand-held field computer (Juniper Systems Incorporated). The yield on each hook was recorded on deck as the gear was retrieved (Lohead and Yamanaka, 2004). The catch was identified to species and recorded with individual hook numbers. Fish and invertebrates were considered 'catch' if they broke the surface of the water during gear retrieval. Partial fish returning on hooks, usually heads whose bodies were predated, and fish drop-offs at the side of the vessel were also recorded into the Allegro CE™. Average whole fish weights for these species were estimated from previous surveys and added to the total catch weight. During gear retrieval, the catch was sorted by species into baskets and set aside for sampling. After retrieving the gear, the total catch weight, by species, was recorded and biological sampling began.

### ***2.4.1 Biological sampling***

Biological sampling consisted of measuring weight (W) in grams (g), length (L) in millimetres (mm) or centimetres (cm), and visually determining the sex (S) and maturity state (M) of the gonads (Westrheim, 1975). Both sagittal otoliths (O) were extracted from rockfish and fin rays (F) were removed from lingcod (*Ophiodon elongatus*) for subsequent age determination. L/W/S/M/O samples were collected from all rockfish, L/W/S/M/F samples were collected from lingcod, and L/S or L samples were collected from all other fish species. A matchstick-size piece of caudal fin was removed from rockfish and stored in ethanol for subsequent DNA analysis and a 10 cm by 10 cm flesh sample was collected from quillback and yelloweye rockfishes for subsequent metal analysis.

Sagittal otoliths from quillback and yelloweye rockfishes were aged in the Pacific Biological Station (PBS) ageing lab, using the burnt section technique for rockfishes (MacLellan, 1997).

### 2.4.2 Catch Rate Calculations

The catch rate (U), as defined in previous years, is the total weight in kilograms of fish per set (Wt) divided by the number of intact skates returned (N) from the set.

$$U_{is} = Wt_{is} / N_i$$

where *s* denotes the species, and *i* denotes the set.

All statistical analyses were performed using SPlus 2000 or Statistix version 7.0.

### 2.4.3 Bathymetric Positional Index

The bathymetric positional index (BPI) is one component of a benthic habitat model being developed and used for the stock assessment of inshore rockfish. The benthic habitat model uses high resolution (5 m) multibeam bathymetry, its derivatives (rugosity, slope, and BPI), and acoustic backscatter data in a multivariate spatial analysis to classify benthic habitat zones. A complete description of the bathymetric positional index and the full benthic habitat model is presented in Lacko *et al.* (*in prep*).

The bathymetric positional index (BPI) measures a point's position relative to the overall terrain or seascape. It is a result of a nearest-neighbour algorithm that compares the elevation of a cell to the mean elevation of the surrounding cells in a circular neighborhood (Iampietro and Kvitek, 2002). Positive BPI values represent bathymetric positions higher than the mean elevation for the specified neighbourhood (elevations) and negative values represent bathymetric positions lower than the mean elevation for the specified neighbourhood (depressions). Those values that fall near zero characterize positions near the mean (flats).

The raster calculator provided by the spatial analyst extension in ArcMap™ 9.1 was used to calculate the BPI rasters using the following equation (Lacko *et al.*, *in prep*):

$$BPI<scalefactor> = int((bathy - focalmean(bathy,annulus,irad,orad)) + .5)$$

where:

scalefactor = fine or broad (see below)  
 bathy = input bathymetric raster  
 irad = inner radius of annulus  
 orad = outer radius of annulus

Two scalefactors were used to bring out fine and broad scale surficial features of the sea floor:

- fine scale - inner radius (irad) = 3-cells, outer radius (orad) = 10-cells
- broad scale - inner radius (irad) = 25 cells, outer radius (orad) = 50-cells

For simplicity, and in the absence of acoustic backscatter data, only the area of the seafloor which had been surveyed with multibeam sonar was classified into three distinct categories using bpi values:

- Zero or Negative BPI = flats/depressions
- Positive BPI (course scale) = slopes/mounds
- Positive BPI (fine scale) = peaks/ridge tops

During gear deployment the vessel's position was tracked in ArcMap™ 9.1 using the vessel's GPS. The vessel's track was used as an estimate of the longline set location on the sea floor. For this analysis, the hooks for each set were assumed to be evenly spaced, 12 feet apart, along the longline. Individual hooks and their associated catch were assigned to one of the three bpi categories (flat/depression, slope/mound, or peak/ridge top) based on their location. The proportion of hooks that yielded quillback and yelloweye rockfish catch were compared among the three bpi categories using pairwise proportion tests. Other rockfish species were not investigated because too few individuals were caught to enable a meaningful habitat-catch comparison.

### 3.0 RESULTS AND DISCUSSION

All data collected on the 2005 survey are archived in DFO's GFBio database and can be retrieved by specifying Trip ID 60506.

#### 3.1 Survey set locations, depths and times

Figure 1 presents a map of the survey area illustrating the boundaries of the statistical areas, the survey grid and the location of the 89 fished sites.

Gear deployment took place between 0637 h and 1808 h and soak time varied from 99 to 127 minutes (mean  $\pm$  95% confidence interval = 119.6  $\pm$  0.61, median=120, mode=119). Fishing took place during daylight hours and gear retrieval was complete by 2025 h. Fifty-one sets were conducted in the shallow stratum (41 – 70 m) and 37 sets in the deep stratum (71 – 100 m). Set 83's modal set depth of 34 m was slightly less than the target depth range but was included as a shallow stratum set. Across all sets, the minimum depths ranged from 28 – 93m, the maximum depths ranged from 37 – 111m, and the modal depths ranged from 34 – 100m (Appendix A).

#### 3.2 Catch Summary

##### 3.2.1. Hook by Hook

A total of 19, 923 hooks were fished during the survey. Fifty-six percent of all hooks retrieved yielded catch, 24% were empty, and 19% were returned with bait (Table 1). Partial fish returning on hooks, usually heads whose bodies were predated, and fish

drop offs at the side of the vessel were uncommon, together making up 1.7% of total hooks retrieved (Table 1).

A total of 23 species and 6 taxonomic groups were caught during the survey, including 7 rockfish and 14 other fish species (Table 2). Spiny dogfish (*Squalus acanthias*) were ubiquitous; occurring in all 89 sets (Table 2). A total of 146 quillback rockfish were observed in 43 of 89 sets and were the most geographically widespread *Sebastes* species in the catch (Table 2). More yelloweye rockfish were caught (211 fish) than quillback rockfish but they were present in only 37 of 89 sets (Table 2). Sunflower starfish (*Pycnopodia helianthoides*) were the most prevalent invertebrate species, found in 22 of 89 sets.

A total of 19 metric tonnes (t) of catch were landed during the 2005 survey (Table 2). The total catch of elasmobranchs was 18 t, which made up 95% of the total landings (Table 2). Spiny dogfish dominated the catch and represented 92% (17.5 t) of the total fish weight. Yelloweye rockfish were ranked second by weight with landings totalling 424 kg. Big skate (*Raja Binoculata*), sixgill shark (*Hexanchus griseus*) and lingcod (*Ophiodon elongates*) were observed in relatively small numbers, but were ranked third, fourth and fifth by weight with each species making up about 1% of the total landed fish weight. Sunflower starfish were ranked sixth by weight, making up 0.8% (0.15 t), and quillback rockfish ranked seventh, making up 0.6% (0.11 t) of the total fish landings. Canary (*S. pinniger*) and copper (*S. caurinus*) rockfish were much less common with landings of 0.14% (26 kg) and 0.22% (42 kg) of the total fish weight, respectively. Tiger (*S. nigrocinctus*), greenstriped (*S. elongatus*) and redstripe (*S. proriger*) rockfish were present in the catch, but were rare with total landings of 5 kg or less each.

All rockfish species and most other fish species were more commonly caught in the shallow stratum (Table 3, 4). Canary, redstripe, and tiger rockfishes were absent from sets conducted in the deep stratum (Table 3).

### **3.2.2 Biological Sampling**

A total of 6013 fish were sampled on the survey, including 5449 spiny dogfish sampled for L/S and 412 rockfish sampled for L/W/S/M/O (Table 2). Figure 2 illustrates fork length frequency histograms by sex for all rockfish species taken on the survey and Table 5 presents rockfish fork length descriptive statistics.

Quillback rockfish fork lengths ranged from 234 – 410 mm, with a mean of 339 mm (Figure 2, Table 5). There were no significant differences in mean fork lengths between depth strata or sexes (Table 6). One-way analysis of variance revealed significant differences in fork lengths among statistical areas (Table 6). Pairwise comparisons of means show that quillback rockfish fork lengths in SA 15 and 29 were significantly smaller than those from statistical areas 17, 18 and 28 (Table 6).

Yelloweye rockfish fork lengths ranged from 277 – 675 mm (Figure 2, Table 5). No significant differences were found between depth strata, sexes or statistical areas (Table 6).

The fork length (mm) to weight (g) relationship for rockfish can be expressed as:

$$\text{Weight} = a \text{ Length}^b$$

Constants were calculated for quillback and yelloweye rockfishes. These 2005 estimates are similar to those obtained in 2003 and 2004 (Lochead and Yamanaka, 2004; Lochead and Yamanaka, 2006):

quillback rockfish	$a = 0.537(10^{-6})$	$b = 3.21$	(Figure 3)
yelloweye rockfish	$a = 0.467(10^{-6})$	$b = 3.22$	(Figure 3)

The plot of proportion female by species illustrates strongly skewed sex ratios for a few species (Figure 4). Canary rockfish were 70% female (n=10), lingcod were 85% female (n = 41), and spotted ratfish were 77% female (n=48). Males dominated the catch for big skate which were 67% male (n=21), copper rockfish which were 62% male (n=29), and quillback rockfish which were 64% male (n=136).

The longline gear employed on the survey, coupled with the survey's depth range, generally targeted adult fish. Over 77% of all rockfish captured on the 2005 survey were sexually mature (Table 7). Only 23% of male rockfish and 27% of female rockfish were 'immature' or 'maturing'. The majority of males (69%) and females (77%) were observed to be 'resting' or 'developing' (Table 7), which is consistent with the reproductive cycle of these species (Love *et al.*, 2002).

Age frequency distributions were plotted by sex for quillback rockfish (Figure 5). Ages ranged from 6 to 46, with a mean age of 19 (Table 8). The most frequently observed age was 11 (Table 8). No significant differences in quillback mean age were found among statistical areas, depth strata, or sexes (Table 9).

Age frequency distributions were also plotted by sex for yelloweye rockfish (Figure 6). Ages ranged from 5 to 65, with a mean age of 25 and a modal age of 19 (Table 8). Yelloweye rockfish mean ages were not significantly different among statistical areas, depth strata, or sexes (Table 9).

An adequate sample size of yelloweye rockfishes allowed estimates of von Bertalanffy growth parameters  $L_{\infty}$ ,  $k$  and  $t_0$ , to be derived from the 2005 yelloweye rockfish biological sampling data (Table 10). The von Bertalanffy (1938) growth equation models the relationship between fish length (mm) and age (years):

$$L_t = L_{\infty} [1 - e^{-K(t-t_0)}]$$

where:  $L_t$  = fork length at age  $t$

$L_{\infty}$  = maximum (asymptotic) fork length  
 K = growth constant  
 t = age  
 $t_0$  = theoretical age when length equals zero

The estimate of  $L_{\infty}$  was larger for female yelloweye rockfishes than it was for males (Table 10). This is what is expected given that female rockfish grow to a slightly larger size than males (Love *et al.*, 2002).

### 3.2.3 Catch Rates

Catch rate variability was high for most species captured on the survey (Table 11). This is expected on a longline survey where a broad range of depths and habitat types are encountered within a single string of gear. Spiny dogfish were captured in large numbers throughout the survey (Table 2). The catch rate coefficient of variation was 0.45 for spiny dogfish, a value that was an order of magnitude lower than it was for all other species (Table 11). This survey is likely to provide a reliable index of abundance for spiny dogfish. Quillback and yelloweye rockfishes catch rate CVs were 1.69 and 1.93, respectively. These values are slightly higher than those obtained in previous years. In 2003 and 2004, quillback rockfish catch rate CVs were 1.51 and 1.06, respectively, and yelloweye rockfish catch rate CVs were 1.81 and 1.50, respectively (Lochead and Yamanaka, 2004, 2006). Given the catch rate variability for these species, this survey is conforming to the initial expectation that it will provide useful relative indices of abundance for quillback and yelloweye rockfishes (Lochead and Yamanaka, 2004).

Overall mean rockfish catch rates ranged from 0.002 kg/skate for redstripe rockfish up to 2.38 kg/skate for yelloweye rockfish (Table 12). Quillback rockfish had the second highest mean catch rate of 0.62 kg/skate (Table 12). With catch rate data for pooled statistical areas, all rockfish had median catch rates equal to zero indicating that all rockfish were absent from at least half of the skates fished.

Quillback rockfish and yelloweye rockfish catch rates were highly variable with respect to start deployment time, sea state (Appendix B), tide and lunar phase, and no consistent trends were observed (Figures 7).

The spatial distributions of 2005 catch rates (kg/skate) were plotted by statistical area for all rockfish species and lingcod (Figures 8 – 15). No rockfish species were caught in SA 20, but all other SAs had at least one rockfish species present in the catch. SAs 16 and 17 had the highest rockfish species diversity with 6 of the 7 observed rockfish species present. Lingcod were encountered in low numbers throughout the survey area and were not caught in SAs 19 and 29 (Figure 15). The highest individual lingcod catch per set was 9 fish and this was achieved in one set in SA 14 and one other in SA 17.

The spatial distribution of rockfish catch rates varied greatly by species (Figures 8 – 14, Table 13). Canary rockfish were infrequently encountered and were observed in

only two sets, one in SA 16 and one in SA 17. Small catches of copper rockfish were present in 12 sets distributed among SA 14 – 19. The highest catch of copper rockfish was 8.5 kg/skate from a shallow set conducted on the northeast side of Hornby Island. A total of 2.4 kg (8 fish) of greenstriped rockfish was present in 7 sets located in SA 14, 15, 16, 17 and 28. Small catches of tiger rockfish were present in 3 sets, one fish in SA 14, one in SA 16, and one in SA 17. Only one redstripe rockfish was caught on the survey east of Bowen Island in SA 28. Quillback rockfish catches were never more than 6.2 kg/skate and were distributed throughout all the SAs surveyed, except SA 20. The highest catch of quillback rockfish was from a set located between Denman and Hornby Islands, in Lambert Channel. Yelloweye rockfish catches were highest in SAs 14, 15, and 16 and decreased to the south. The southern boundary for yelloweye rockfish catch was 48° 41' N. Yelloweye rockfish were not caught in SAs 19, 20 or 28.

Catch rates by species were plotted against modal set depths for the six most frequently encountered rockfish species in 2005 (Figure 16). These plots illustrate peaks in abundance within species specific depth ranges. Modal set depths at peak catch rates for canary, copper, greenstriped, quillback, tiger, and yelloweye rockfishes were 51, 44, 76, 50, 51, and 55 metres, respectively.

Quillback and yelloweye rockfish catch rates (kg/skate) were compared between depth strata. No significant differences were found for either species (Table 14 and 15).

Spiny dogfish, lingcod, quillback rockfish and yelloweye rockfish catch rates from all three survey years (2003, 2004 and 2005) were plotted by statistical area (Figure 17) and Kruskal-Wallis tests were used to test for differences among statistical areas (Table 16). Spiny dogfish catch rates were lowest in SA 12. Spiny dogfish catch rates from SA 12 were significantly lower than those from SA 13, 14, 16, 17, and 18. Lingcod catches were absent from SA 19 and were highest in SA 14 and 17, but no significant differences were detected among areas (Table 16).

Quillback rockfish catch rates showed an increasing trend with latitude (Figure 11.). Quillback rockfish catch rates from statistical area 12 were significantly higher than those from SA 15, 16, 17, 18, 19, and 20, but were not different from SA 13, SA 14, SA 28 and 29, and catch rates from SA 13 were significantly higher than those from SA 16 (Table 16). Yelloweye rockfish catch rates were highest in SA 13, 15 and 16 (Figure 14). Yelloweye rockfish catch rates from SA 13 and 15 were significantly higher than those from SA 12, 17, 18, 19, 20, 28 and 29, and SA 16 catch rates were significantly higher than SA 18, 19, 20 and 29 (Table 16).

### **3.3 Bathymetric Position Index**

A total of 31 longline sets from the 2005 survey were located in areas which have been acoustically surveyed with multibeam sonar (Figure 18). Bathymetry derived from the multibeam surveys was used to calculate Bathymetric Position Index classes and catch rates were then analyzed relative to the BPI classes (Figure 18).

The proportion of the total occupied hooks by species (or species group) varied greatly by BPI classes (Figure 19). Flatfish and skates were primarily observed over flats/depressions, sculpins, rockfish, and lingcod were most commonly caught on the peaks/ridge tops, whereas spiny dogfish were present on all three BPI categories (Figure 19). When the rockfish species group was broken down into individual species, various patterns were observed (Figure 19). Tiger rockfish and greenstriped rockfish were caught on peaks/ridge tops only, copper rockfish on peaks/ridge tops and slopes/mounds, and yelloweye rockfish and quillback rockfish were observed on all three BPI classes (Figure 19). The only redstripe rockfish taken on the survey was located on the flats/depression BPI category (Figure 19), but this distribution pattern is based on a very low sample size.

Proportion tests were used to test for differences in the proportion of the total hooks that yielded quillback rockfish and yelloweye rockfish among the three BPI categories (Table 17). The proportion of total hooks that yielded a quillback rockfish was significantly lower on the flats/depressions than on the slopes/mounds and peaks/ridge tops (Table 17). For yelloweye rockfish, the proportion of hooks yielding a catch was significantly lower on the flats/depressions category than it was on the peaks/ridge tops (Table 17).

A correspondence analysis was performed to visually present and quantify the interaction between species (or species group) and BPI category (Figures 20 and 21). The distance between the slope class point and the species (or species group) was used as a measure of their association. Results of the correspondence analysis indicate that flatfish and skates were associated with the flats/depressions category, lingcod associated with the peaks/ridge tops, rockfish and sculpins were associated to both slopes and peaks, and spiny dogfish were not associated with any one BPI category (Figure 20). Individual rockfish species patterns emerged (Figure 21). Yelloweye rockfish were equally associated with peaks/ridge tops and slopes/mounds, quillback rockfish were highly associated with slopes/mounds, copper, tiger and greenstriped rockfish were weakly associated with peaks/ridge tops, and the one redstripe rockfish was weakly associated with flats/depressions (Figure 21).

When hooks from all BPI slope categories were combined, quillback rockfish and yelloweye rockfish catch rate (#fish/hook) coefficients of variation were 12.5 and 10.6, respectively (Table 18). When catch rates were calculated by BPI category, catch rate (#fish/hook) coefficients of variation were highest on flats/depressions, and lowest on slopes/mounds and peaks/ridge tops (Table 18). Catch rate CV's for all categories combined were reduced by 8 – 18% when flats/depressions were not considered (Table 18).

#### 4.0 CONCLUSIONS

The 2005 survey completed the initial collection of fishery-independent catch rate and accompanying biological data for the inside waters between Vancouver Island and the mainland (SA 12 to 20, 28 and 29). With all statistical areas now surveyed, spatial

trends in relative abundance were analysed. Quillback rockfish catch rates were low (mean catch rate = 0.62 kg/skate) in the Strait of Georgia SAs 14 – 29 and were approximately one fifth of those observed in SAs 12 and 13 (mean catch rates = 3.01 – 3.24 kg/skate) (Lochead and Yamanaka, 2006). Yelloweye rockfish catch rates were also low in the southern region of the Strait of Georgia SAs 18 – 29 (mean catch rates = 0 – 0.35 kg/skate). In the central region of the Strait of Georgia SAs 14-17 yelloweye rockfish catch rates were highly variable (mean catch rate = 1.56 – 5.20 kg/skate), and were similar to rates observed in the northern regions SAs 12 and 13 (mean catch rate = 2.78 – 2.84 kg/skate) (Lochead and Yamanaka, 2006).

Rockfish species diversity was considerably lower in SA 14-20, 28 and 29 than in SA 12 and 13 (Lochead and Yamanaka 2004, 2006). A total of seven rockfish species were encountered in 2005, versus a total of 14 for the previous years.

Habitat is an important influence on the distribution rockfishes. Variation in substrate type and slope are major contributors to the variation in catch rates among sets. The distribution of catch on longline gear varied with BPI slope classes. BPI's may be used to improve future survey design by allowing specific slope classes to be targeted to reduce catch rate variability.

Additional research on catchability and interspecific competition for hooks for inshore species is recommended for future surveys, to improve our understanding of the catch rate – abundance relationship.

## ACKNOWLEDGEMENTS

We would like to sincerely thank the scientific staff who conducted the survey: Candace Boyle, Lorna Cameron, Chris Grandin, Todd Johansson and Jonathan Martin. Thanks also to the crew of the *CCGS Neocaligus*, Captain Alan Young, Captain Bob Barker, Bruce Bournazel, Timothy Burrows, Devin Ciccone, Rob Cottrel, and Ray Reardon for their hard work on the survey. Thanks to Chris Grandin for programming the Allegro CE™, designing the Microsoft Access database and assisting with the correspondence analysis, to the Ageing Lab at the Pacific Biological Station for promptly ageing our otolith samples, to Norm Olsen for writing and providing the survey software used to randomly select replacement survey blocks, and to Lisa Lacko for creating the random site generator and performing the bathymetric position index calculations. We are grateful for the multibeam bathymetry data collected and provided by the Canadian Hydrographic Service and the Pacific Geoscience Centre of Natural Resources Canada. Thank you to Chris Grandin and Dana Haggarty for reviewing this document.

SA 16 significantly different than SA 18, 19, 20 and 29

Table 17. Proportion of hooks yielding quillback and yelloweye rockfish catch for the three BPI categories: flats/depressions, slopes/mounds, and peaks/ridge tops. Results of pairwise proportion tests indicate where significant differences were found.

**Quillback Rockfish:**

<b>BPI Category</b>	<b>Total # of hooks</b>	<b>Total # of Quillback</b>	<b>Proportion Quillback</b>
Flats / depressions	2494	4	0.0016
Slopes / mounds	851	8	0.0094
Peaks / ridge tops	3370	31	0.0092

Proportion Test:

Flats / depressions significantly different than Slopes / mounds ( $Z = -2.95$ ,  $p = 0.0031^*$ )

Flats / depressions significantly different than Peaks / ridge tops ( $Z = -3.56$ ,  $p = 0.0004^*$ )

**Yelloweye Rockfish:**

<b>BPI Category</b>	<b>Total # of hooks</b>	<b>Total # of Yelloweye</b>	<b>Proportion Yelloweye</b>
Flats / depressions	2494	12	0.0048
Slopes / mounds	851	9	0.0106
Peaks / ridge tops	3370	38	0.0113

Proportion Test:

Flats / depressions significantly different than Peaks / ridge tops ( $Z = -2.52$ ,  $p = 0.0118^*$ )

Table 18. Quillback and yelloweye rockfish catch rate (#fish/hook) coefficients of variation by BPI category, and for all categories combined.

<b>Species</b>	<b>All</b>	<b>Flats / Depressions</b>	<b>Slopes / Mounds</b>	<b>Peaks / Ridge Tops</b>
Quillback Rockfish	12.5	25	10.3	10.4
Yelloweye Rockfish	10.6	14.4	9.7	9.4

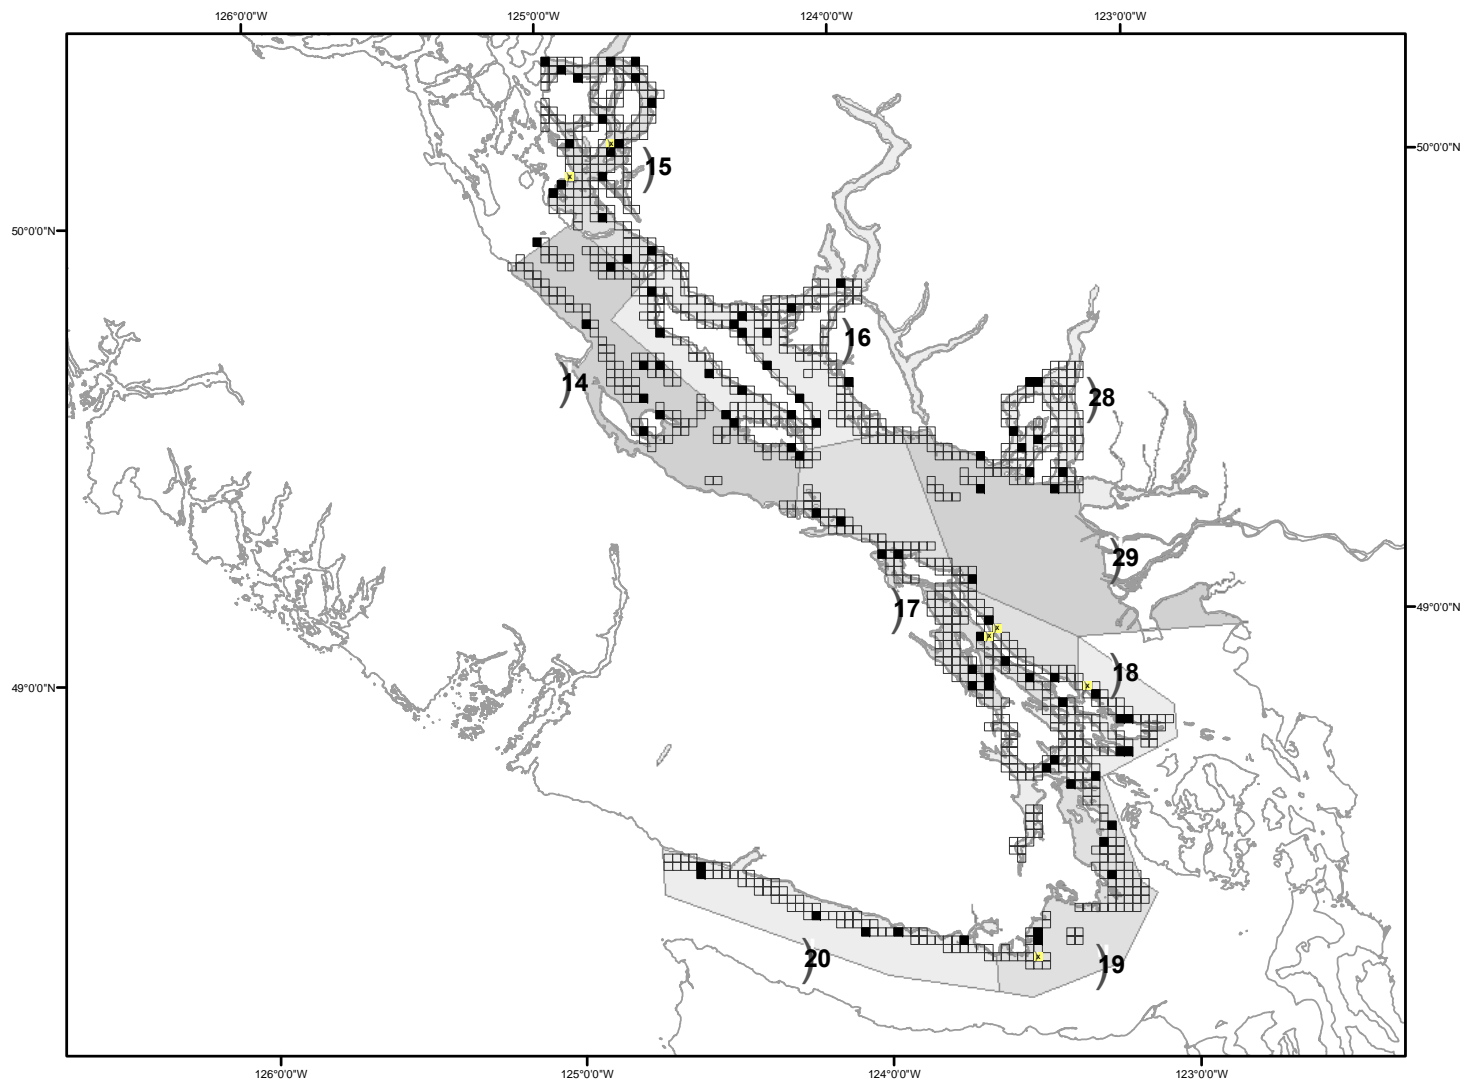

Figure 1. Survey block locations: black squares illustrate the 89 surveyed sites, and black X 's illustrate the 6 rejected blocks. Statistical areas are labelled with boxed numbers 14 – 20, 28 and 29, and their areas denoted with grey shading.

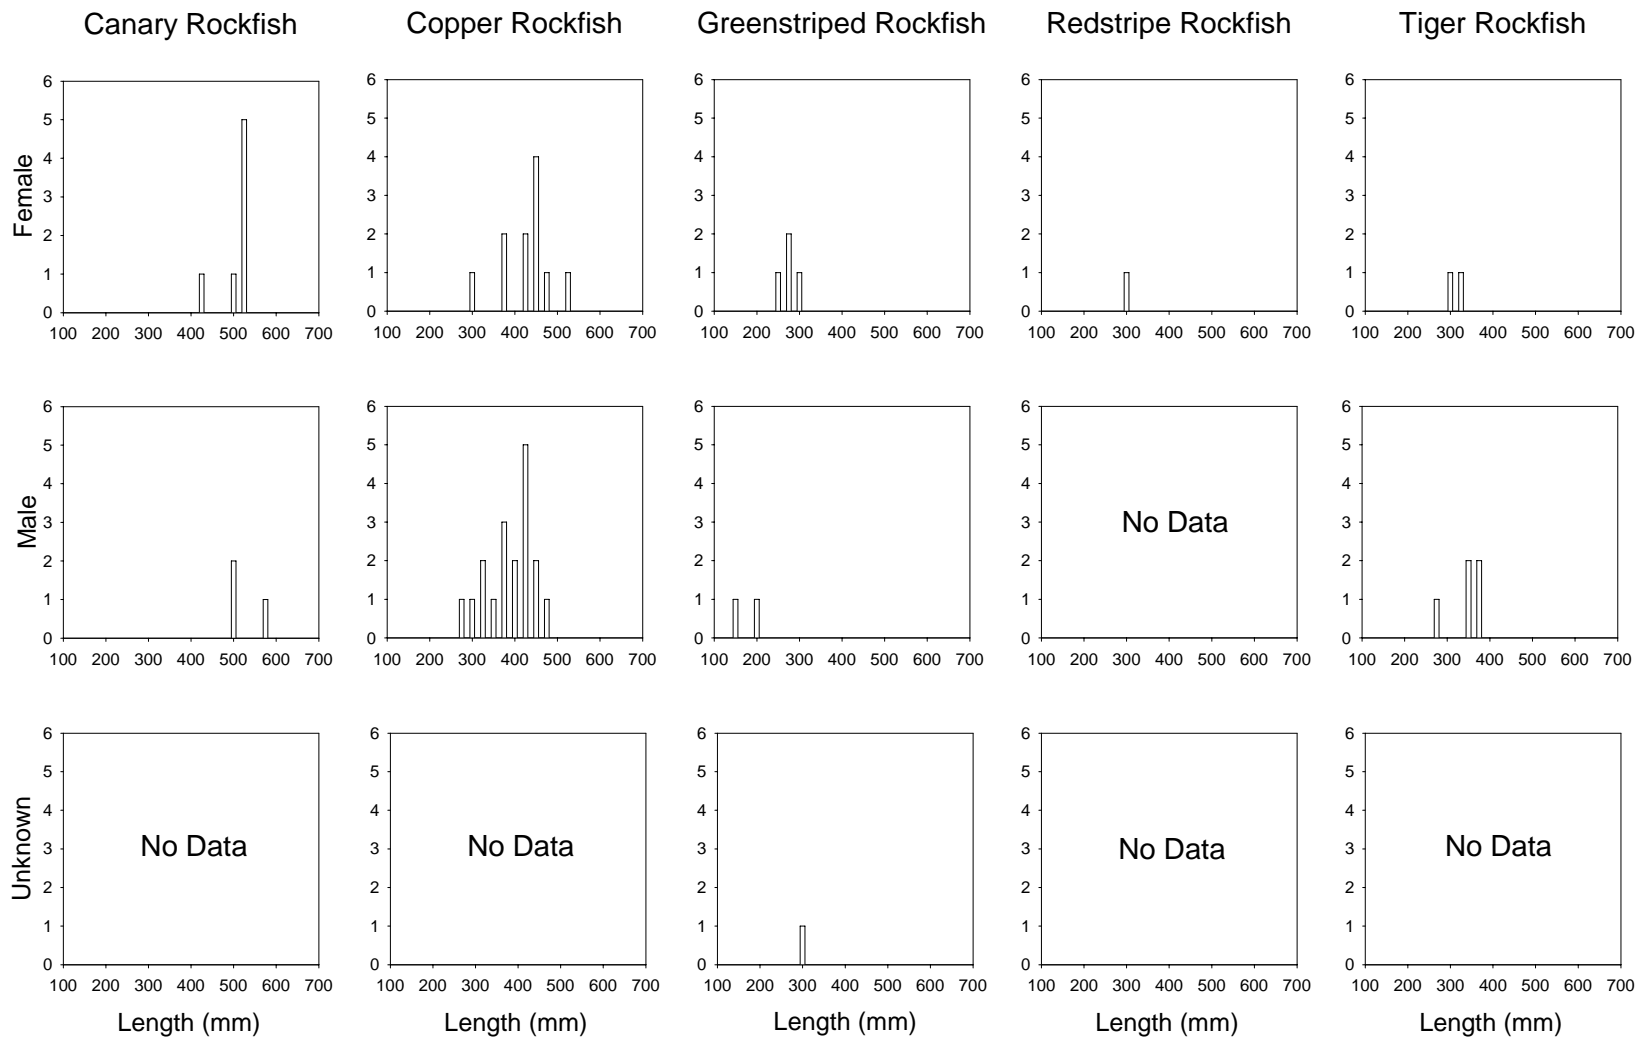

Figure 2. Canary, copper, greenstriped, redstripe, tiger rockfish length frequency histograms.

### Quillback Rockfish

### Yelloweye Rockfish

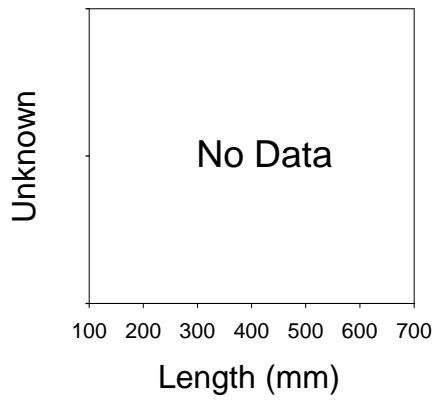

Figure 2 (continued).

## Quillback Rockfish

## Yelloweye Rockfish

Figure 3. Length – weight relationship for quillback and yelloweye rockfish. Line equations are shown where ‘W’ equals weight in grams, ‘L’ equals fork length in millimetres and ‘n’ equals sample size.

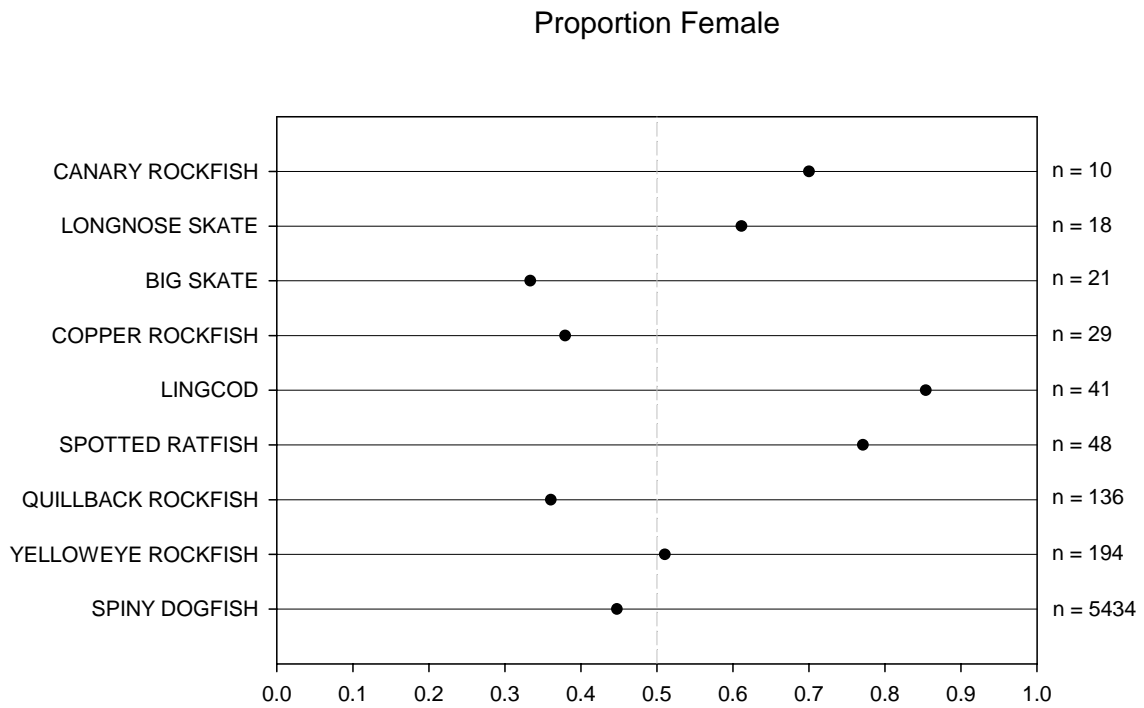

Figure 4. Proportion female for species where sample size (n) was 10 or more.

Figure 5. Age frequency distribution of quillback rockfish plotted with sexes combined (top), with males only (middle), and females only (bottom).

Figure 6. Age frequency distribution of yelloweye rockfish plotted with sexes combined (top), with males only (middle), and females only (bottom).

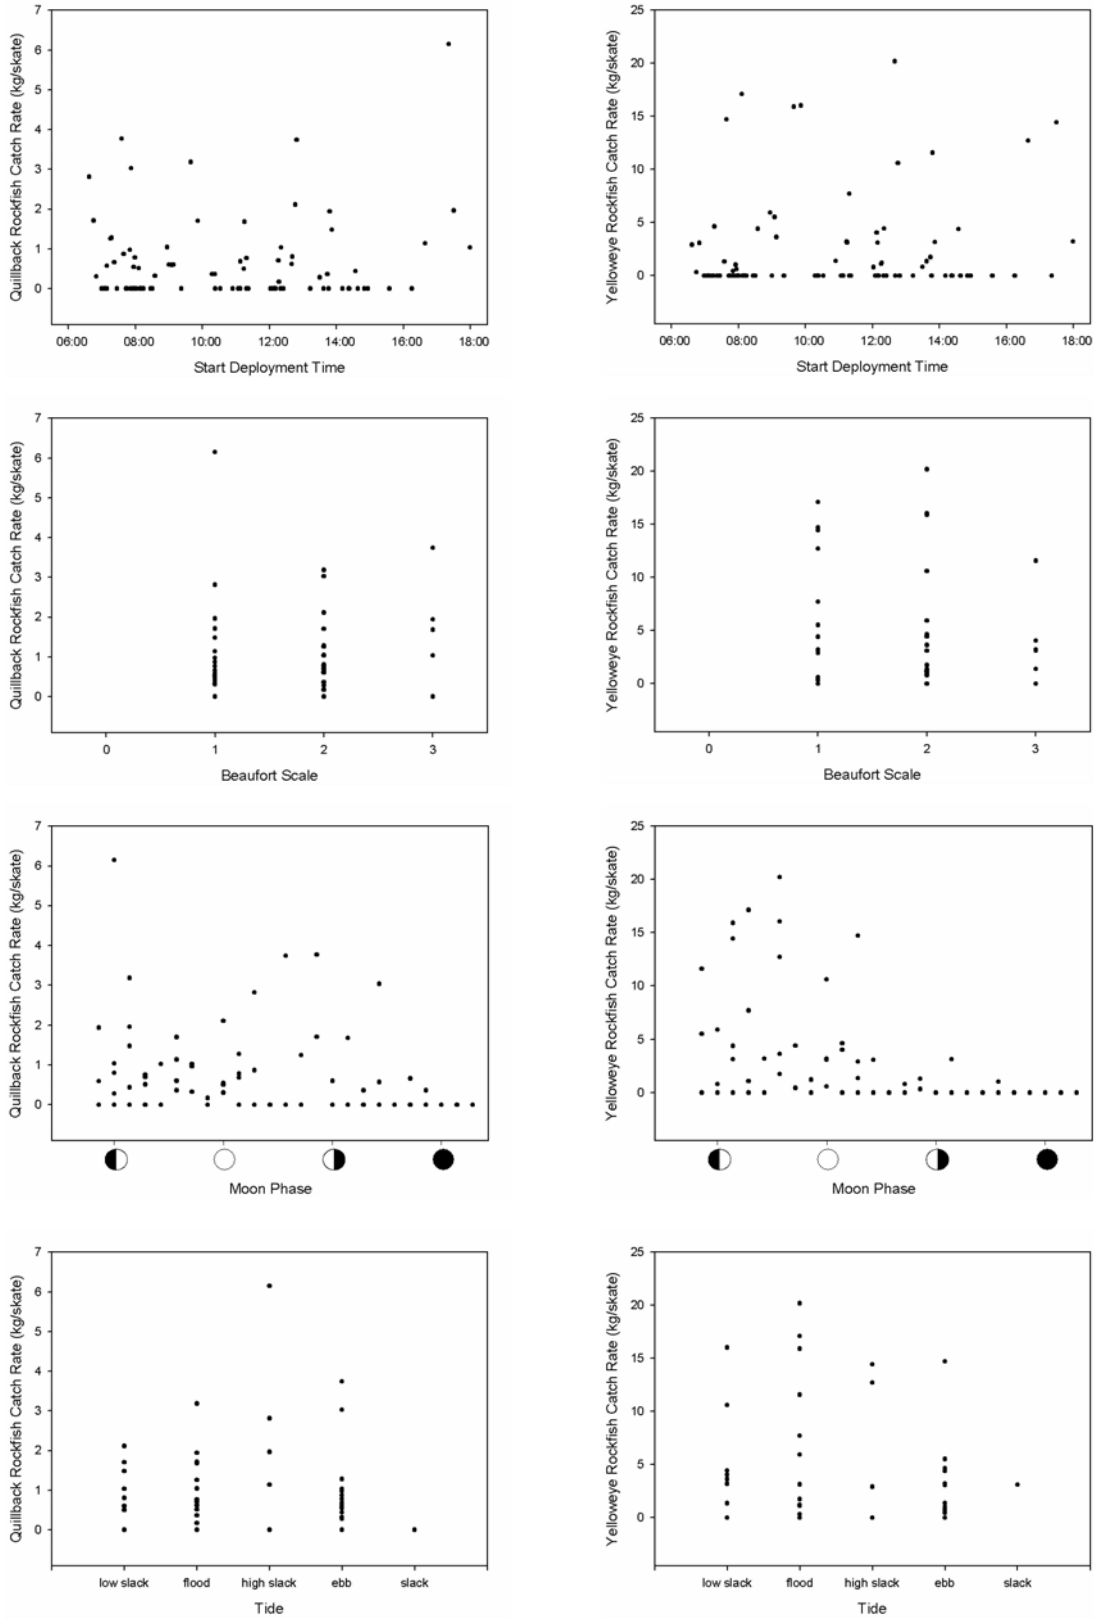

Figure 7. Quillback and yelloweye catch rates (kg/skate) plotted against deployment time, Beaufort scale, moon phase and tide.

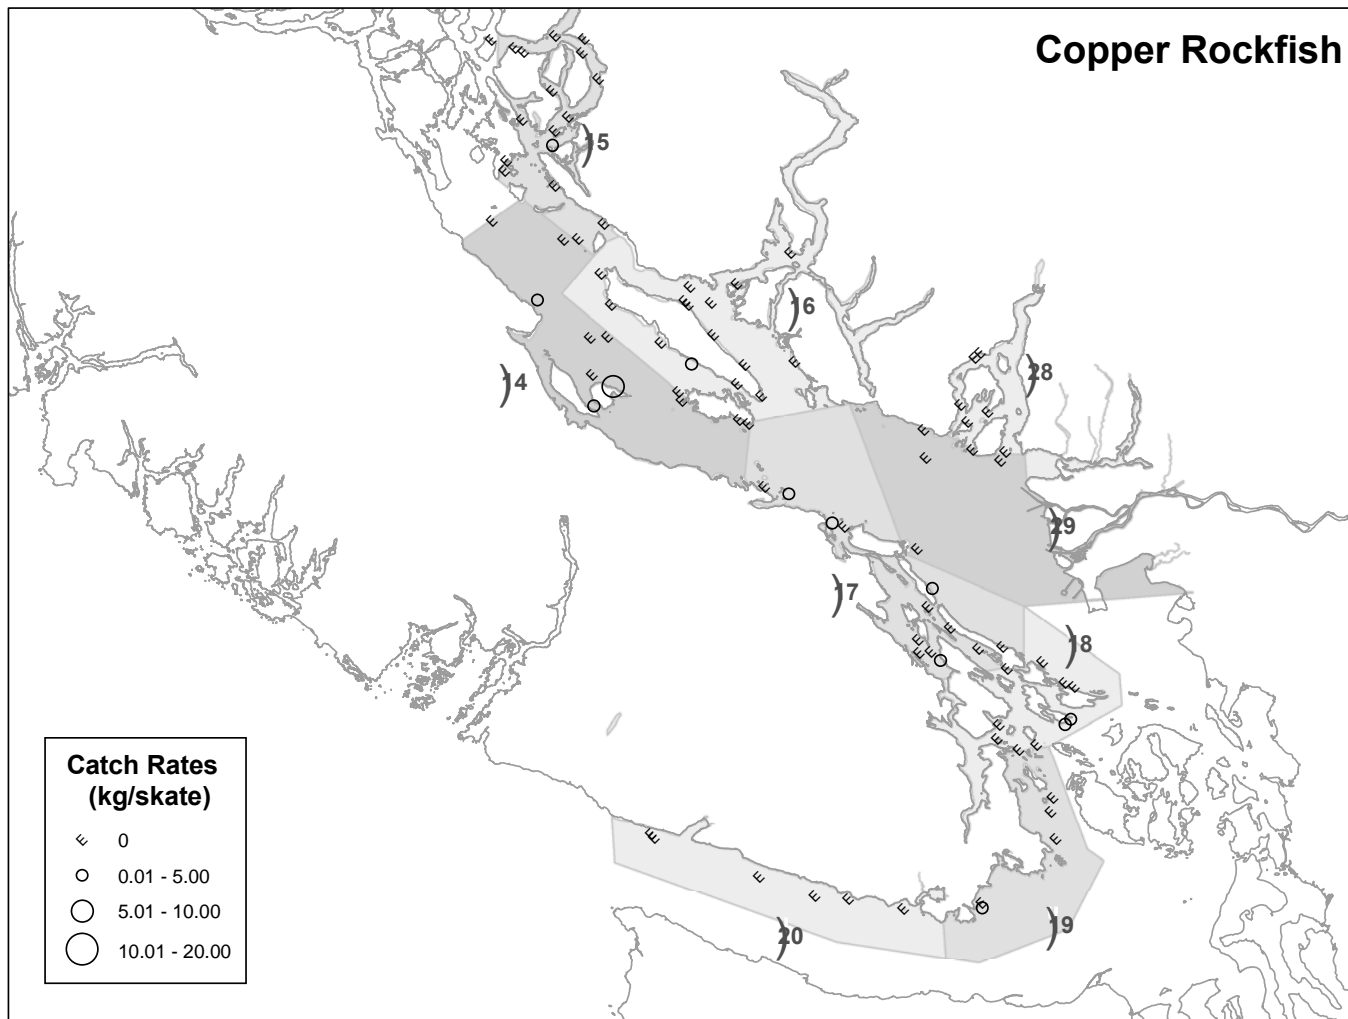

Figure 8. Spatial distribution of copper rockfish catch rates in units of kilograms per skate for all sites surveyed in 2005. Statistical areas are labelled with boxed numbers 14 – 20, 28 and 29, and their areas denoted with grey shading.

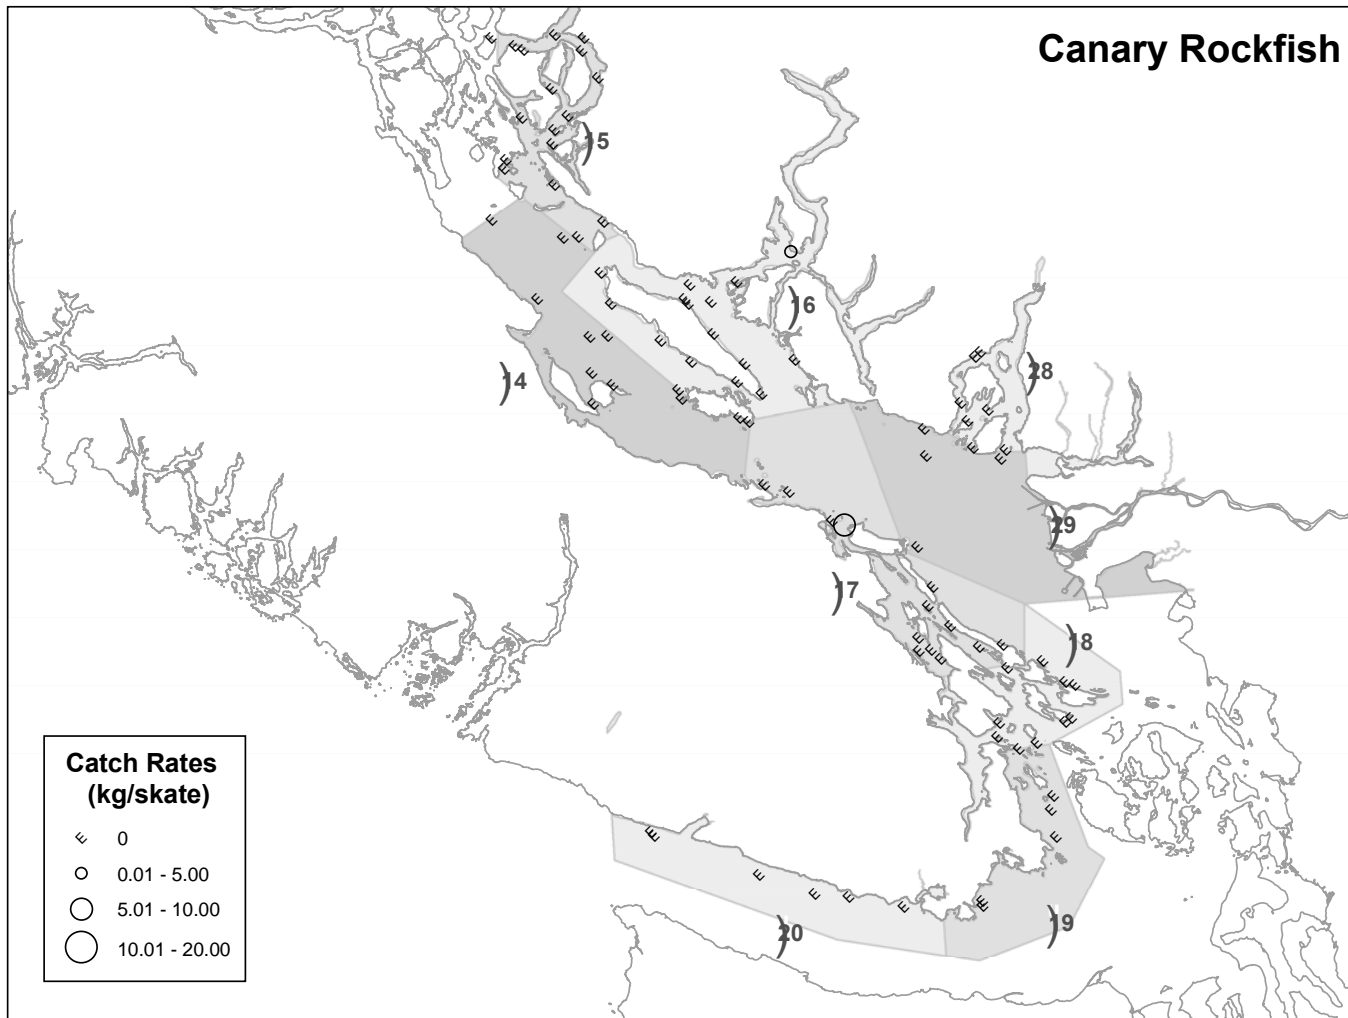

Figure 9. Spatial distribution of canary rockfish catch rates in units of kilograms per skate for all sites surveyed in 2005. Statistical areas are labelled with boxed numbers 14 – 20, 28 and 29, and their areas denoted with grey shading.

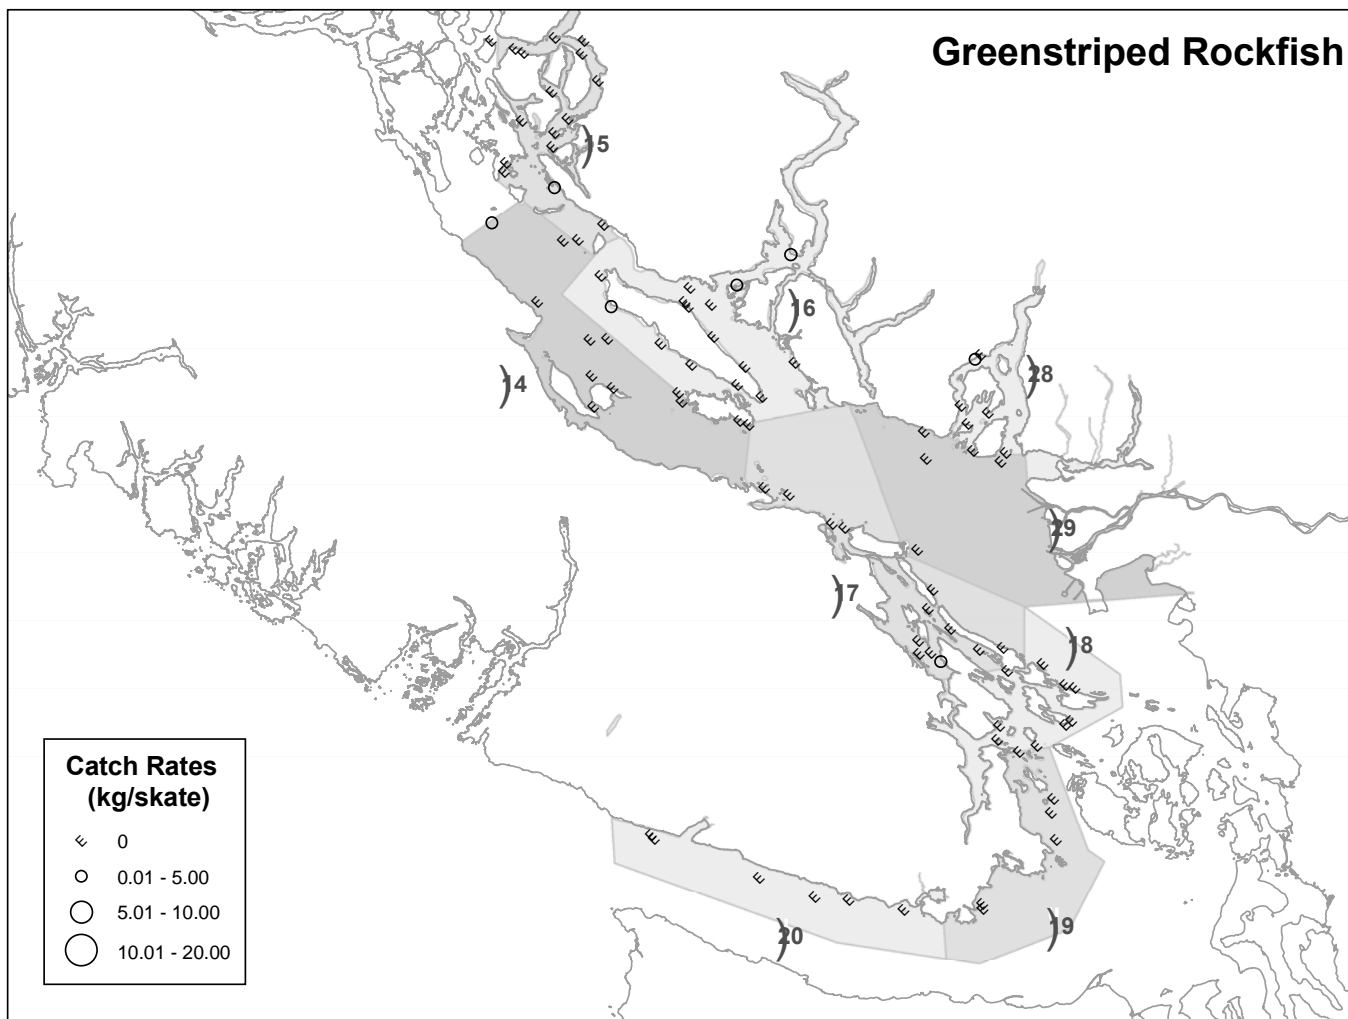

Figure 10. Spatial distribution of greenstriped rockfish catch rates in units of kilograms per skate for all sites surveyed in 2005. Statistical areas are labelled with boxed numbers 14 – 20, 28 and 29, and their areas denoted with grey shading.

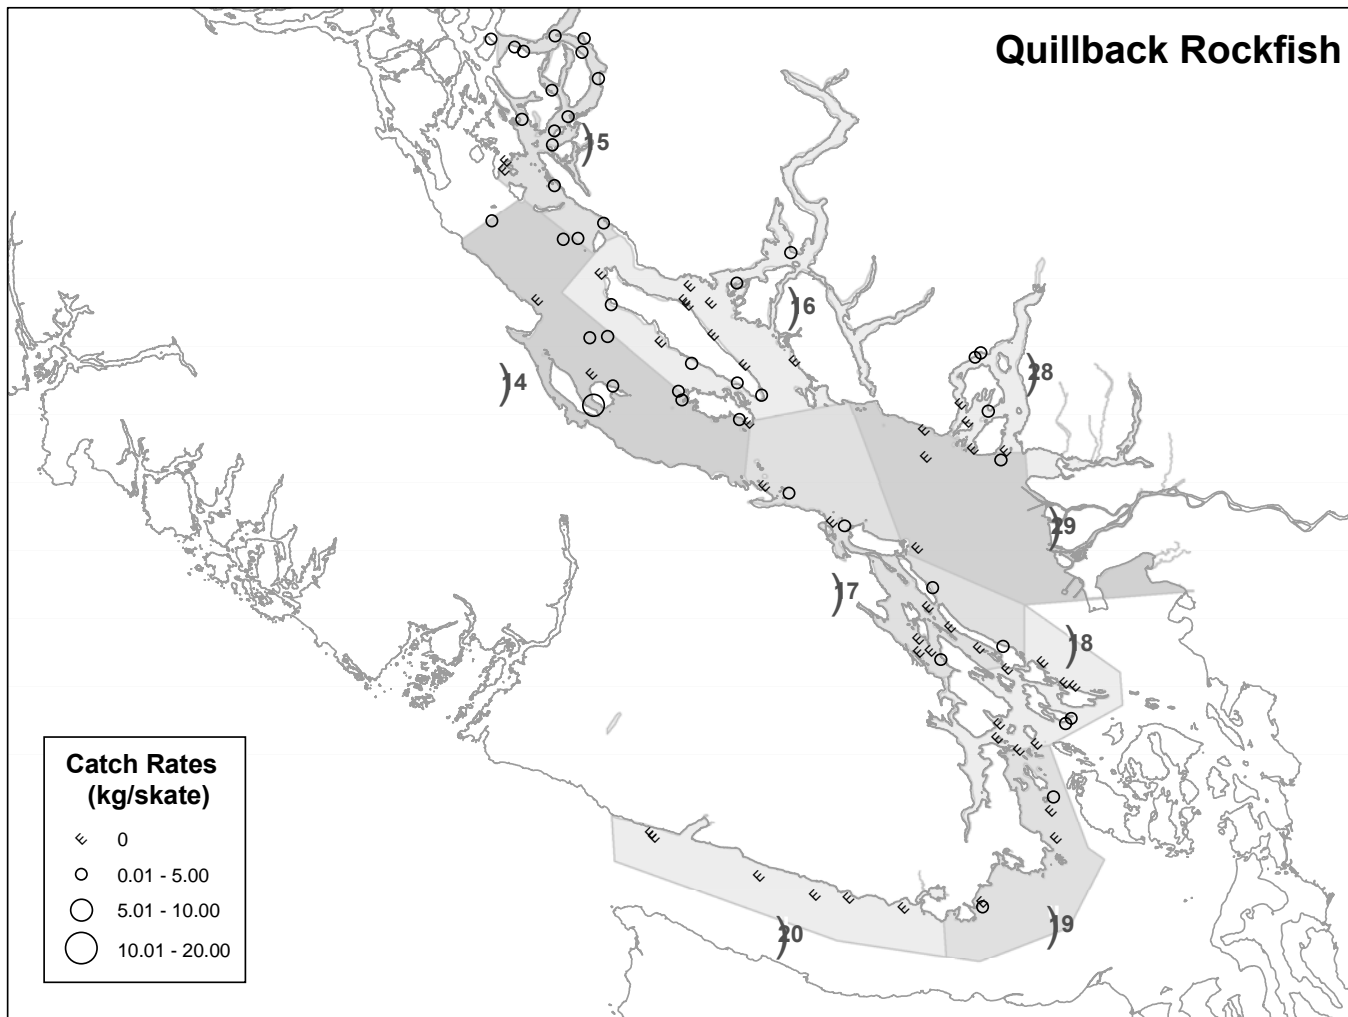

Figure 11. Spatial distribution of quillback rockfish catch rates in units of kilograms per skate for all sites surveyed in 2005. Statistical areas are labelled with boxed numbers 14 – 20, 28 and 29, and their areas denoted with grey shading.

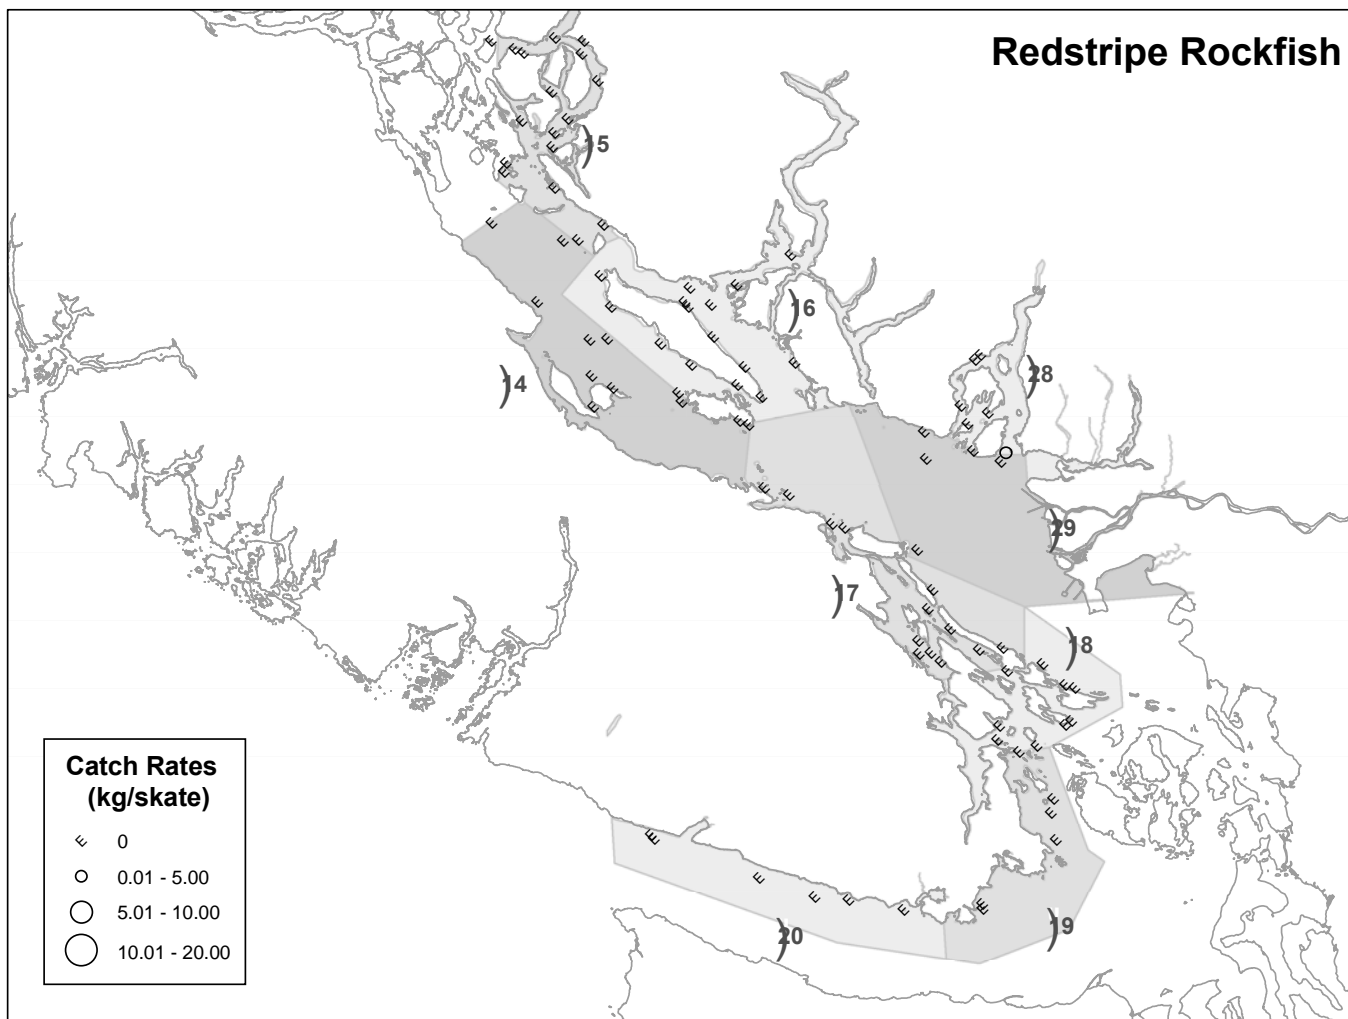

Figure 12. Spatial distribution of redstripe rockfish catch rates in units of kilograms per skate for all sites surveyed in 2005. Statistical areas are labelled with boxed numbers 14 – 20, 28 and 29, and their areas denoted with grey shading.

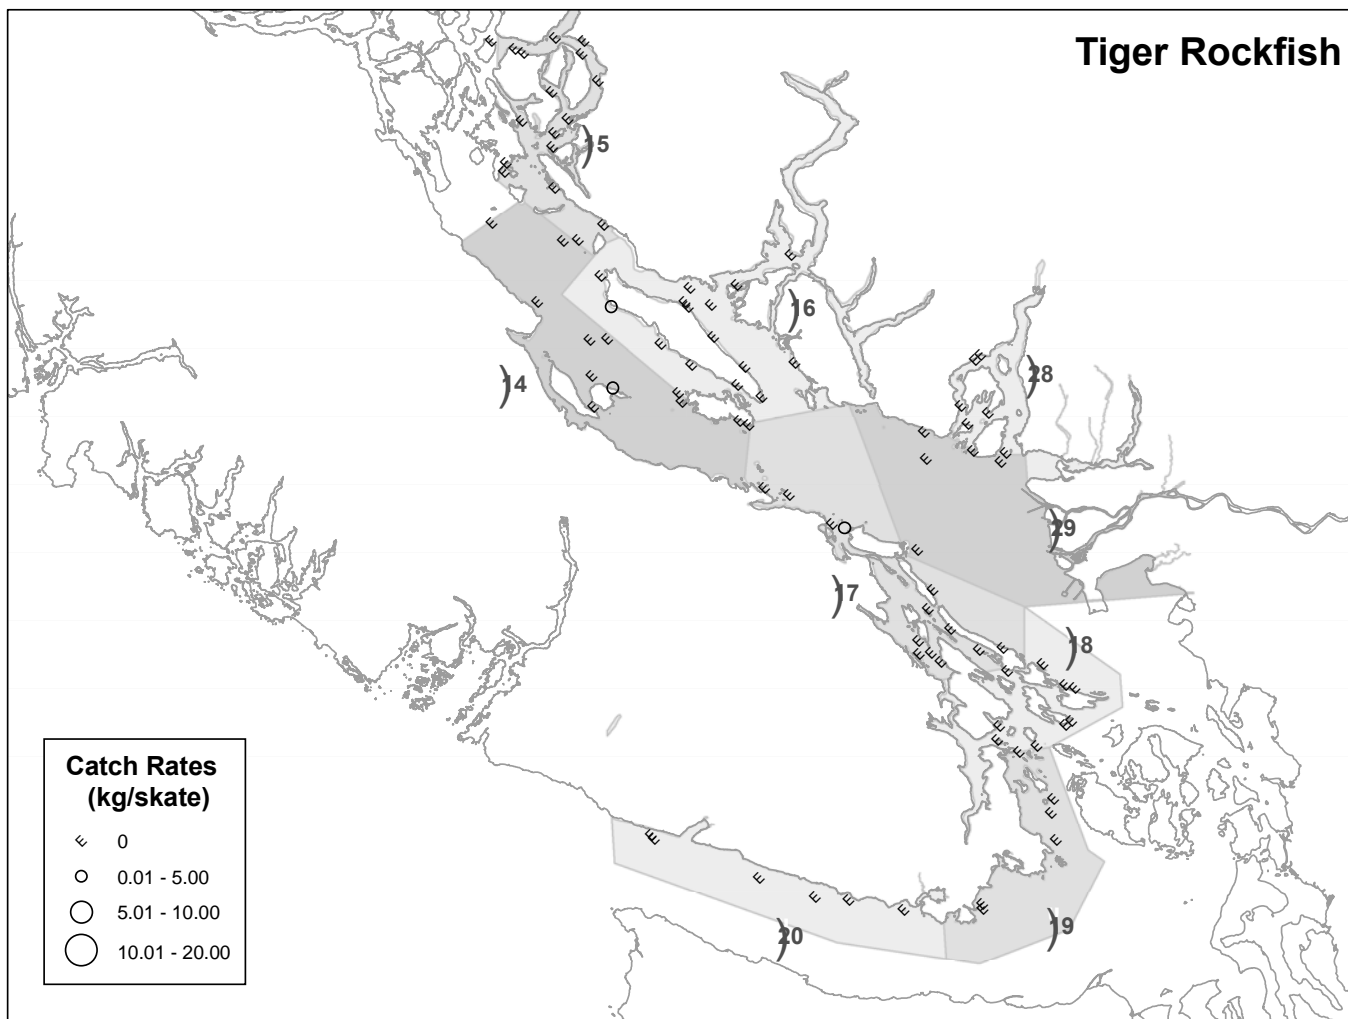

Figure 13. Spatial distribution of tiger rockfish catch rates in units of kilograms per skate for all sites surveyed in 2005. Statistical areas are labelled with boxed numbers 14 – 20, 28 and 29, and their areas denoted with grey shading.

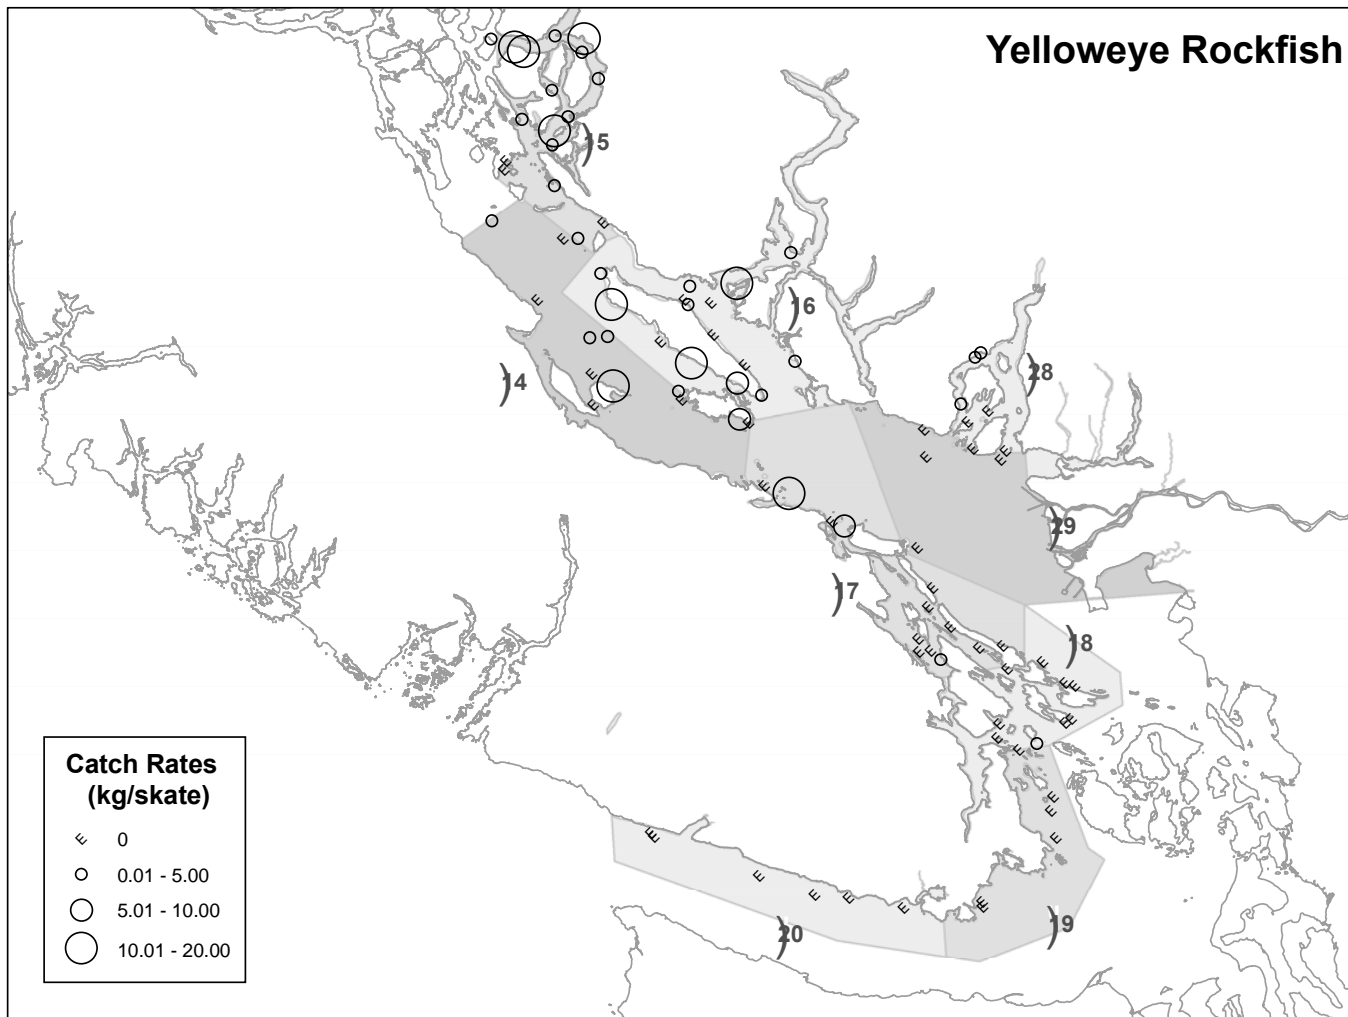

Figure 14. Spatial distribution of yelloweye rockfish catch rates in units of kilograms per skate for all sites surveyed in 2005. Statistical areas are labelled with boxed numbers 14 – 20, 28 and 29, and their areas denoted with grey shading.

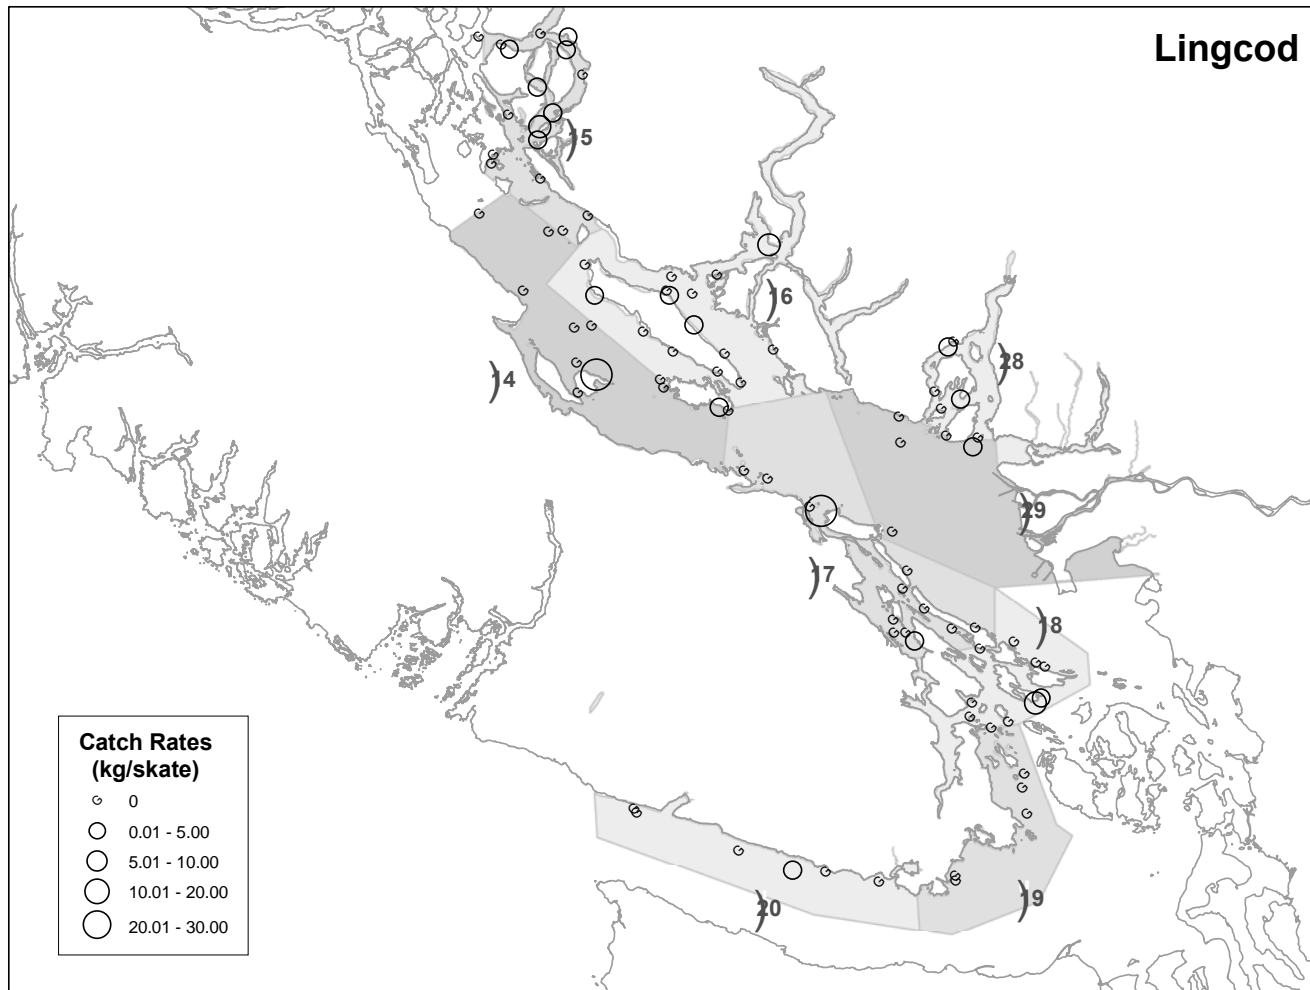

Figure 15. Spatial distribution of lingcod catch rates in units of kilograms per skate for all sites surveyed in 2005. Statistical areas are labelled with boxed numbers 14 – 20, 28 and 29, and their areas denoted with grey shading.

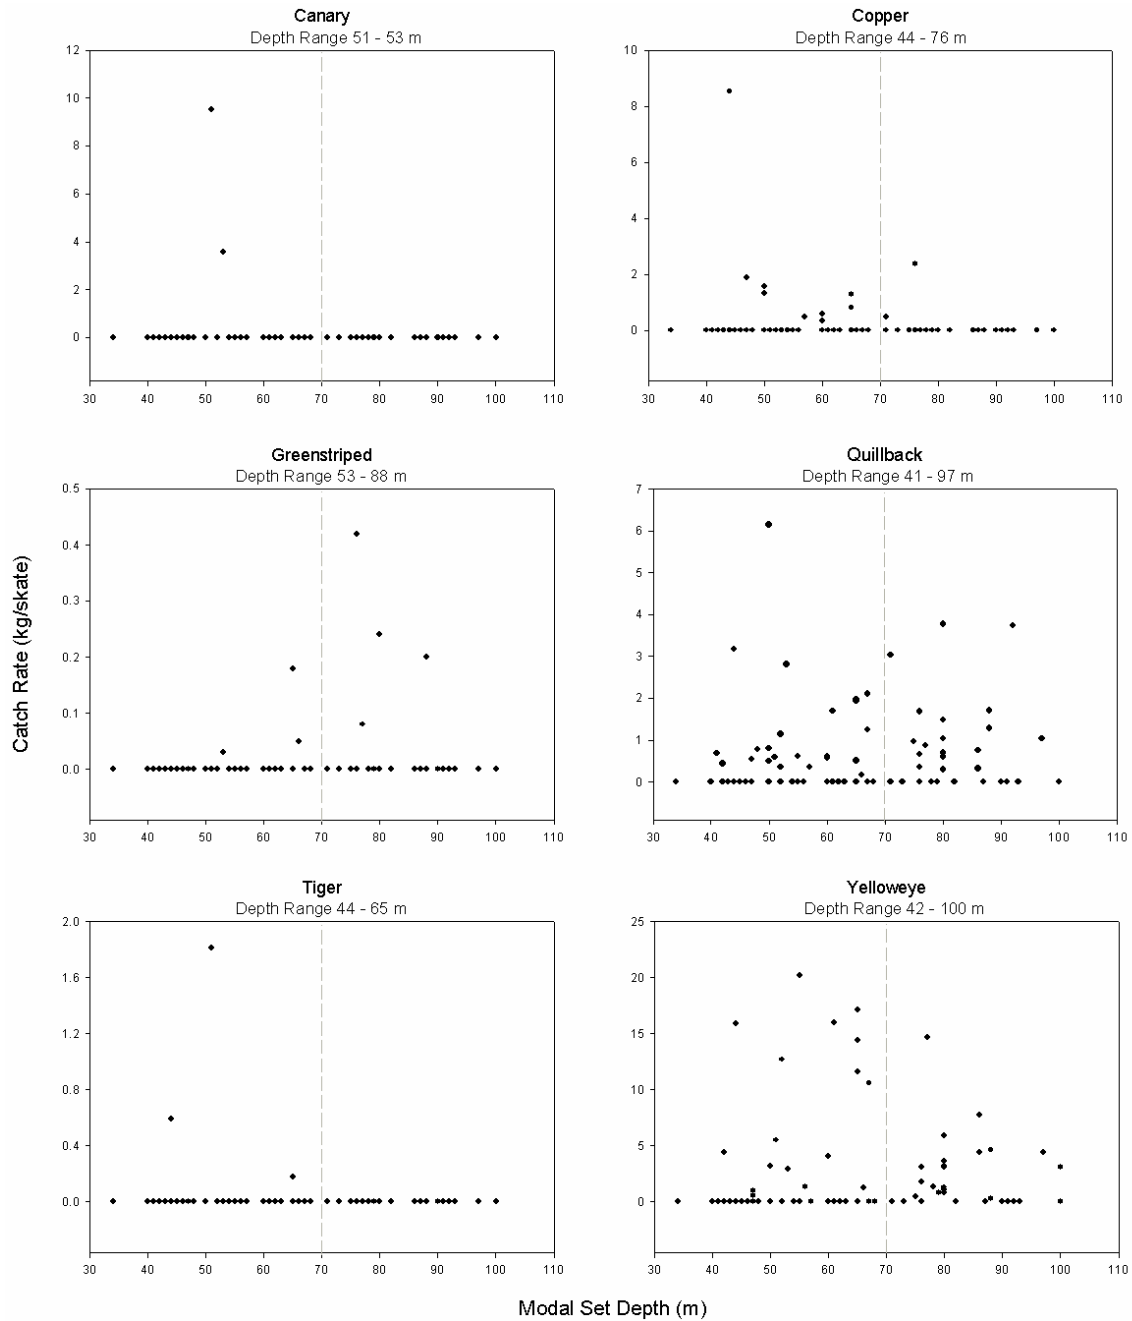

Figure 16. Relationships between catch rates (kg/skate) and modal set depth (m) for the six most frequently encountered rockfish on the survey. Depth ranges are for non-zero catch rates. The grey dotted line represents the boundary between the shallow stratum (41-70m) and the deep stratum (71-100m).

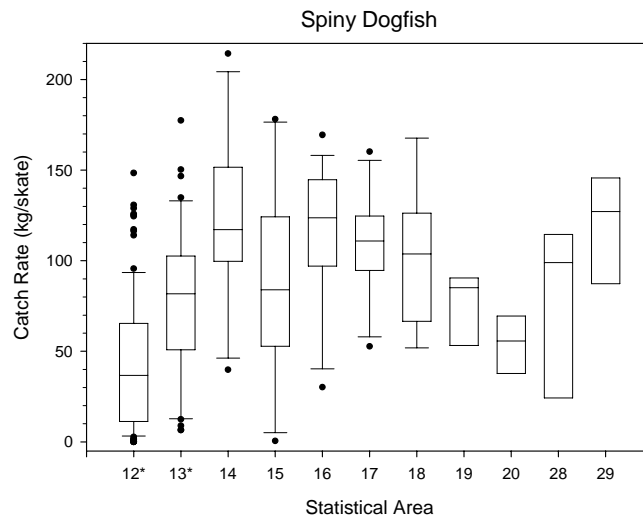

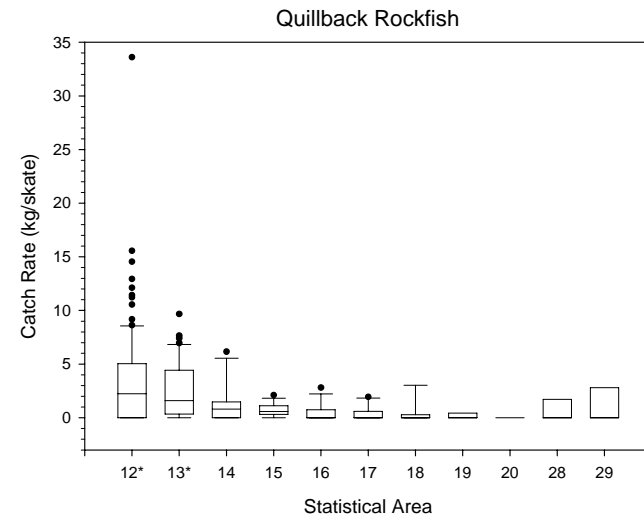

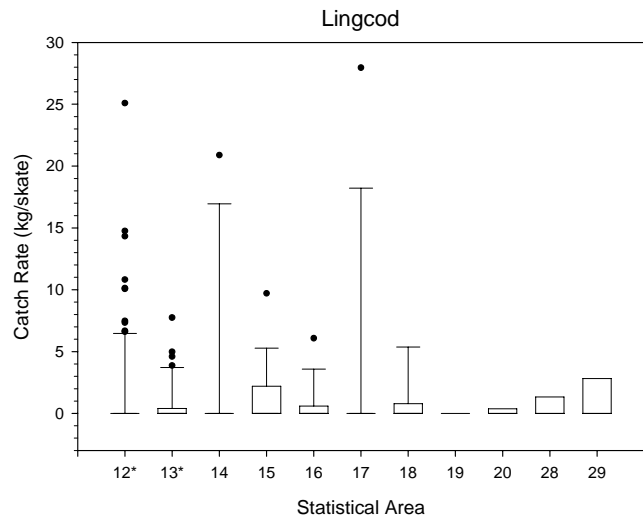

Figure 17. Lingcod, spiny dogfish, quillback and yelloweye rockfish catch rates (kg/skate) plotted by statistical area. \*Data for statistical areas 12 and 13 were collected in 2003 and 2004, and all other areas were surveyed in 2005.

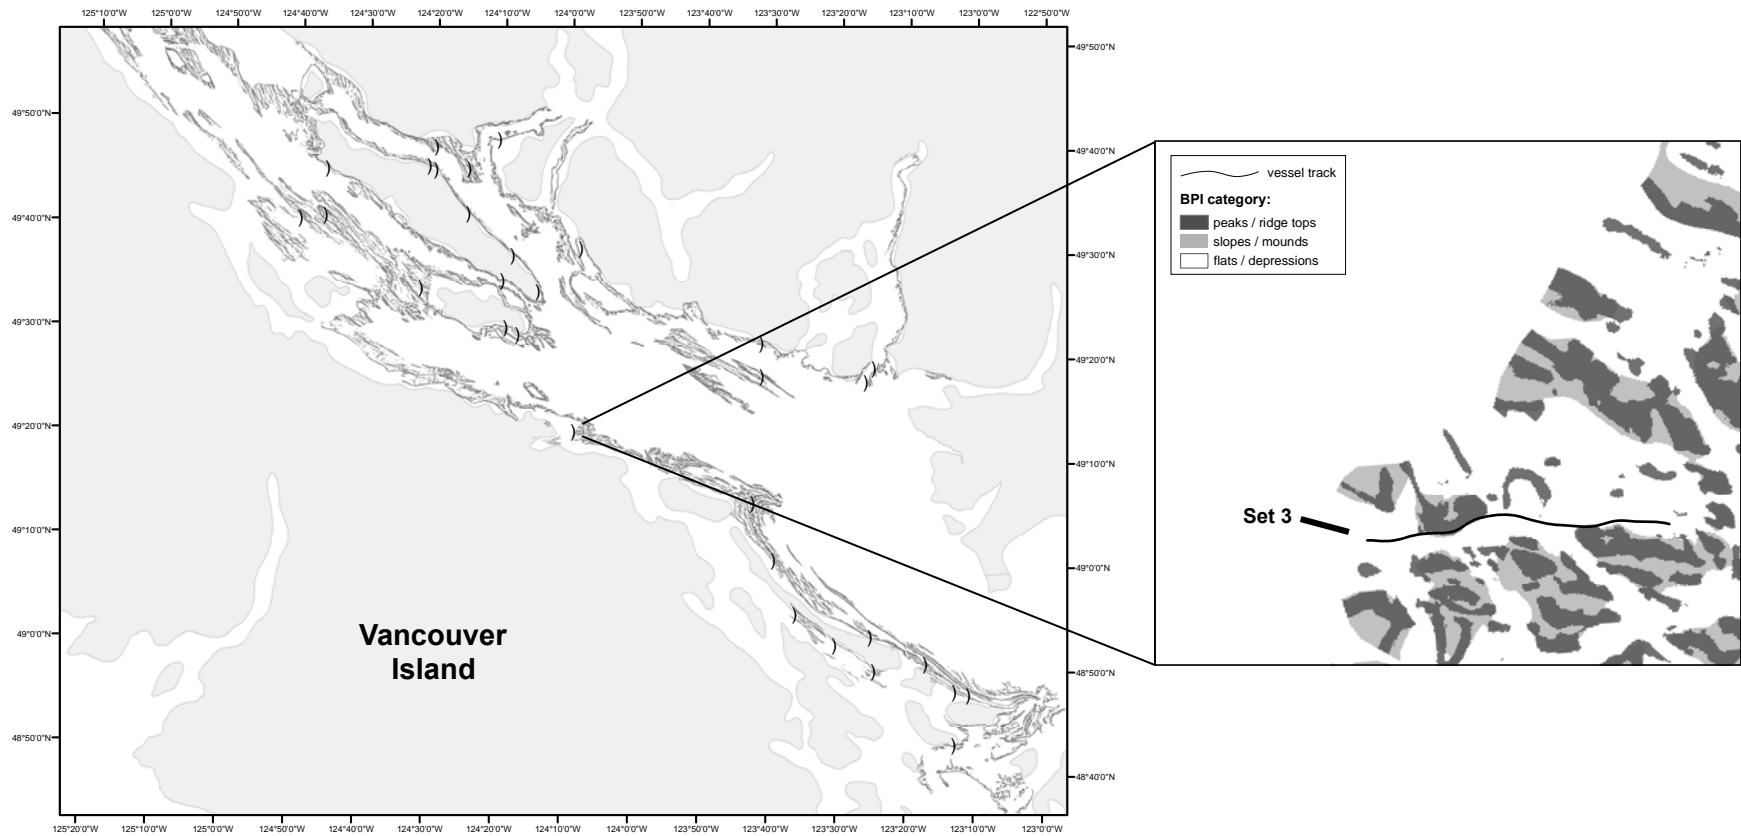

Figure 18. Location of the 31 survey blocks which were located in areas for which there was multibeam data and therefore included in the bathymetric position index analysis (left panel), and a close-up of one of the survey blocks (set 3) illustrating BPI categories and the vessel's track that was recorded during gear deployment (right panel).

Figure 19. Proportion of hooks that landed on each of the three bathymetric position index categories: flats / depressions, slopes / mounds, and peaks / ridge tops for hooks that yielded catch (i.e. not including empty hooks). The top panel illustrates proportions for prominent groundfish species and species groups, the bottom panel illustrates proportions for each rockfish species encountered on the survey, and ‘N’ indicates the number of fish observations.

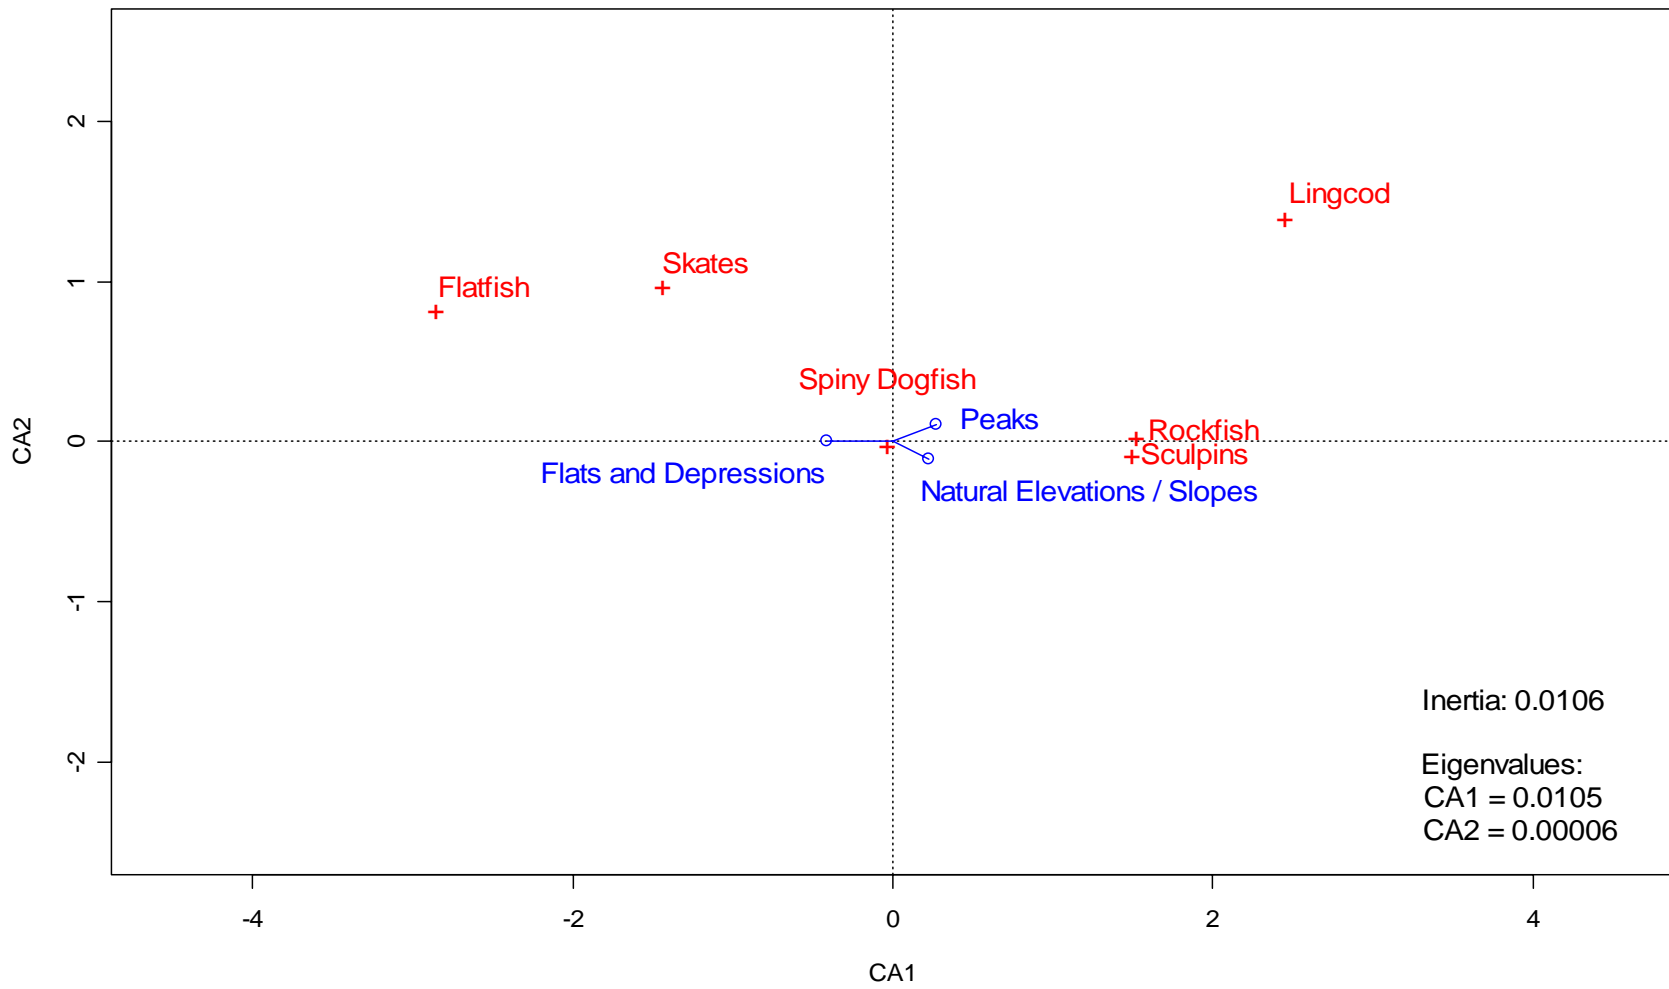

Figure 20. Correspondence analysis showing the relationship between species and species groups catch rates (#fish/hook) and bathymetric position index category.

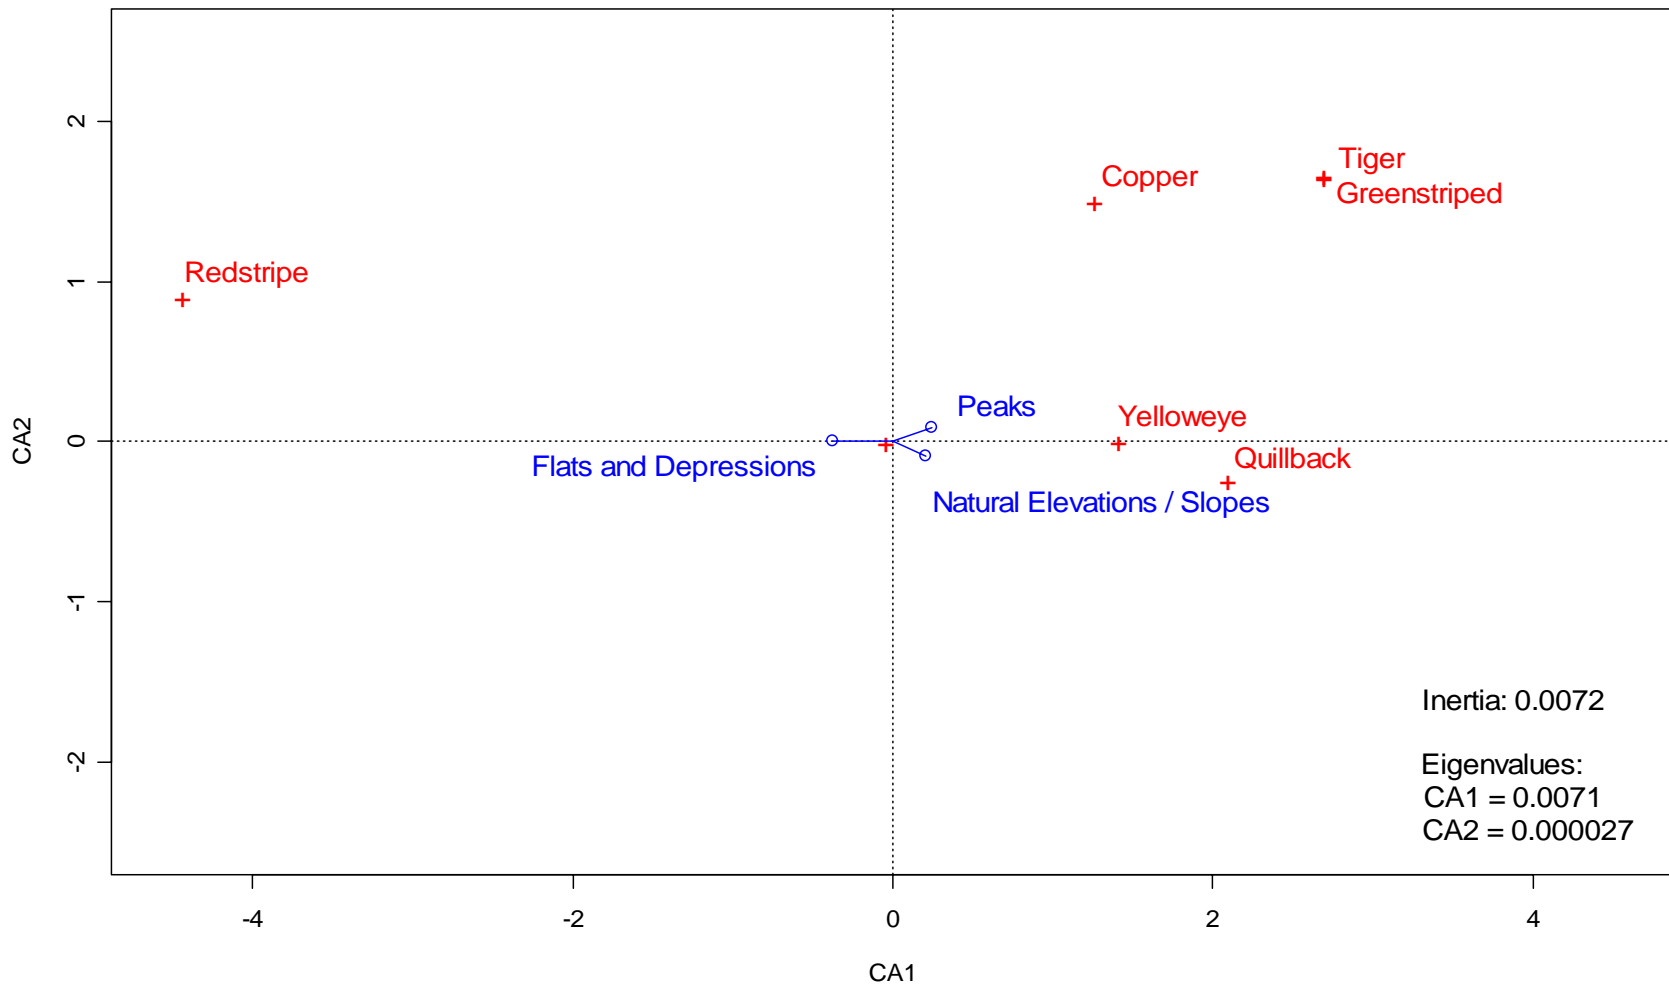

Figure 21. Correspondence analysis showing the relationship between rockfish species catch rates (#fish/hook) and bathymetric position index category.

Left Blank on Purpose

## Appendix B. Description of Beaufort scale sea state categories.

<b>Beaufort Scale</b>	<b>Description</b>
0	Calm, winds <1 knot, sea like mirror
1	Light air, winds 1 - 3 knots, ripples, no foam crests
2	Light breeze, winds 4 - 6 knots, small wavelets
3	Gentle breeze, winds 7 - 10 knots, crests breaking
4	Moderate breeze, winds 11 - 16 knots, whitecaps
5	Fresh breeze, winds 17 - 21 knots, moderate waves-spray
6	Strong breeze, winds 22 - 27 knots, large waves
7	Moderate gale, winds 28 - 33 knots, sea heaps up
8	Fresh gale, winds 34 - 40 knots, moderately high waves
9	Strong gale, winds 41 - 47 knots, high waves, spray
10	Whole gale, winds 48 - 55 knots, overhanging crests, sea white
11	Storm, winds 56 - 63 knots, exceptionally high waves
12	Hurricane, winds 64 - 118 knots, sea white
