Fisheries and Aquatic Sciences 3212**

Canadian Technical Report of Fisheries and Aquatic Sciences

Technical reports contain scientific and technical information that contributes to existing knowledge but which is not normally appropriate for primary literature. Technical reports are directed primarily toward a worldwide audience and have an international distribution. No restriction is placed on subject matter and the series reflects the broad interests and policies of Fisheries and Oceans Canada, namely, fisheries and aquatic sciences.

Technical reports may be cited as full publications. The correct citation appears above the abstract of each report. Each report is abstracted in the data base *Aquatic Sciences and Fisheries Abstracts*.

Technical reports are produced regionally but are numbered nationally. Requests for individual reports will be filled by the issuing establishment listed on the front cover and title page.

Numbers 1-456 in this series were issued as Technical Reports of the Fisheries Research Board of Canada. Numbers 457-714 were issued as Department of the Environment, Fisheries and Marine Service, Research and Development Directorate Technical Reports. Numbers 715-924 were issued as Department of Fisheries and Environment, Fisheries and Marine Service Technical Reports. The current series name was changed with report number 925.

Rapport technique canadien des sciences halieutiques et aquatiques

Les rapports techniques contiennent des renseignements scientifiques et techniques qui constituent une contribution aux connaissances actuelles, mais qui ne sont pas normalement appropriés pour la publication dans un journal scientifique. Les rapports techniques sont destinés essentiellement à un public international et ils sont distribués à cet échelon. Il n'y a aucune restriction quant au sujet; de fait, la série reflète la vaste gamme des intérêts et des politiques de Pêches et Océans Canada, c'est-à-dire les sciences halieutiques et aquatiques.

Les rapports techniques peuvent être cités comme des publications à part entière. Le titre exact figure au-dessus du résumé de chaque rapport. Les rapports techniques sont résumés dans la base de données *Résumés des sciences aquatiques et halieutiques*.

Les rapports techniques sont produits à l'échelon régional, mais numérotés à l'échelon national. Les demandes de rapports seront satisfaites par l'établissement auteur dont le nom figure sur la couverture et la page du titre.

Les numéros 1 à 456 de cette série ont été publiés à titre de Rapports techniques de l'Office des recherches sur les pêcheries du Canada. Les numéros 457 à 714 sont parus à titre de Rapports techniques de la Direction générale de la recherche et du développement, Service des pêches et de la mer, ministère de l'Environnement. Les numéros 715 à 924 ont été publiés à titre de Rapports techniques du Service des pêches et de la mer, ministère des Pêches et de l'Environnement. Le nom actuel de la série a été établi lors de la parution du numéro 925.

ABSTRACT

Beazley, L., Guijarro, J., Lirette, C., Wang, Z., and Kenchington, E. 2017. Characteristics of Environmental Data Layers for Use in Species Distribution Modelling in the Maritimes Region. *Can. Tech. Rep. Fish. Aquat. Sci.* 3212: vii + 327p.

Species distribution models (SDMs) are tools that combine species observations of occurrence, abundance, or biomass with environmental variables to predict the distribution of a species in unsampled locations. To produce accurate predictions of occurrence, abundance or biomass distribution, a wide range of physical and/or biological variables is desirable. Such data is often collected over limited or irregular spatial scales, and require the application of geospatial techniques to produce continuous environmental surfaces that can be used for modelling at all spatial scales. Here we provide a review of 102 environmental data layers that were compiled for the entire spatial extent of Fisheries and Oceans Canada's (DFO) Maritimes Region. Variables were obtained from a broad range of physical and biological data sources and spatially interpolated using geostatistical methods. For each variable we document the underlying data distribution, provide relevant diagnostics of the interpolation models and an assessment of model performance, and present the final standard error and interpolation surfaces. These layers have been archived in a common (raster) format at the Bedford Institute of Oceanography to facilitate future use. Based on the diagnostic summaries in this report, a subset of these variables has subsequently been used in species distribution models to predict the distribution of deep-water corals, sponges, and other significant benthic taxa in the Maritimes Region.

RÉSUMÉ

Beazley, L., Guijarro, J., Lirette, C., Wang, Z., et Kenchington, E. 2017. Characteristics of Environmental Data Layers for Use in Species Distribution Modelling in the Maritimes Region. Rapp. tech. can. sci. halieut. aquat. 3212 : vii + 327p.

Les modèles de répartition des espèces sont des outils qui rassemblent des observations d'espèces (occurrence, abondance ou biomasse) avec des variables environnementales pour prédire l'aire de répartition d'une espèce dans des emplacements non échantillonnés. Afin de produire des prévisions exactes de l'occurrence, de l'abondance ou de la répartition de la biomasse, il est souhaitable d'obtenir une vaste gamme de variables physiques ou biologiques (ou les deux). Ces données sont souvent recueillies sur des échelles spatiales limitées ou irrégulières et nécessitent l'application de techniques géospatiales pour produire des surfaces environnementales continues qui peuvent être utilisées pour la modélisation à toutes les échelles spatiales. Dans le présent document, nous offrons un examen de 102 couches de données environnementales qui ont été compilées pour l'ensemble de l'étendue spatiale de la région des Maritimes de Pêches et Océans Canada (MPO). Des variables ont été obtenues à partir d'une vaste gamme de sources de données physiques et biologiques interpolées sur le plan spatial à l'aide de méthodes géostatistiques. Pour chaque variable, nous documentons la répartition des données sous-jacentes, fournissons des analyses pertinentes des modèles de répartition et une évaluation du rendement des modèles. Nous présentons l'erreur type et les surfaces interpolées définitives. Ces couches de données ont été archivées dans un format commun (trame) à l'Institut océanographique de Bedford afin de simplifier leur utilisation future. En se fondant sur les résumés analytiques du présent rapport, un sous-ensemble de ces variables a par la suite été utilisé dans des modèles de répartition des espèces pour prévoir la répartition, en eau profonde, des coraux, des éponges et d'autres taxons benthiques importants dans la région des Maritimes.

INTRODUCTION

Species distribution modelling (SDM) is a tool that utilizes the relationship between a species and its environment in known (sampled) locations to predict the species' distribution in unsampled areas. SDM applications require continuous surfaces of each environmental predictor variable in order to predict across the spatial domain of the study extent to areas where environmental data do not exist. These variables are typically collected at different spatial and temporal resolutions, and are often spatially interpolated to provide continuous surfaces that can be used for predictive modelling at all spatial scales. Predictor variables may themselves be from direct measurements, modelled outputs, temporal averages, and derivations.

Continuous interpolated surfaces produced at high resolution often show very detailed spatial variation, implying that the surfaces are very precise. However, spatial interpolation methods are affected by sample size, sampling design and data quality properties, and variation within the data has very large impacts on the performance of the spatial interpolators (Li and Heap, 2008). There are over 60 methods to choose from, including geostatistical interpolators (e.g., kriging), non-geostatistical interpolators (e.g., inverse distance weighting, natural neighbours, nearest neighbours), and methods that combine both (Li and Heap, 2008).

The Scotian Shelf is a 700 km section of continental shelf off Nova Scotia that is bounded by the Laurentian Channel and Cabot Strait in the east and northeast, and the Gulf of Maine in the west. The shelf itself is broad, varying in width from 120 to 240 km, and is characterized by shallow offshore banks and deep basins, troughs, channels, and has a mean depth of ~116 m. Its steep slope is excised by a number of deep canyons and gullies. The oceanographic conditions on the Scotian Shelf and in Bay of Fundy are dynamic and vary seasonally and inter-annual, making broad characterization of this region difficult. Temperature and salinity conditions on the Scotian Shelf varies spatially due to its complex bottom topography, heat transfer between the ocean and atmosphere, inflow from the Gulf of St. Lawrence and Newfoundland Shelf, exchange with offshore slope waters, local mixing, freshwater runoff, direct precipitation, and melting of sea ice in the spring (Drinkwater et al., 2003; Hebert et al., 2013). The dynamicity of this region highlights the importance of including frequent and long-term time series data to describe mean oceanographic climate.

Here, we provide detailed information on 102 environmental data layers collected over different spatial and temporal resolutions and spatially interpolated using the ordinary kriging method to provide continuous surfaces across the entire domain of Fisheries and Oceans Canada's (DFO) Maritimes Region. For each variable, we show the distributional properties of the raw data prior to spatial interpolation, model performance indicators and assessment of model performance, and finally, maps of the prediction standard error and interpolation prediction surfaces. Our intention is that these variables are used in species distribution modelling or other ecosystem-based management applications. A subset of these variables have already been used in random forest and generalized additive models to predict the probability of occurrence and biomass distribution of deep-water corals, sponges, and other significant benthic taxa (see Beazley et al., 2016a; 2017), the results of which are currently being used to identify important areas in conservation planning applications.

MATERIALS AND METHODS

Study Area

Fisheries and Oceans Canada's (DFO) Maritimes Region, one of DFO's six administrative regions across Canada, was used as the spatial boundary for the construction of environmental variables in this report (Figure 1). This study area encompasses the Bay of Fundy, part of the Laurentian Channel and Cabot Strait, and the entire Scotian Shelf, Slope, Rise, and Abyssal Plain. The extent is delimited by the Canadian Maritime Boundary to the west in Gulf of Maine, the 200 nautical mile Exclusive Economic Zone (EEZ) in the south, the Placentia Bay-Grand Bank Large Ocean Management Area in the east, and the Gulf Region MPA Network Planning Boundary in the north. A 5 kilometre buffer was added around all land points.

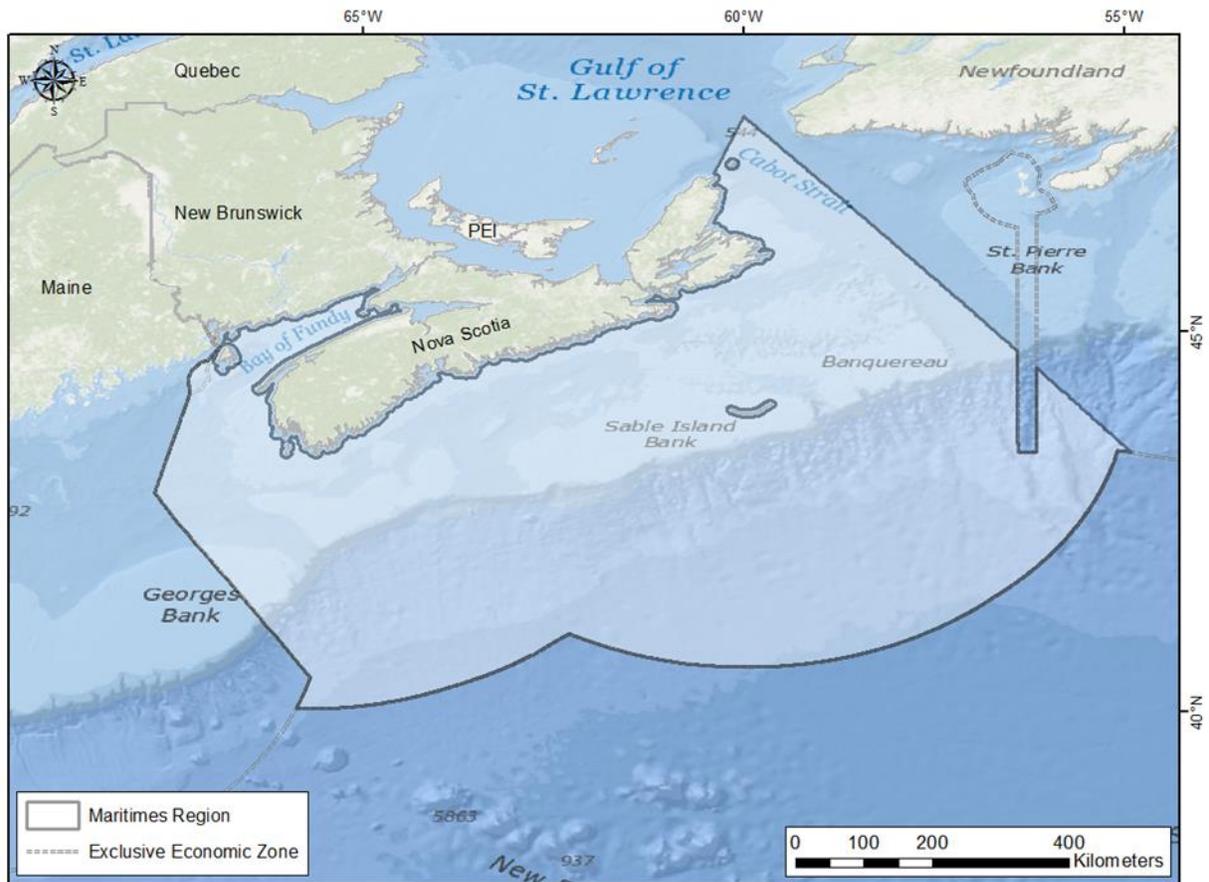

Fig. 1. Extent of the DFO Maritimes Region boundary used for creating interpolated surfaces of environmental variables.

Data Sources

Global Ocean Reanalyses and Simulations (GLORYS)

Data for surface and bottom temperature, salinity, current speed, bottom shear, and mixed layer depth were extracted from the Global Ocean Reanalyses and Simulations (GLORYS2V1). GLORYS2V1 is a numerical ocean general circulation model reanalysis product with $\frac{1}{4}^\circ$ horizontal resolution (approximately 20.4 km in the Maritimes Region; Fig. 2) that aims to provide the mean and time-varying state of the oceanic states with a focus on capturing variation of meso-scale eddies (<http://www.mercator-ocean.fr/eng/science/GLORYS>). Details on this model and its caveats can be found in Beazley et al. (2016b).

For each variable, two different sets of statistics were created from the GLORYS2V1 monthly data. First, the absolute minima, maxima, and range were calculated for each variable by taking the minimum and maximum values across all months and years at each location. Range was calculated as the difference between these values at each location. In this report these variables are denoted as Minimum/Maximum/Range. These ‘absolute’ variables are likely reflective of anomalous events over the time period. The second dataset was created by calculating the average minima, maximum and range by taking the minimum and maximum values at each location across all months within a year, and averaging across years. These variables are denoted as Average Minimum/Maximum/Range in this report, and are likely more representative of long-

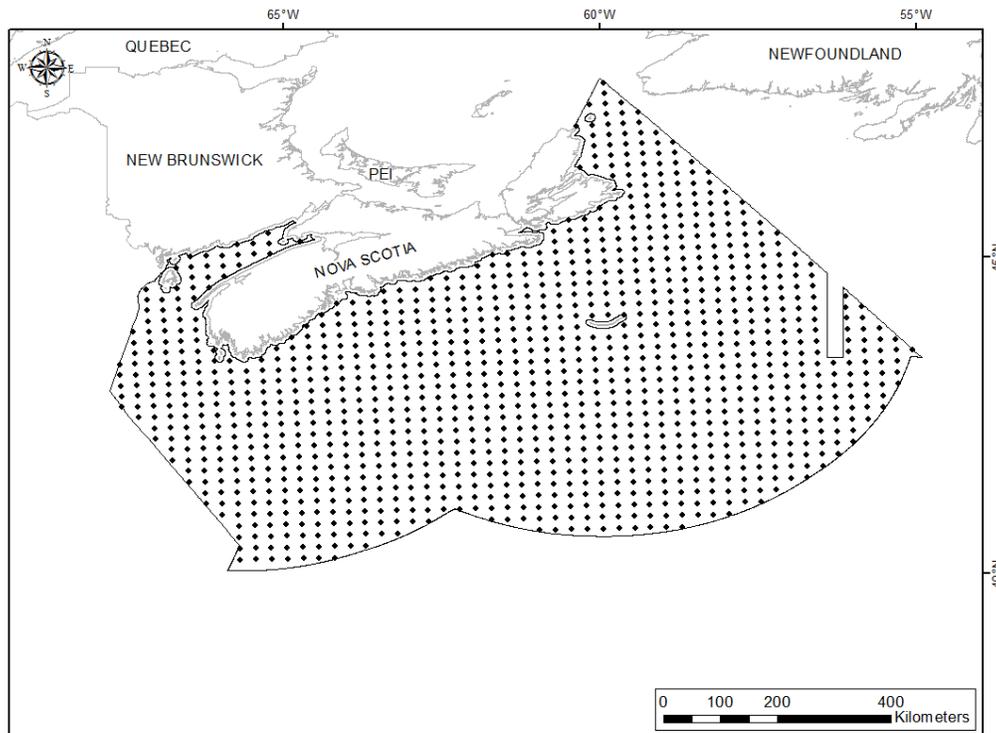

Fig. 2. Distribution of point data extracted from the GLORYS2V1 model from 1993 to 2011 for the Maritimes Region. Point data have a native resolution of $\frac{1}{4}^\circ$ (~20.4 km).

term oceanographic conditions in the region. Finally, the mean of each variable was calculated by averaging the values at each location across all months and years, and is denoted as the Mean in this report. For mixed layer depth, statistics were compiled quarterly to derive spring (April - June), summer (July - September), fall (October - December) and winter (January - March) variables. Zero values in the current and shear data, which were falsely generated from a model topography issue, were removed prior to calculating the statistics.

Sea Surface Chlorophyll *a*

Sea surface chlorophyll *a* data were derived from Aqua-MODIS (Moderate Resolution Imaging Spectroradiometer) Case I was processed by the Remote Sensing Unit at the Bedford Institute of Oceanography (RSU-BIO). In deep oceanic waters, optical properties are dominated by phytoplankton and the observed spectral features in the reflected light can be directly related to chlorophyll *a* concentration (Moses et al., 2009). These waters are referred to as Case I waters. In Case I waters, spectral algorithms that use reflectances in the blue green regions of the spectrum have shown to accurately estimate chl-*a* concentration. In contrast, most inland, estuarine, and coastal waters that are rich in suspended solids and dissolved organic matter are referred to as Case II waters. The optical properties of Case II waters are therefore not dominated by phytoplankton, and spectral algorithms based on reflectance in the red and near-infrared spectral regions are typically used to estimate chl-*a* concentration (Moses et al., 2009). Generally, Case I chlorophyll calculations should not be used for Case II waters. In the Maritimes Region, the Bay of Fundy is considered Case II waters due to its strong tidally-induced vertical mixing and resuspension of organic material (Harrison et al., 2007). A comparison of satellite-derived chlorophyll *a* to *in situ* measurements in Bay of Fundy revealed significant over-estimation of chlorophyll concentration by both MODIS Case I and MERIS Case II algorithms, although Case II was closer than Case I. Coastal waters less than 30 m deep are also considered Case II, however, these waters are generally excluded in our study due to the 5-km land buffer applied to land values. Given that the majority of the Maritimes Region is considered Case I, we therefore opted to include only MODIS Case I chlorophyll *a* data layers in this report but acknowledge that this algorithm does not adequately represent chlorophyll *a* concentration in Bay of Fundy.

Daily MODIS (Aqua Level-2) data from 2002 to 2012 were downloaded from NASA's OceanColor Web (<http://oceandata.sci.gsfc.nasa.gov/>). Composite images were displayed in raster format with a resolution of 2 km. Data from 2003 to 2011 were used. Individual passes were filtered to eliminate extreme outliers using the median of a 3 x 3 pixel matrix (ENVI-IDL). The native resolution of the point data for MODIS Case I chlorophyll *a* data is shown in Fig. 3.

Annual and seasonal averages were computed for the MODIS Case I dataset. Seasons were delimited by the following 'day of year' ranges: days 91 – 181 (spring), 182 – 273 (summer), and 274 – 365 (fall). These seasonal delimitations capture the peak of the spring and fall phytoplankton blooms over most of the Scotian Shelf. Alternate seasonal ranges could be considered that would fully capture the spring phytoplankton bloom in all areas of the study extent. The minimum, maximum and range values for each season (except winter) and annually were derived from these using the 'Cell Statistics' tool in ArcMap's Spatial Analyst toolbox. Zero and N/A values in the chlorophyll data were removed prior to calculating the statistics.

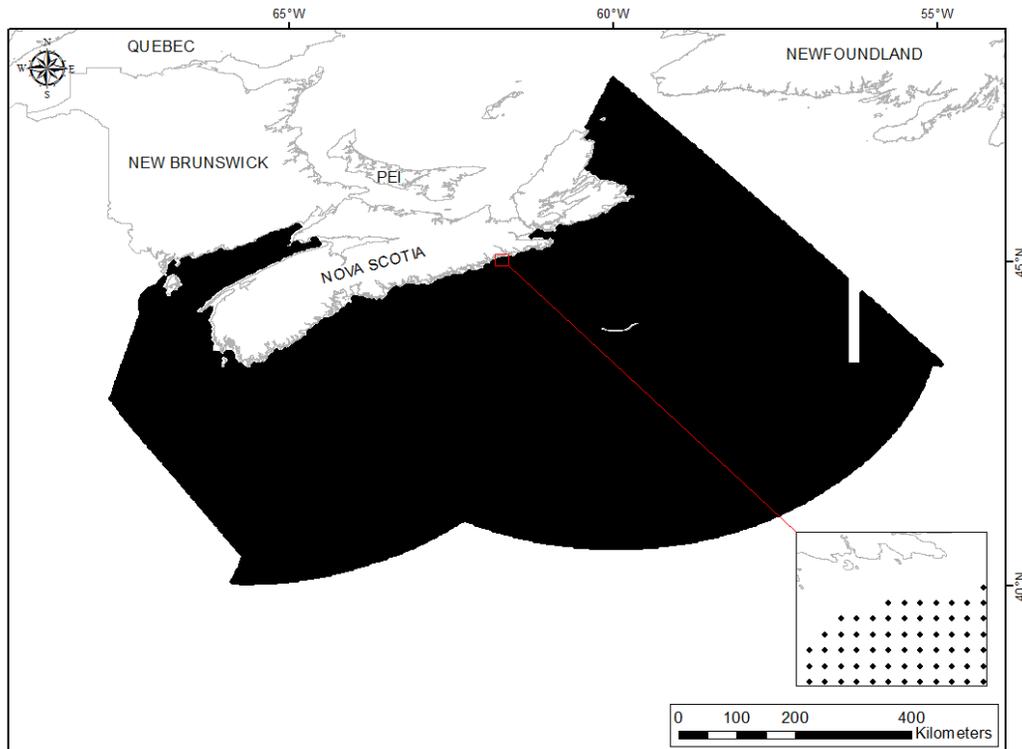

Fig. 3. Distribution of sea surface chlorophyll *a* (MODIS Case I) point data (spring, summer, fall and annual) for the Maritimes Region. Point data have a native resolution of 2 km.

Sea Surface Primary Production

Primary production was calculated following the method of Platt et al. (2008) using software developed by the RSU-BIO and the Department of Oceanography at Dalhousie University. The calculation of primary production requires input from multiple sources. Monthly mean surface chlorophyll *a* and photosynthetically active radiation (PAR) was obtained from NASA's Sea-viewing Field-of-view Sensor (SeaWiFS) Level 3, 9-km global coverage (reprocessing R2010.0; Feldman and McClain, 2012). Sea surface temperature (SST) was obtained from NOAA Pathfinder version 5.2 data and was reprocessed from its native resolution of 4000 m² pixel⁻¹ to match the spatial and temporal resolution of chlorophyll data. Monthly images of total cloud fraction data used in the model were obtained in November 2014 from MYD08_M3, a monthly aggregation of MYD35, collection 51 (ftp://ladsweb.nascom.nasa.gov/allData/51/MYD08_M3/). The *in situ* parameters, such as photosynthetic performance, chlorophyll *a*, sea surface temperature, and water depth originate from ship-based observations made by DFO's Atlantic Zone Monitoring Program (AZMP; <http://www.bio.gc.ca/science/monitoring-monitorage/azmp-pmza-en.php>). Reliability of the resulting primary production data is therefore unknown for areas outside the AZMP region. The model described in Platt et al. (2008) results in pixel-by-pixel depth-integrated net primary production (mg C m⁻² day⁻¹) calculated for the 15 day of each month from September 2006 to September 2010. Like the GLORYS2V1-derived variables, monthly values for primary production allowed for the calculation of both 'absolute' and 'average' minima, maxima, and range quantifications. However, for some months and years no

data was available (see Table 1), therefore only spring (April – June), summer (July – Sept.), fall (October to December) and annual layers were created. For the creation of these variables, we ensured that each point location across the study extent had at least two months of data in each of the five years contributing to the quantifications. Spring, summer and annual surfaces showed nearly full coverage across the Maritimes Region, whereas large areas off Cape Breton, southwest Nova Scotia and Bay of Fundy are not covered in the fall as these are locations with less than one month of data contributing across the 5-year data period.

Table 1. Contributing months to each of the 5 years of data for the primary production dataset. The √ indicates that data exists for this month. Note however that even though data exists for a particular month, each point location across the Maritimes Region study extent may not have observation data.

World Ocean Database 2013 (WOD13)

Dissolved oxygen and nutrients (nitrate, phosphate, and silicate) were extracted from the World Ocean Database 2013 (WOD13) (<https://www.nodc.noaa.gov/OC5/WOD13/>; Boyer et al., 2013) produced by the US National Oceanographic Data Center (NODC) Ocean Climate Laboratory (OCL). WOD13 houses ocean profile and plankton measurement data submitted by individual scientists and institutional, national, and regional data centres with the goal of providing a centralized source for large-scale oceanographic data and metadata that has been formatted in a similar way. Data in WOD13 are organized under four different operational definitions: profile, cast, station, and cruise. Each data value and profile in WOD13 are associated with their own quality control flag. Data collected in a similar manner are further grouped together into 11 different datasets.

The data were queried from the WODselect retrieval system (<https://www.nodc.noaa.gov/OC5/SELECT/dbsearch/dbsearch.html>) using user-specified search

criteria under the following four categories: geographic coordinates, observation dates, dataset, and measured variables. Nutrient data were queried from the Ocean Station Data (OSD) dataset from the period of 2006 to 2011, which corresponded to the start of when the highest quality control indicators accompanied the data, and end period of the GLORYS data layers. In the event where more than one value was measured at a single location, the data values were averaged. The OSD dataset groups together bottle (Nansen and Niskin) and bucket data, plankton data, and low resolution CTD and expendable CTD (XCTD) data, and is the only dataset in WOD13 that contains nutrient data. Only data collected within the top 10 metres of water and with the highest quality control flag ('Accepted') were used. Only dissolved oxygen showed good enough coverage over the Maritimes Region to spatially interpolate the data (see Fig. 5).

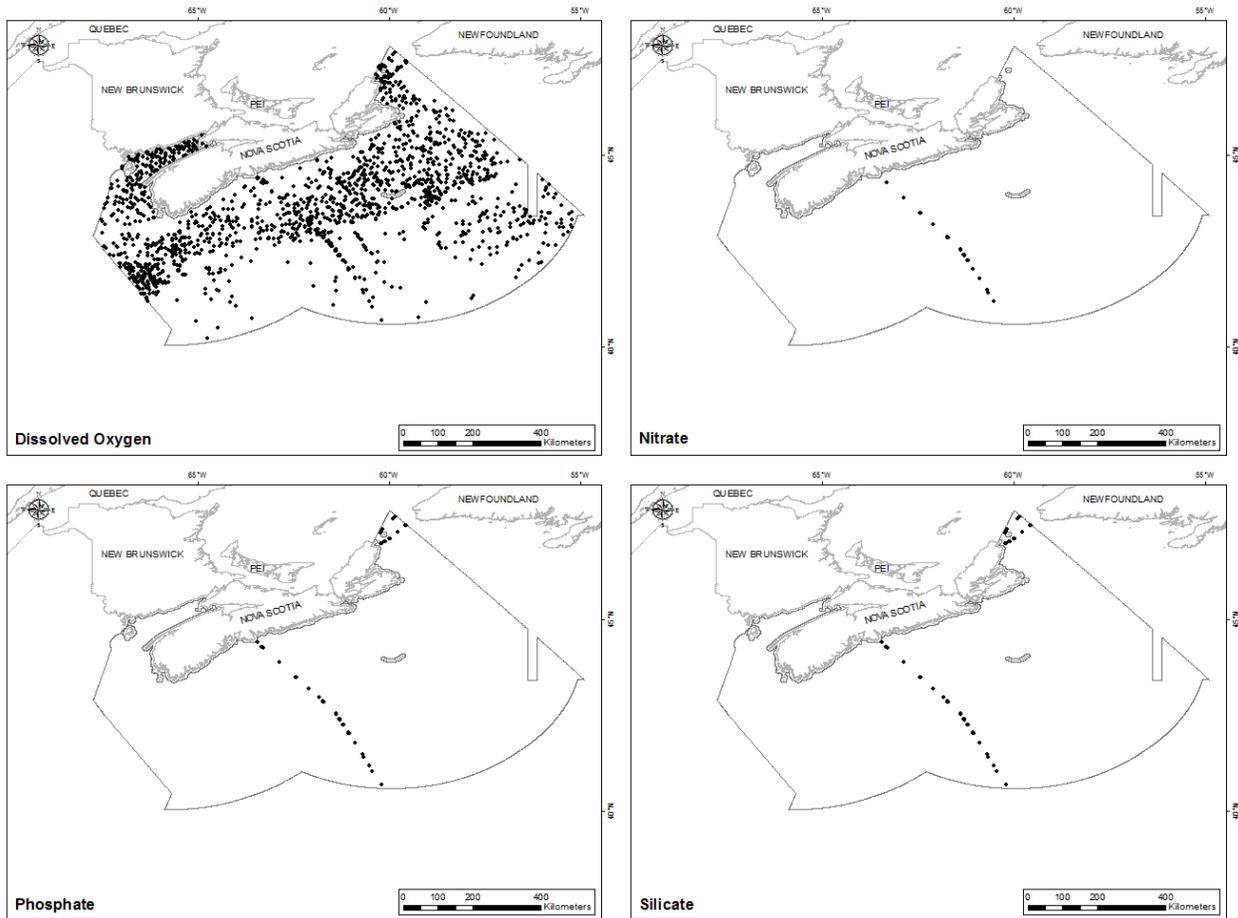

Fig. 5. Distribution of dissolved oxygen, nitrate, phosphate, and silicate point data from 2006 to 2011 extracted from WOD13 for the Maritimes Region. The spatial distribution of the data is not uniform across the study extent.

Spatial Interpolation Methods

Data Exploration and Model Fitting (adapted from Beazley et al., 2016b)

Kriging is a family of geostatistical estimators used to interpolate spatial data. It is a generalized least-square regression technique that allows for spatial prediction in unsampled locations by accounting for the spatial dependence between observed data (Goovaerts, 2000). Spatial dependence is captured by constructing an empirical semivariogram that shows the average semivariance between points by the distance between them. A semivariogram model is then fit to the points forming the empirical semivariogram, and predictions are generated for unmeasured locations based on a weighted average of neighbouring data and their spatial arrangement (Johnston et al., 2001).

Within the kriging family a number of different methods exist including but not limited to, ordinary kriging, universal kriging, and simple kriging. For this report, we chose ordinary kriging as the method of spatial interpolation as it assumes that the mean is unknown prior to modelling and approximately constant (stationary) only in the local neighbourhood of each estimation point and not over the entire data domain (Li and Heap, 2008; Krivoruchko, 2011). Thus ordinary kriging with a local search neighbourhood already accounts for trends in the data (Li and Heap, 2008). When compared against the Inverse Distance Weighting (IDW) interpolation method, ordinary kriging produced better overall mean prediction and root-mean-square errors and smoother prediction surfaces for the same variables interpolated in the Gulf Region (see Beazley et al., 2016b).

Ordinary kriging as a geostatistical interpolator does not require the data to follow a normal distribution (Krivoruchko, 2011). However, the generation of quantile and probability maps using ordinary kriging does require the data to meet this assumption (Krivoruchko, 2011). Transformation of highly skewed data prior to ordinary kriging may result in improved estimates and prediction errors, particularly if the dataset is small and contains outliers (Kravchenko and Bullock, 1999). If a variable shows positive skewness, the confidence limits on the variogram are wider than normal resulting in higher variance (Robinson and Metternicht, 2006; Yamamoto, 2007). Thus, data are often transformed prior to spatial interpolation in order to improve the calculation of statistics and weighted averages (Yamamoto, 2007). Transformation of the data results in estimates on a different scale than the original data, and so it is necessary to back-transform the kriging estimates to their original scale prior to creating the interpolation surface. However, for logarithmic transformation, back-transformation through exponentiation results in exaggerated interpolation-related errors, with extreme errors being the worst affected (Goovaerts, 1997; Robinson and Metternicht, 2006). In the Maritimes Region, variables that had been back-transformed within the Geostatistical Analyst package had poorer prediction errors when compared to variables that were log-transformed outside the ArcMap forum (and thus, were not back-transformed in ArcMap). Therefore, to avoid biased prediction errors, we chose not to transform our data prior to spatial interpolation.

Prior to interpolation we assessed the distributional properties of all variables by examining histograms and summary statistics generated in the 'Explore Data' option in ArcMap's

Geostatistical Analyst package. These were reviewed to detect anomalous data points and to visually assess departures from a normal distribution (skewness, kurtosis) in advance of conducting geostatistics. Data distributions were described in terms of their skew (right, or positive, and left, or negative), and kurtosis. Kurtosis is a measure of the ‘tailedness’ of the distribution, where values equal to 3 are considered mesokurtic (zero tailedness), values < 3 platykurtic (thin-tailed), and values > 3 are leptokurtic (heavy-tailed) (DeCarlo, 1997). Normal Q-Q plots were then constructed to compare the distribution of the data against a standard normal (Gaussian) distribution. The data values are ordered and cumulative distribution values are calculated as $(i - 0.5)/n$ for the i^{th} ordered value out of n total values. If the data values are normally distributed they will form a perfect line at 45° to the origin. Data values that fell above and below the reference line were mapped to identify any spatial trend in the departure from normality.

Ordinary kriging models were created using all default settings in the Geostatistical Analyst wizard. Default settings are a stable semivariogram model type and a circular search neighbourhood with 4 sectors that capture a minimum of 2 and a maximum of 5 neighbours. The optimization function was set for each model, which determines the optimal partial sill, nugget, lag size, and number of lags based on the model range.

Caveat for Spatial Interpolation Using Ordinary Kriging

We noted that ordinary kriging of some GLORYS and chlorophyll *a* ‘range’ variables resulted in negative values in the prediction surfaces. This is in addition to some of the small negative values produced by the GLORYS model itself (see Beazley et al., 2016b for description). In the Maritimes Region this phenomenon occurred in the following variables:

1. Bottom Salinity Range
2. Bottom Salinity Average Range
3. Bottom Temperature Range
4. Bottom Temperature Average Range
5. Spring Chlorophyll *a* Range
6. Annual Chlorophyll *a* Range

This issue has been previously described by Deutsch (1996) and Ly et al. (2011), who found that negative weights were generated by ordinary kriging models when outlying data points occurred close to the location being estimated. Ly et al. (2011) suggested two methods for dealing with this issue: 1) apply an *a posteriori* correction as outlined in Deutsch (1996), or 2) to replace all negative interpolated values with zero. To determine the influence of these variables with negative values on a species distribution model, we ran several random forest models with these variables as-is (i.e. with the negative interpolated values), and models with the negative values changed to zero. We found very little difference in the resulting surfaces and accuracy measures between models run with the negative values and those negative values changed to zero (see Guijarro et al., 2016). We conclude that these negative values have a negligible impact on species distribution modelling applications. The location of negative values in the prediction surface of each variable are shown in Appendix I.

Assessment of Model Performance (extracted from Beazley et al., 2016b)

Model performance was examined by performing cross-validation, a process where each data point is removed in turn from the model and predicted by the remaining data points. Geostatistical Analyst provides several graphical summaries of the cross validation results, including a scatterplot of the measured versus predicted values (called the Prediction plot), a scatterplot of the residuals of the measured values versus the predicted values (Error plot), a standardized error plot, which shows measured values subtracted from the predicted values and divided by the estimated kriging standard errors, and finally a Q-Q plot, which shows the quantiles of the difference between the predicted and measured values and the corresponding quantiles from a standard normal distribution to assess the normality of the error distributions. Of these, we show only the Prediction plot in the report, although all plots were visually assessed. In the Prediction plot, a horizontal relationship indicates that the model has no information content. With autocorrelation and a good geostatistical model, the relationship between the measured and predicted values should be 1:1.

Also provided by cross validation are five prediction error statistics used for performance evaluation (see Table 2). The overall mean error represents the difference between the measured and predicted values, and should be near zero if the prediction errors are unbiased (i.e., centred on the measured values). However, this value depends on the scale and units of the data, therefore it is better to assess the standardized prediction errors, which are given as prediction errors divided by their prediction standard errors. The mean (Standardized Mean) of these should also be near zero. If the Average Standard Error is close to the Root-Mean-Square Prediction Error, variability in the predictions has been correctly assessed. The Standardized Root-Mean-Square error should be close to one. If the Average Standard Error is greater than the Root-Mean-Square Prediction Error, or if the Standardized Root-Mean-Square Prediction Error is less than one, then the variability of predictions has been overestimated. If the Average Standard Error is less than the Root-Mean-Square Prediction Error or if the Standardized Root-Mean-Square Prediction Error is greater than one, then the variability of predictions has been

Table 2. Prediction error statistics rules used to assess performance of ordinary kriging models.

Prediction error	Rule
Overall Mean Error	Close to 0
Root-Mean-Square Prediction Error	Close to 0 and approximately equal to the average standard error
Standardized Mean	Close to 0
Standardized Root-Mean-Square Prediction Error	Close to 1
Average Standard Error	Approximately equal to the root mean square prediction error

underestimated. In summary, a good geostatistical model has an Overall Mean Error and Standardized Mean near zero, a small Root-Mean-Square Prediction Error that is approximately equal to the Average Standard Error, an Average Standard Error approximately equal to the Root-Mean-Square Prediction Error, and a Standardized Root-Mean-Square Prediction Error close to one (Johnston et al., 2001). These five prediction error statistics are provided for each variable and are assessed against the rules in Table 2 to provide an overall assessment of model performance.

Finally, model performance was assessed through visual examination of a standard error map. A standard error map quantifies the uncertainty of the prediction and is calculated by taking the square root of the kriging variances. If the data comes from a normal distribution, the true value will be within ± 2 times the prediction standard errors about 95% of the time (Johnston et al. 2001). These maps were used to determine whether there was any spatial pattern in the error distribution.

During the assessment of model performance, we noted that data with a poor underlying distribution did not always result in poor cross validation statistics during the interpolation process. For instance, ordinary kriging on some variables displaying a bimodal distribution (e.g., Bottom Temperature Mean in Beazley et al. 2016b) produced a good fit between measured and predicted values and good to excellent cross validation statistics, suggesting the ordinary kriging is robust to non-normality. Similarly, a model displaying a good fit between measured and predicted values often showed poor cross validation statistics, particularly a higher-than-expected Standardized Root-Mean-Square Prediction Error, indicating that variability in the predictions has been underestimated.

RESULTS

Temperature

Both surface and bottom temperatures have biological relevance to benthic invertebrates. Temperature directly influences the rates of activities associated with feeding such as pumping, filtration and digestion, movement, and growth. Temperature can also influence larval duration and timing of metamorphosis (Vance, 1973). Surface water temperature can influence primary and secondary production and hence benthic food supply. Temperature, along with salinity, can be used to indicate water mass structure.

Bottom Temperature Mean

This variable displayed a slightly right-skewed, platykurtic distribution prior to interpolation (Table 3, Fig. 6). The data were greater than predicted by a normal distribution at the smallest values and upper mid-values and less than predicted at the highest and mid-values (Fig. 7). These areas of under- and over-prediction showed spatial pattern over the region (Fig. 7).

The semivariogram showed moderate autocorrelation present in the data (Fig. 8). The kriged model showed a good fit between measured and predicted value and good cross-validation statistics (Table 4), indicating it was good at prediction despite the distribution of the underlying data. The error map showed high error along the edges of the study extent (Fig. 9). The kriged surface is presented in Fig. 10.

Bottom Temperature Minimum

This variable displayed a right-skewed, leptokurtic distribution prior to interpolation (Table 5, Fig. 11). The data were greater than predicted by a normal distribution at the smallest and upper-mid-values and less than predicted at the highest and mid values (Fig. 12). These data points were somewhat spatially cohesive with specific areas of over- and under-prediction (Fig 12).

The semivariogram showed weak autocorrelation present in the data (Fig. 13). The kriged model showed a good fit between measured and predicted values (Fig. 13) and good cross-validation statistics (Table 6), indicating it was good at prediction. The error map showed high error along the edges of the study extent (Fig. 14). The kriged surface is presented in Fig. 15.

Bottom Temperature Maximum

This variable displayed a right-skewed, platykurtic and bimodal distribution prior to interpolation (Table 7, Fig. 16). The data were greater than predicted by a normal distribution at low and upper mid-values while the mid-range values of the data were under-predicted (Fig. 17). These data points were somewhat spatially cohesive with specific areas of over- and under-prediction (Fig. 17).

The semivariogram showed autocorrelation present in the data (Fig. 18). The model showed a good fit between measured and predicted values (Fig. 18). Good performance of the model was indicated by the cross-validation results (Table 8). The error map showed high error along the edges of the study extent (Fig. 19). The kriged surface is presented in Fig. 20.

Bottom Temperature Range

This variable displayed a right-skewed distribution prior to interpolation (Table 9, Fig. 21). At both of the tails the actual data were greater than predicted by a normal distribution while there was an area of under-prediction at mid-range values (Fig. 22). These areas of under- and over-prediction showed spatial pattern over the region (Fig. 22).

The semivariogram showed moderate autocorrelation present in the data (Fig. 23). The kriged model showed a good fit between measured and predicted values (Fig. 23) and good cross-validation statistics (Table 10), indicating it was good at prediction. The error map showed high error along the edges of the study extent (Fig. 24). The kriged surface is presented in Fig. 25. Negative values resulted from the right-skewed nature of the raw data (Fig. 21). Of the 326,283 raster cells in the study extent, 1,970 contained negative values (see Table A1). These were located in a long band along the lower slope (Fig. A1).

Bottom Temperature Average Minimum

This variable displayed a right-skewed, leptokurtic distribution prior to interpolation (Table 11, Fig. 26). The data were lower than predicted by a standard normal distribution in the highest and mid-range values and higher than predicted at low values and in the upper mid-data range (Fig. 27). These areas of under- and over-prediction showed some spatial pattern over the region (Fig. 27).

The semivariogram showed weak autocorrelation present in the data (Fig. 28). The model showed a good fit between measured and predicted values (Fig. 28). Good performance of the model was also indicated in the good cross-validation statistics (Table 12). The error map showed high error along the edges of the study extent (Fig. 29). The kriged surface is presented in Fig. 30.

Bottom Temperature Average Maximum

This variable displayed a right-skewed, platykurtic distribution with outlying data in the upper range (Table 13, Fig. 31). The data were higher than predicted by a normal distribution at the tails of the distribution and under-predicted through the lower mid-range of the data (Fig. 32). These data points were somewhat spatially cohesive with specific areas of over- and under-prediction (Fig. 32).

The semivariogram showed moderate autocorrelation present in the data, and the model showed a good fit between measured and predicted values (Fig. 33). Good performance of the model was indicated by the good cross-validation statistics (Table 14). The error map showed high error along the edges of the study extent (Fig. 34). The kriged surface is presented in Fig. 35.

Surface Temperature Mean

This variable displayed a right-skewed, platykurtic distribution prior to interpolation (Table 17, Fig. 41). The data were higher than predicted by a standard normal distribution at low and upper mid-range values and lower than predicted at the highest and mid-values (Fig. 42). These areas of under- and over-prediction showed strong spatial pattern over the region (Fig. 42).

The semivariogram showed weak autocorrelation present in the data but an excellent fit between the predicted and measured values (Fig. 43). The kriged model showed poor cross-validation statistics (Table 18). The Standardized Root-Mean-Square Prediction Error was much lower than 1 indicating that variability in the predictions was overestimated. The error map showed a ‘bullseye’ pattern with error increasing with distance from data points (Fig. 44). The kriged surface is presented in Fig. 45.

Surface Temperature Minimum

This variable displayed a right-skewed, leptokurtic distribution prior to interpolation (Table 19, Fig. 46). The data were higher than predicted by a standard normal distribution at the tails and were lower than predicted at mid-range values (Fig. 47). These data points were spatially cohesive with big areas of over- and under-prediction (Fig. 47), with the former being more prevalent.

The semivariogram showed weak autocorrelation present in the data but an excellent fit between the predicted and measured values (Fig. 48). The kriged model showed fair cross-validation statistics (Table 20). The error map showed a ‘bullseye’ pattern with error increasing with distance from data points (Fig. 49). The kriged surface is presented in Fig. 50.

Average Standard Error	0.190

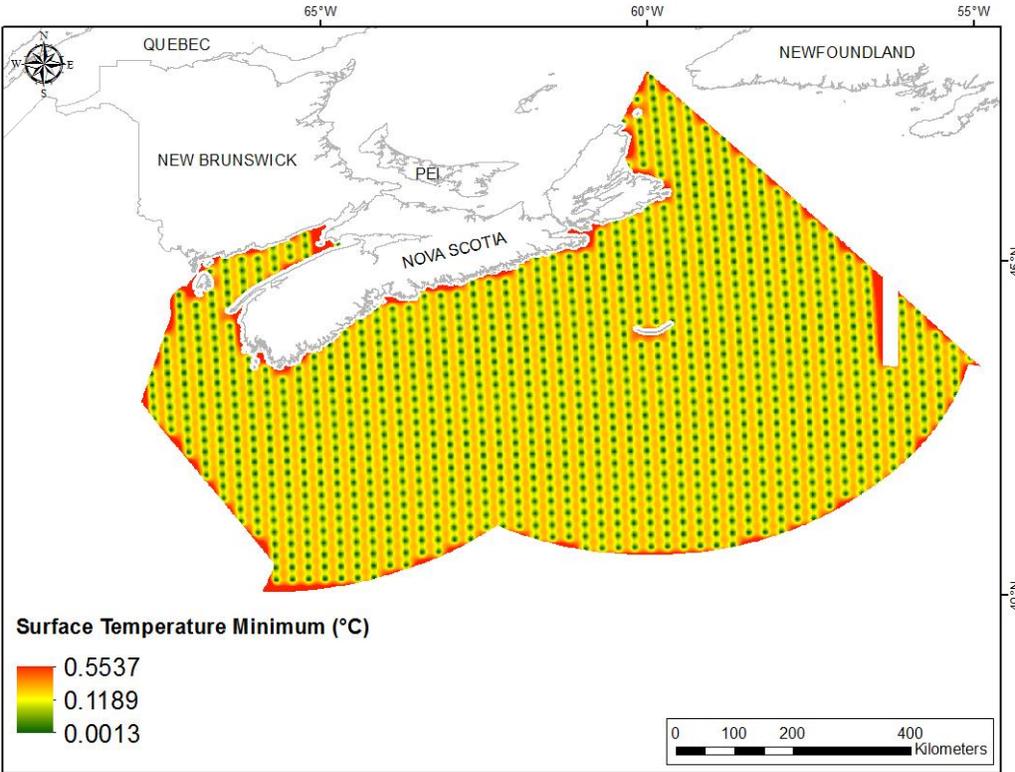

Fig. 49. Prediction standard error surface of Surface Temperature Minimum (°C).

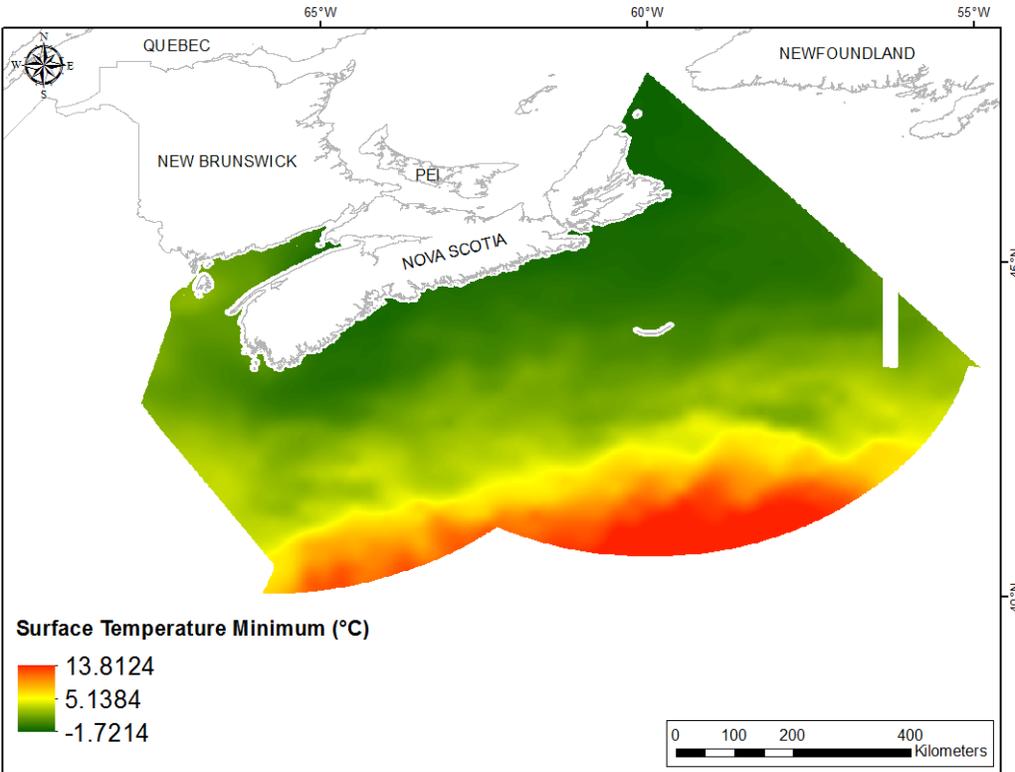

Fig. 50. Interpolated prediction surface of Surface Temperature Minimum (°C).

Surface Temperature Maximum

This variable displayed a platykurtic, bimodal distribution prior the modeling (Table 21, Fig. 51). The data were higher than predicted by a standard normal distribution at low and upper mid-values and lower than predicted at high and mid-values (Fig. 52). These data points were spatially cohesive across the region (Fig. 52).

The semivariogram showed fair autocorrelation present in the data but an excellent fit between measured and predicted values (Fig. 53). The kriged model showed fair cross-validation statistics (Table 22). The Standardized Root-Mean-Square Prediction Error was higher than 1 indicating that variability in the predictions has been underestimated. The error map showed high error along the edges of the study extent (Fig. 54). The kriged surface is presented in Fig. 55.

Overall Mean Error	-9.786×10^{-4}
Root Mean Square Prediction Error	0.141
Standardized Mean	-9.983×10^{-3}
Standardized Root Mean Square Prediction Error	1.828
Average Standard Error	0.088

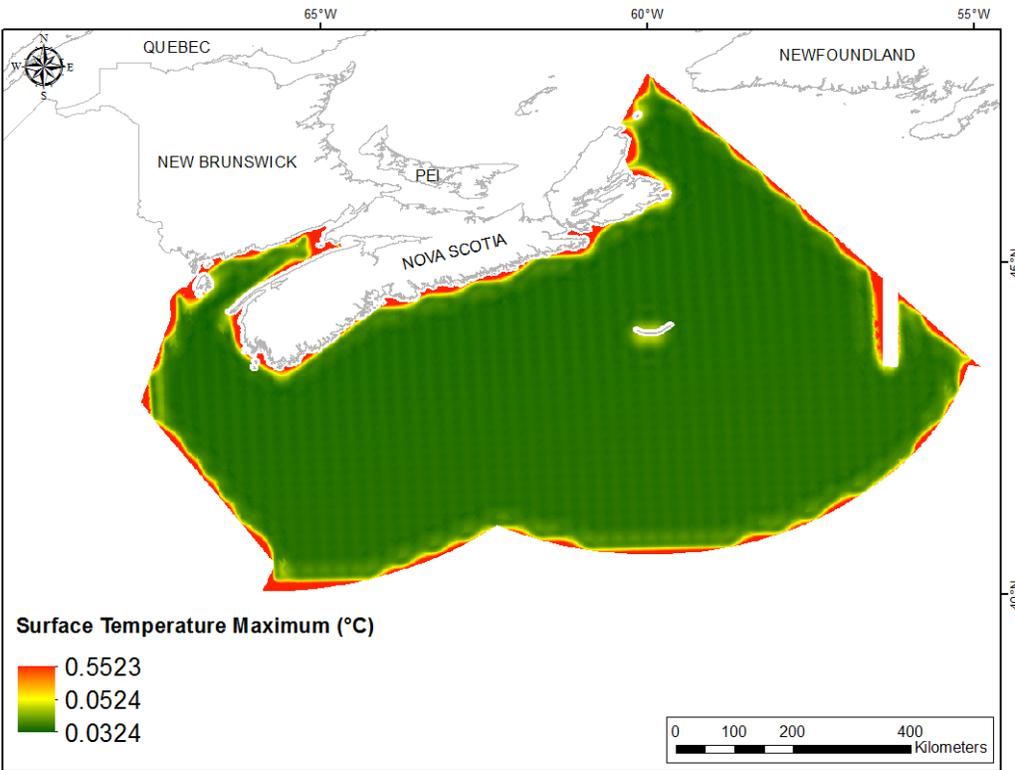

Fig. 54. Prediction standard error surface of Surface Temperature Maximum (°C).

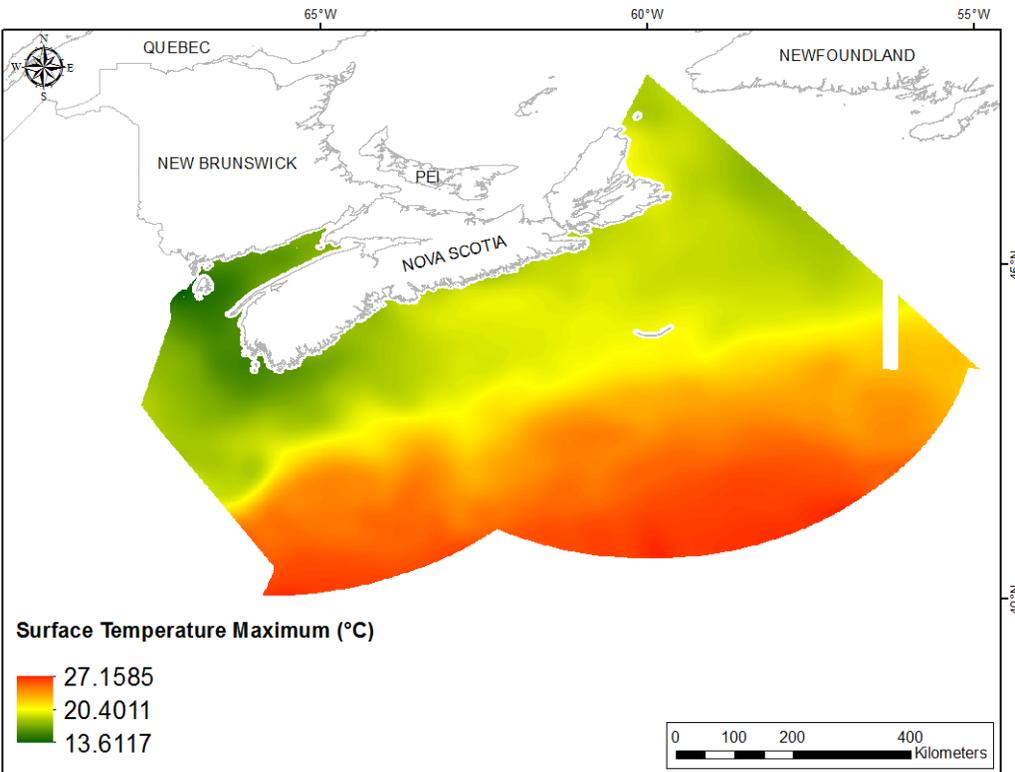

Fig. 55. Interpolated prediction surface of Surface Temperature Maximum (°C).

Surface Temperature Range

This variable displayed a left-skewed, leptokurtic distribution prior to interpolation (Table 23, Fig. 56). The data were greater than predicted by a standard normal distribution at mid-values and lower than predicted at both tails (Fig. 57). These areas of under- and over-prediction showed no strong spatial pattern over the region (Fig. 57).

The semivariogram showed moderate autocorrelation present in the data and good predictive fit (Fig. 58). The kriged model showed good cross-validation statistics indicating that it was good at prediction (Table 24). The error map showed a ‘bullseye’ pattern with error increasing with distance from data points (Fig. 59). The kriged surface is presented in Fig. 60.

Overall Mean Error	-1.376×10^{-3}
Root Mean Square Prediction Error	0.271
Standardized Mean	-1.967×10^{-3}
Standardized Root Mean Square Prediction Error	0.827
Average Standard Error	0.326

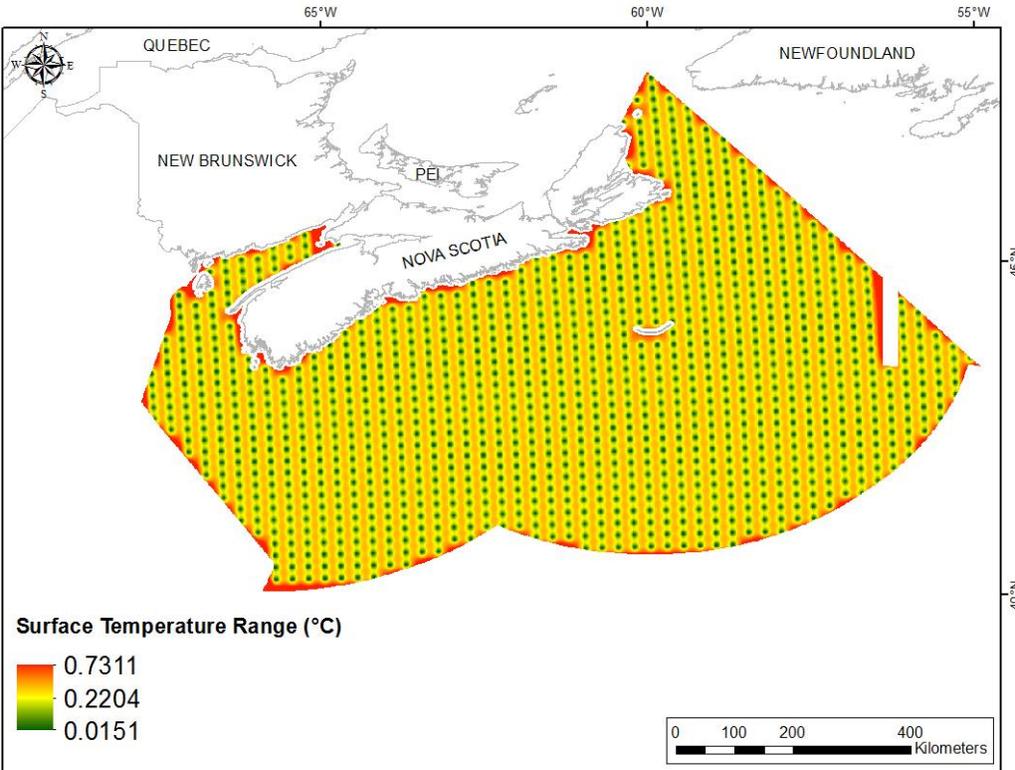

Fig. 59. Prediction standard error surface of Surface Temperature Range (°C).

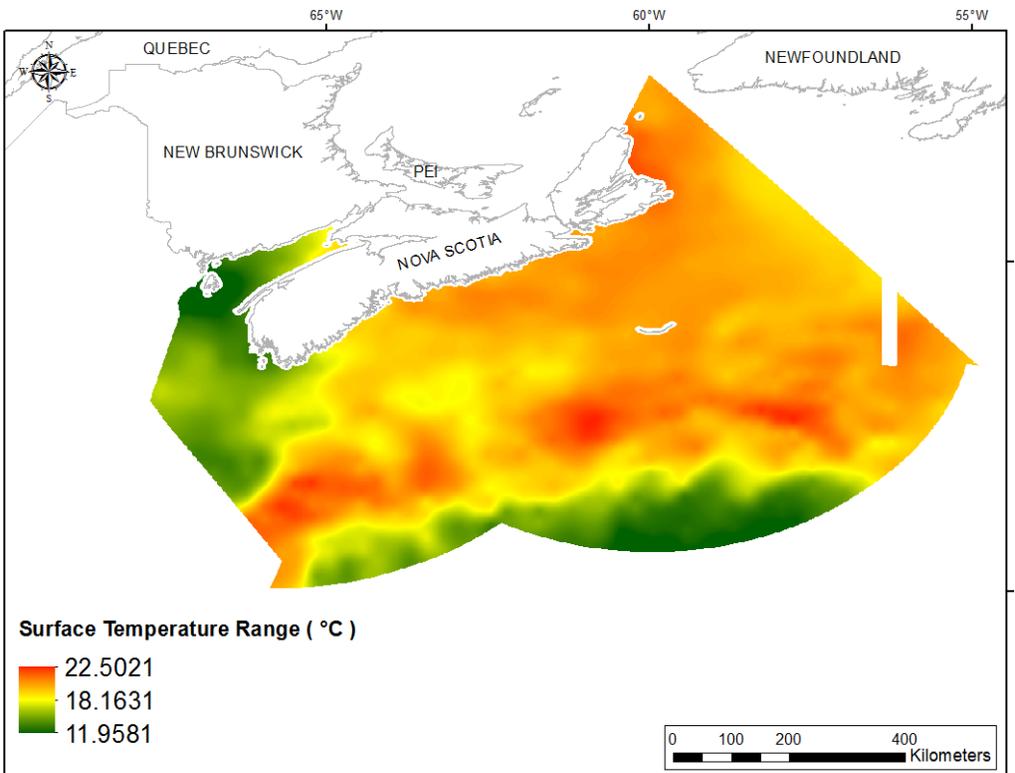

Fig. 60. Interpolated prediction surface of Surface Temperature Range (°C).

Surface Temperature Average Minimum

This variable displayed a right-skewed, platykurtic distribution prior to interpolation (Table 25, Fig. 61). The data were greater than predicted by a standard normal distribution at upper mid-range and low values, and lower than predicted at lower mid-range and highest values (Fig. 62). These data points were spatially cohesive with specific areas of over- and under-prediction (Fig. 62).

The semivariogram showed weak autocorrelation present in the data but an excellent predictive fit (Fig. 63). However, the model showed poor cross-validation statistics (Table 26). The Standardized Root-Mean-Square Prediction Error was lower than 1 indicating that variability in the predictions has been overestimated. The error map showed a ‘bullseye’ pattern with error increasing with distance from data points (Fig. 64). The kriged surface is presented in Fig. 65.

Surface Temperature Average Maximum

This variable displayed a platykurtic, right-skewed distribution prior to interpolation (Table 27, Fig. 66). The data showed deviations from a standard normal distribution with the lower tail and the upper mid-range values being higher than predicted and the upper tail and mid-values being lower than predicted by a normal distribution (Fig. 67). These data points were spatially cohesive with specific areas of over-and under-prediction (Fig. 67).

The semivariogram showed weak autocorrelation present in the data but excellent predictive fit (Fig. 68). The model showed good cross-validation statistics (Table 28) indicating that it was good at prediction. The error map showed high error along the edges of the study extent (Fig. 69). The kriged surface is presented in Fig. 70.

Surface Temperature Average Range

This variable displayed platykurtic, left-skewed distribution prior to interpolation (Table 29, Fig. 71). The data were greater than predicted by a standard normal distribution at mid-range and lowest values, and lower than predicted at lower mid-range and the highest values (Fig. 72). These areas of under- and over-prediction showed little spatial pattern over the region (Fig. 72).

The semivariogram showed weak autocorrelation present in the data and a poor fit between measured and predicted values (Fig. 73). However, the model showed good cross-validation statistics (Table 30). The error map showed high error along the edges of the study extent (Fig. 74). The kriged surface is presented in Fig. 75.

Salinity

Salinity influences osmoregulation (control of osmosis and diffusion) and is a very important determinant of species distribution. Salinity also strongly influences the rate at which inorganic particles settle in response to changes in flocculation of the clay mineral kaolinite (Sutherland et. al., 2014). This is particularly important in estuaries and deltas where clay minerals mix with marine waters. Salinity and temperature together are diagnostics of water masses which maintain characteristic T/S signatures.

Bottom Salinity Mean

This variable displayed a left-skewed, leptokurtic distribution with outlying data in the lower range prior to interpolation (Table 31, Fig. 76). The data deviated from a standard normal distribution with lower and upper values falling under the reference line (Fig. 77), and mid-values falling over the reference line. These data points were spatially cohesive across the region (Fig. 77).

The semivariogram showed very weak autocorrelation present in the data. Aside from a few outliers there was a good fit between measured and predicted values (Fig. 78). The kriged model showed good cross-validation statistics (Table 32). The error map showed high error along the edges of the study extent (Fig. 79). The kriged surface is presented in Fig. 80.

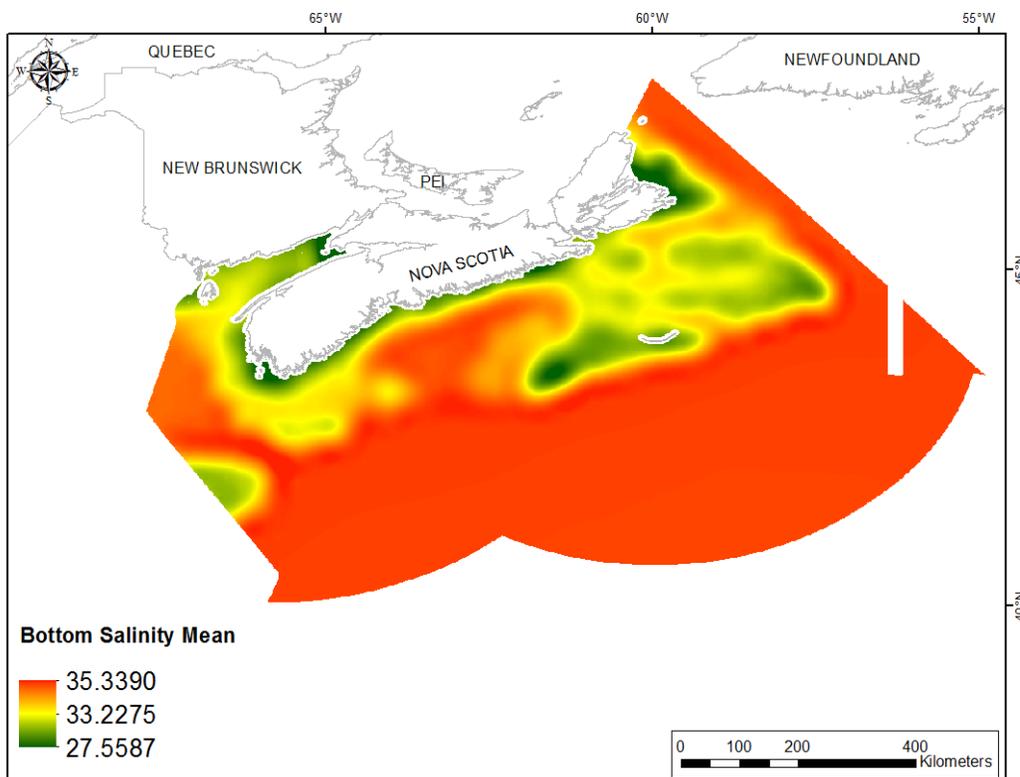

Fig. 80. Interpolated prediction surface of Bottom Salinity Mean.

Bottom Salinity Minimum

This variable displayed a left-skewed, leptokurtic distribution with outlying data in the lower range prior to interpolation (Table 33, Fig. 81). The data were lower than predicted by a normal distribution at low and high values (Fig. 82). Mid-range values were higher than the reference line. These data points showed some spatial cohesion across the region (Fig. 82).

The semivariogram showed very weak autocorrelation present in the data (Figure 83). Aside from a few outliers there was a good fit between measured and predicted values (Fig. 83). The kriged model showed good cross-validation statistics (Table 34). The error map showed high error along the edges of the study extent (Fig. 84). The kriged surface is presented in Fig. 85.

Bottom Salinity Maximum

This variable displayed a left-skewed, leptokurtic distribution with outlying data in the lower range prior to interpolation (Table 35, Fig. 86). The data were lower than predicted by a normal distribution at both tails (Fig. 87). Mid-range values were higher than the reference line. The areas of over- and under-prediction showed a spatial pattern through the study extent with points over the reference line located primarily in the deep water beyond the shelf (Fig. 87).

The semivariogram showed weak autocorrelation present in the data (Fig. 88). Aside from a single outlier there was a good fit between measured and predicted values (Fig. 88). The kriged model showed excellent cross-validation statistics (Table 36). The error map showed high error along the edges of the study extent (Fig. 89). The kriged surface is presented in Fig. 90.

Bottom Salinity Range

This variable displayed a right-skewed, leptokurtic distribution with outlying data in the upper range (Table 37, Fig. 91). The data were higher than predicted by a normal distribution at low and upper mid-range values and lower than predicted at mid-range and high values (Fig. 92). Values under and over the reference line showed a spatial pattern in the region (Fig. 92).

The semivariogram showed moderate autocorrelation present in the data (Fig. 93). Aside from a single outlier there was a fair fit between measured and predicted values (Fig. 93). The kriged model showed good cross-validation statistics (Table 38). The error map showed high error along the edges of the study extent (Fig. 94). The kriged surface is presented in Fig. 95. Negative values resulted from the right-skewed nature of the raw data (Fig. 91). Of the 326,283 raster cells in the study extent, 4,032 contained negative values (see Table A1). These were located in a long band along the lower slope (Fig. A3).

Bottom Salinity Average Range

This variable displayed a right-skewed, leptokurtic distribution with outlying data in the upper range prior to interpolation (Table 43, Fig. 106). The data were higher than predicted by a normal distribution at low and high values, and mid-range values were lower than the reference line (Fig. 107). There was a pattern to the under- and over-prediction (Fig. 107).

The semivariogram showed weak autocorrelation present in the data, however there was a good predictive fit (Fig. 108). The kriged model showed good cross-validation statistics (Table 44) indicating that it was good at prediction. The error map showed high error along the edges of the study extent (Fig. 109). The kriged surface is presented in Fig. 110. Negative values resulted from the right-skewed nature of the raw data (Fig. 106). Of the 326,283 raster cells in the study extent, 11,390 contained negative values (see Table A1). These were located in a long band along the lower slope (Fig. A4).

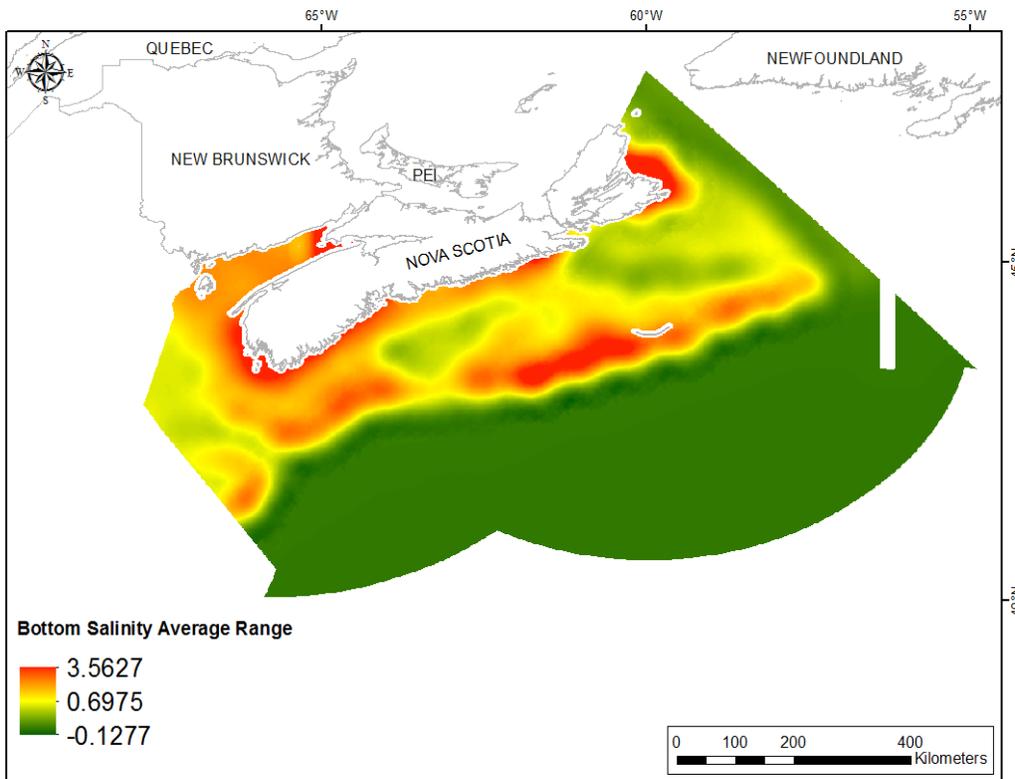

Fig. 110. Interpolated prediction surface of Bottom Salinity Average Range.

Surface Salinity Mean

This variable displayed a right-skewed, platykurtic distribution prior to interpolation (Table 45, Fig. 111). The data were lower than predicted by a normal distribution at mid-range and high values and higher than predicted at low and upper mid-range values (Fig. 112). There was a strong spatial pattern to the under- and over-predicted data points (Fig. 112).

The semivariogram showed moderate autocorrelation present in the data (Fig. 113). There was very good fit between the measured and predicted values (Fig. 113). However, the kriged model showed poor cross-validation statistics (Table 46). The Standardized Root-Mean-Square Prediction Error was less than 1 indicating that variability in the predictions has been overestimated. The error map showed high error along the edges of the study extent (Fig. 114). The kriged surface is presented in Fig. 115.

Prediction error	Value
Number of Observations	1160
Overall Mean Error	1.228×10^{-3}
Root Mean Square Prediction Error	0.037
Standardized Mean	9.698×10^{-3}
Standardized Root Mean Square Prediction Error	0.492
Average Standard Error	0.057

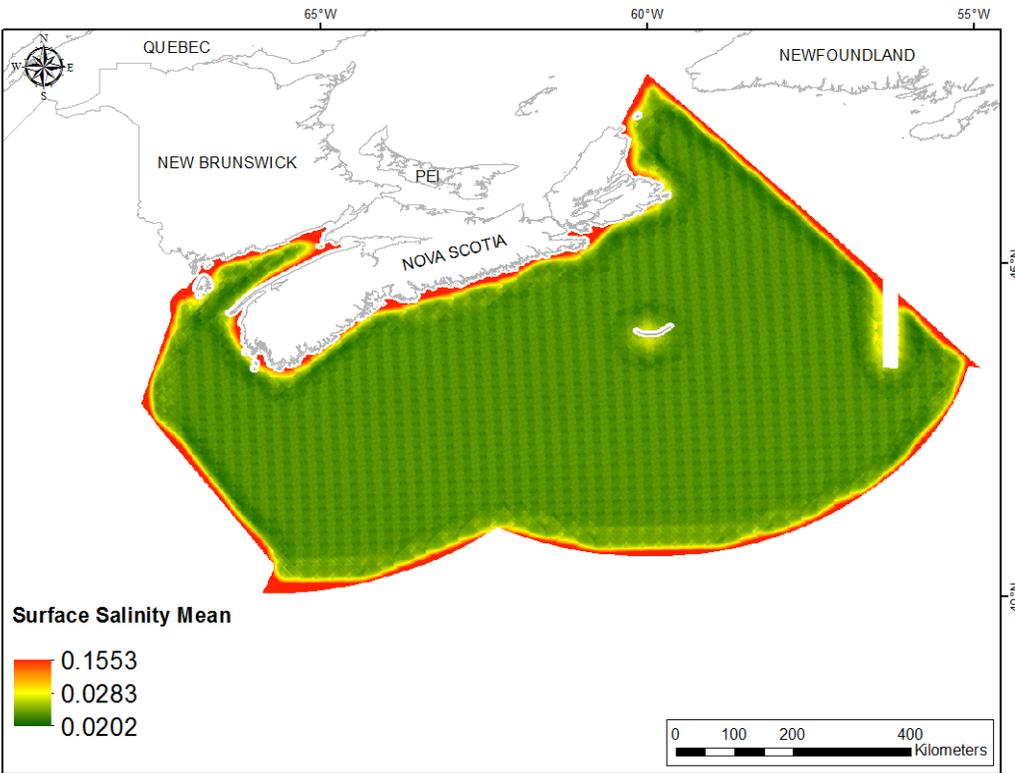

Fig. 114. Prediction standard error surface of Surface Salinity Mean.

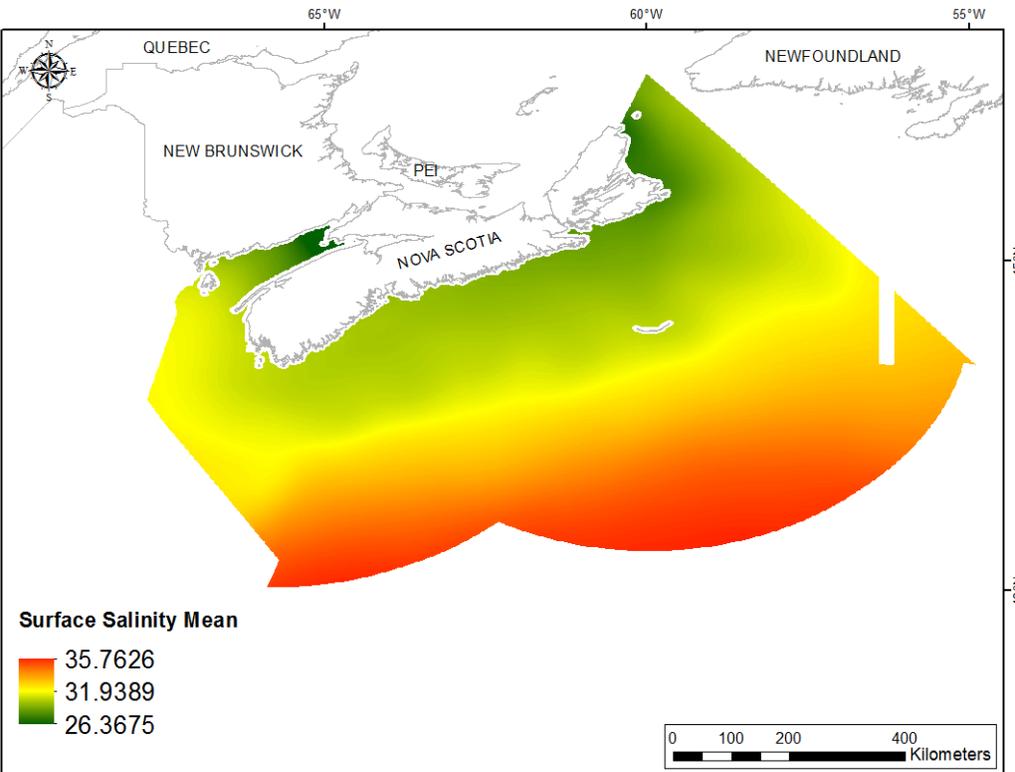

Fig. 115. Interpolated prediction surface of Surface Salinity Mean.

Surface Salinity Minimum

This variable displayed a left-skewed, leptokurtic distribution prior to interpolation (Table 47, Fig. 116). The data were lower than predicted by a normal distribution at both tails, while some mid-range values were above the reference line (Fig. 117). There was spatial pattern to the under- and over-prediction (Fig. 117).

The semivariogram showed weak autocorrelation present in the data (Fig. 118). The kriged model showed excellent fit between predicted and measured values (Fig. 118) but poor cross-validation statistics (Table 48). The Standardized Root-Mean-Square Prediction Error was greater than 1 indicating that variability in the predictions has been underestimated. The error map showed a ‘bullseye’ pattern with error increasing with distance from data points (Fig. 119). The kriged surface is presented in Fig. 120.

Standardized Mean	0.010
Standardized Root Mean Square Prediction Error	1.567
Average Standard Error	0.067

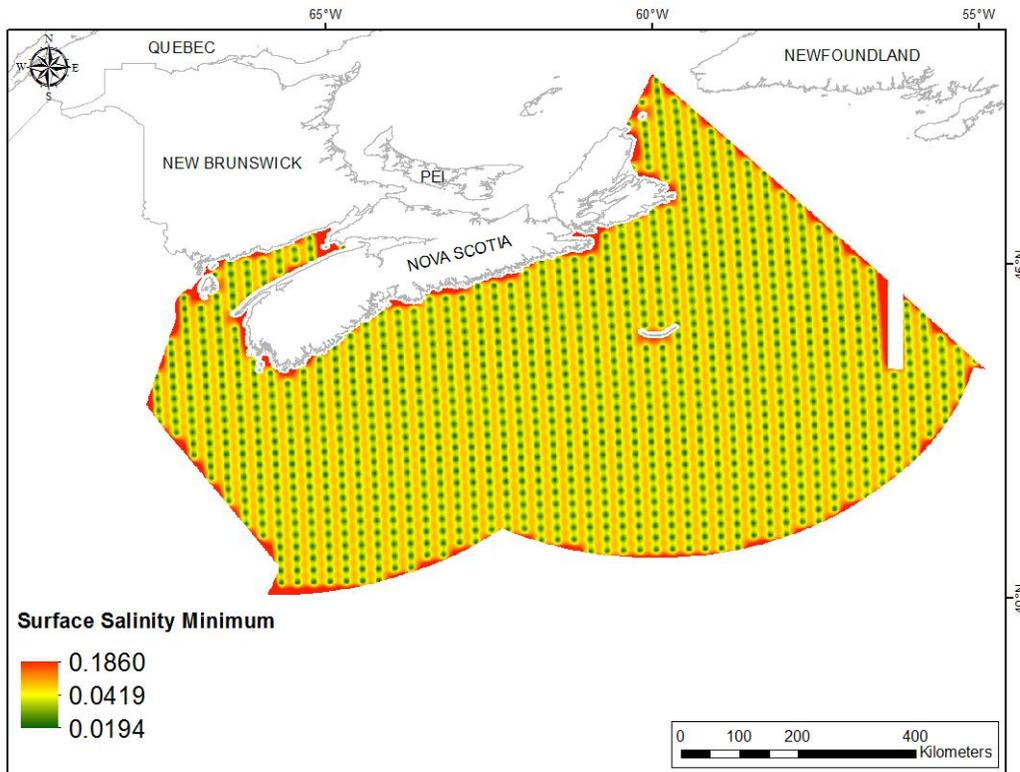

Fig. 119. Prediction standard error surface of Surface Salinity Minimum.

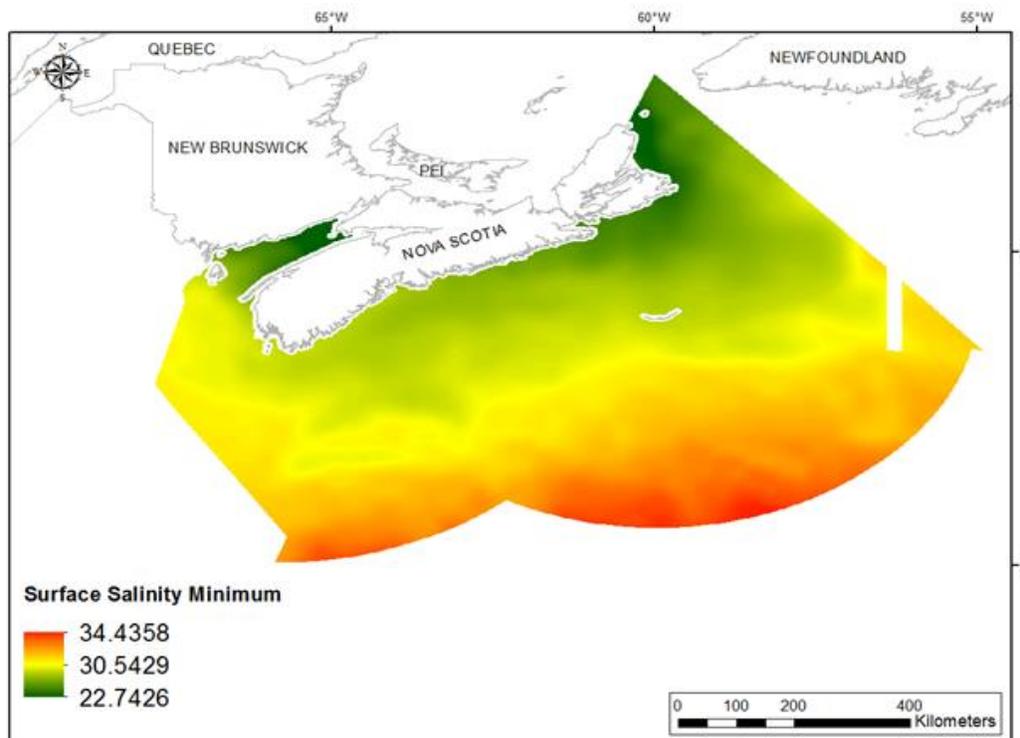

Fig. 120. Interpolated prediction surface of Surface Salinity Minimum.

Surface Salinity Maximum

This variable displayed a left-skewed, platykurtic and bimodal distribution prior to interpolation (Table 49, Fig. 121). The data were lower than predicted by a normal distribution at mid-range and high values (Fig. 122). Low- and upper mid-range values were higher than the reference line. There was spatial pattern to the under- and over-prediction (Fig. 122).

The semivariogram showed moderate autocorrelation present in the data and very good predictive fit (Fig. 123). The model showed fair cross-validation statistics (Table 50). The Standardized Root-Mean-Square Prediction Error was greater than 1 indicating that variability in the predictions has been underestimated. The error map showed a ‘bullseye’ pattern with error increasing with distance from data points (Fig. 124). The kriged surface is presented in Fig. 125.

Average Standard Error	0.053

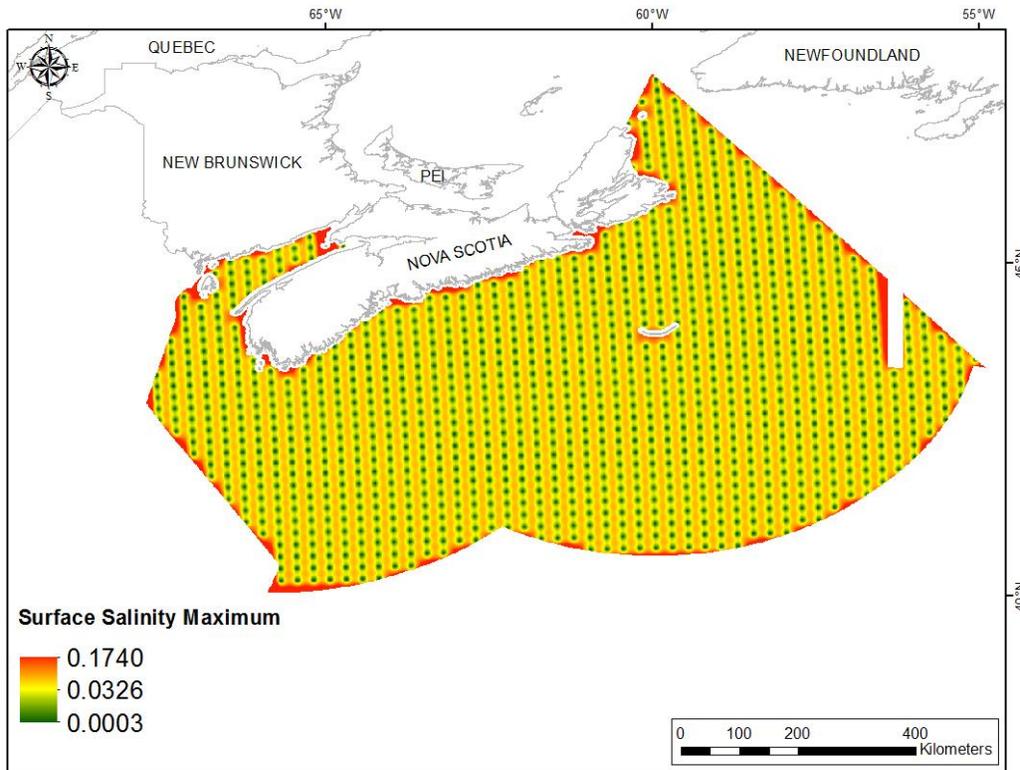

Fig. 124. Prediction standard error surface of Surface Salinity Maximum.

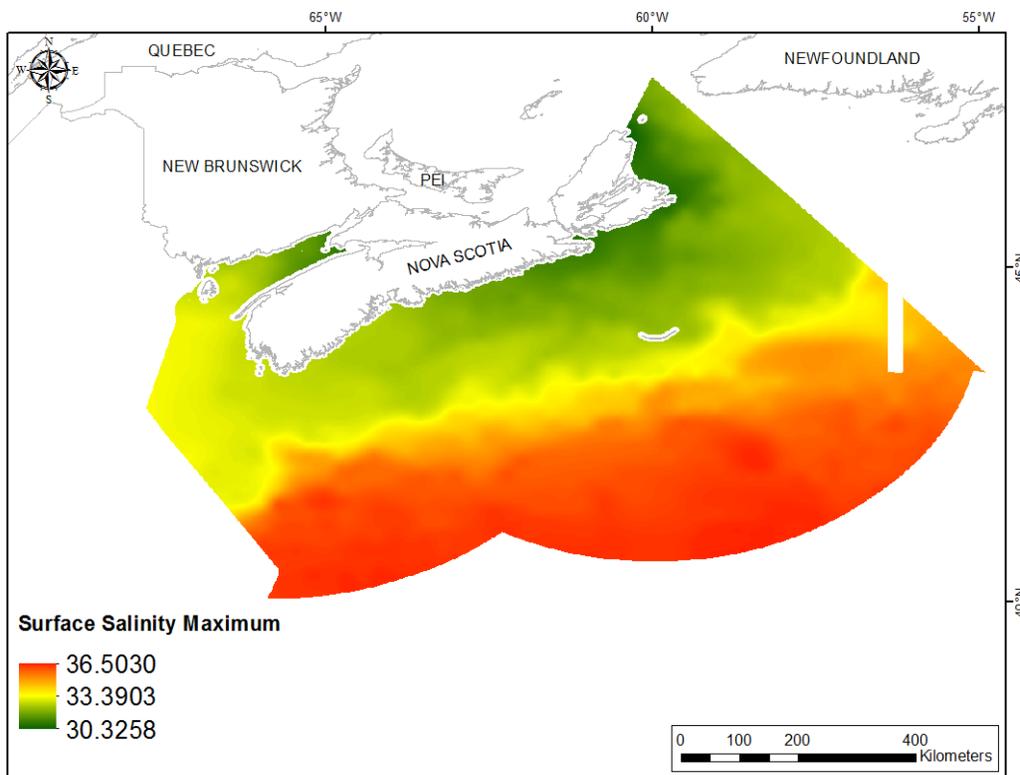

Fig. 125. Interpolated prediction surface of Surface Salinity Maximum.

Surface Salinity Range

This variable displayed a near-mesokurtic distribution with slight positive skew and outlying data in the upper range (Table 51, Fig. 126). The data were higher than predicted by a normal distribution at both tails, with mid-range values falling slightly below the reference line (Fig. 127). The areas of under- and over-prediction showed no strong spatial pattern over the study extent (Fig. 127).

The semivariogram showed autocorrelation present in the data (Fig. 128). The model showed a good fit between measured and predicted values (Fig. 128) and good cross-validation statistics indicating that it was good at prediction (Table 52). The error map showed a ‘bullseye’ pattern with error increasing with distance from data points (Fig. 129). The kriged surface is presented in Fig. 130.

Surface Salinity Average Minimum

This variable displayed a near-mesokurtic distribution with slight positive skew (Table 53, Fig. 131). The data were lower than predicted by a normal distribution at both tails with some mid-range values above the reference line (Fig. 132). There was a strong spatial pattern to the under- and over-prediction (Fig. 132).

The semivariogram showed weak autocorrelation present in the data (Fig. 133). There was an excellent fit between the measured and predicted values (Fig. 133), but the model showed poor cross-validation statistics (Table 54). The Standardized Root-Mean-Square Prediction Error was greater than 1 indicating that variability in the predictions has been underestimated. The error map showed a ‘bullseye’ pattern with error increasing with distance from data points (Fig. 134). The kriged surface is presented in Fig. 135.

Surface Salinity Average Maximum

This variable displayed a platykurtic, right-skewed distribution with bimodality prior to interpolation (Table 55, Fig. 136). The data were higher than predicted by a normal distribution at low and upper mid-range values and lower than predicted at mid-range and high values (Fig. 137). There was spatial pattern to the under- and over-prediction (Fig. 137).

The semivariogram showed weak to moderate autocorrelation present in the data (Fig. 138). There was an excellent fit between measured and predicted values (Fig. 138) and the model showed excellent cross-validation statistics (Table 56). The error map showed a ‘bullseye’ pattern with error increasing with distance from data points (Fig. 139). The kriged surface is presented in Fig. 140.

Average Standard Error	0.030

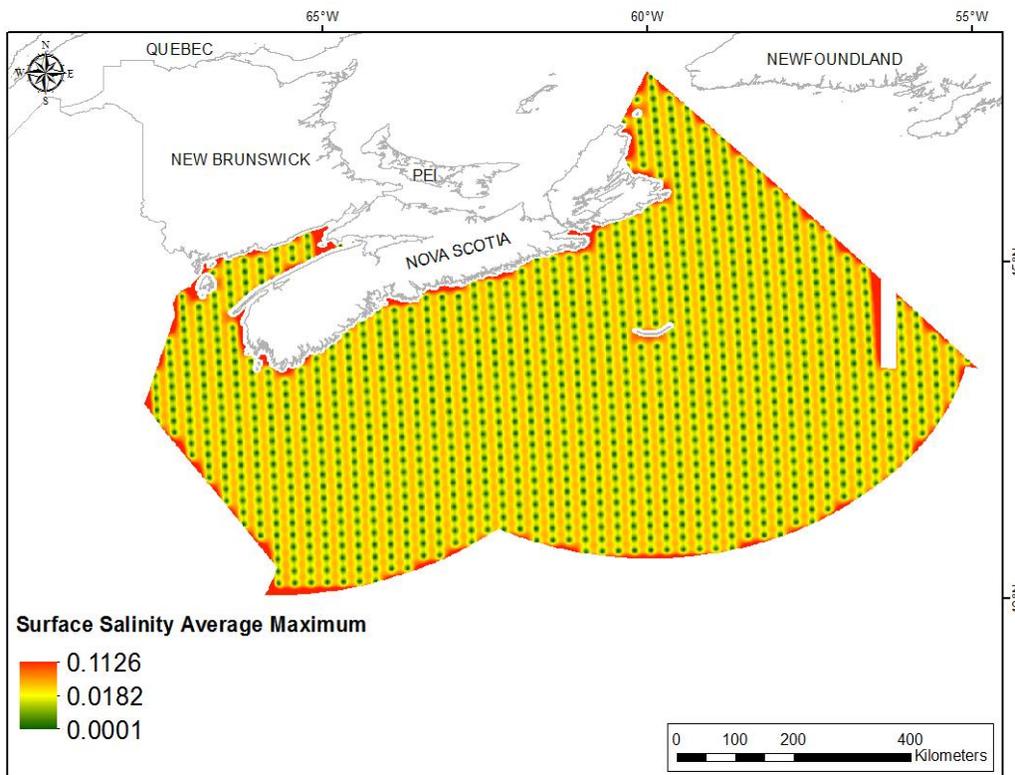

Fig. 139. Prediction standard error surface of Surface Salinity Average Maximum.

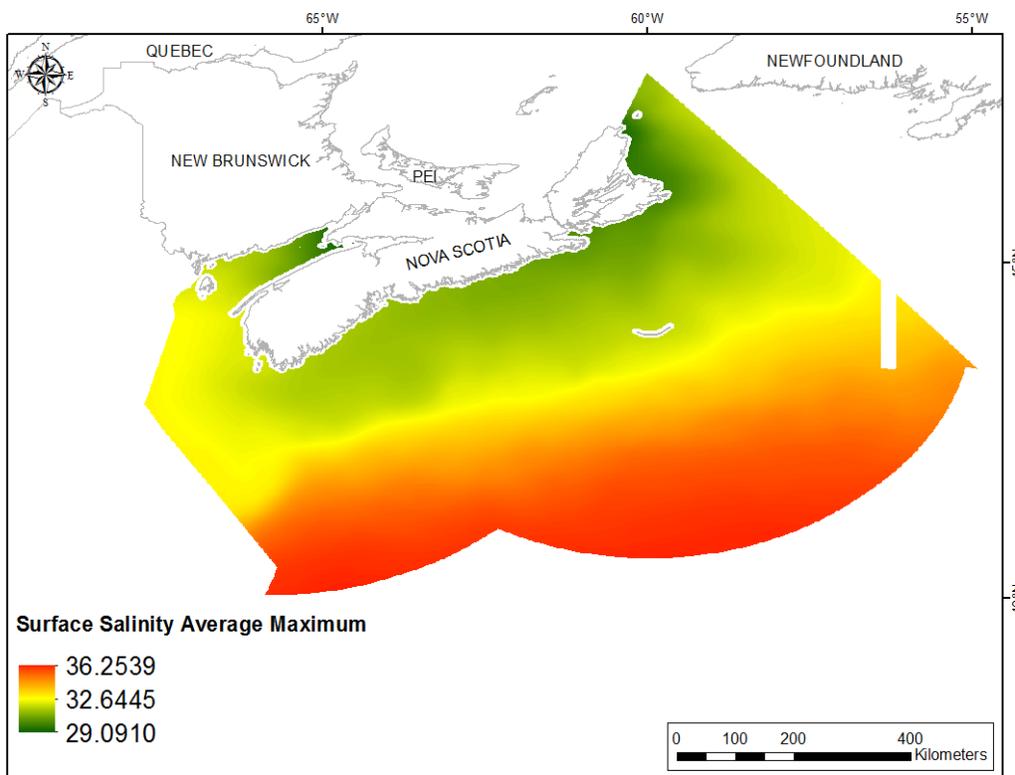

Fig. 140. Interpolated prediction surface of Surface Salinity Average Maximum.

Surface Salinity Average Range

This variable displayed a right-skewed, leptokurtic distribution prior to interpolation (Table 57, Fig. 141). The data were higher than predicted by a normal distribution at low and high values and slightly lower than predicted at mid-range values (Fig. 142). The areas of under- and over-prediction showed some spatial cohesion over the study extent (Fig. 142).

The semivariogram showed autocorrelation present in the data (Fig. 143). There was an excellent fit between measured and predicted values, particularly in the lower range (Fig. 143). However, the model showed poor cross-validation statistics (Table 58) with a standardized root mean square error greater than 1, indicating that variability in the predictions has been underestimated. The error map showed high error along the edges of the study extent (Fig. 144). The kriged surface is presented in Fig. 145.

Current Speed

Currents move water and heat around in the world's oceans and influence the chemical composition of the water column. Upwelling and downwelling currents strongly influence the distribution and abundance of marine life. Similarly, current speed determines the rate at which food particles reach benthic species through both vertical and horizontal transmission and consequently influences the distribution of filter-feeding species. Upwelling currents enhance productivity in the water column, while downwelling currents bring food and oxygen to the sea floor. Organisms also use currents for active and passive transport for migration and dispersal. Current speed can influence morphology, especially of marine macrophytes.

Bottom Current Mean

This variable displayed a right-skewed, leptokurtic distribution prior to interpolation (Table 59, Fig. 146). The data were higher than predicted by a normal distribution at both tails (Fig. 147). Mid-range values were lower than the reference line. The areas of over- and under-prediction showed little spatial pattern with both error types distributed throughout the study extent (Fig. 147).

The semivariogram showed moderate autocorrelation present in the data (Fig. 148). There was a fair fit between measured and predicted values (Fig. 148), and the model showed good cross-validation statistics (Table 60) indicating that it was good at prediction. The error map showed high error along the edges of the study extent (Fig. 149). The kriged surface is presented in Fig. 150.

Bottom Current Average Maximum

This variable displayed a right-skewed, leptokurtic distribution prior to interpolation (Table 69, Fig. 171). The data were higher than predicted by a normal distribution at both tails and lower at mid-range values (Fig. 172). The areas of over- and under-prediction did not show a strong spatial pattern with both error types distributed across the study extent (Fig. 172).

The semivariogram showed little autocorrelation present in the data and the model showed poor fit between measured and predicted values (Fig. 173). Nevertheless, the model showed good cross-validation statistics (Table 70) indicating that it was good at prediction. The error map showed high error along the edges of the study extent (Fig. 174). The kriged surface is presented in Fig. 175.

Bottom Current Average Range

This variable displayed a right-skewed, leptokurtic distribution prior to interpolation (Table 71, Fig. 176). The data were higher than predicted by a normal distribution at both tails, with mid-range values located below the reference line (Fig. 177). The areas of over- and under-prediction did not show a strong spatial pattern with both error types distributed across the study extent (Fig. 177).

The semivariogram showed weak autocorrelation present in the data and the model showed poor fit between measured and predicted values (Fig. 178). Nevertheless, the model showed good cross-validation statistics (Table 72) indicating that it was good at prediction. The error map showed high error along the edges of the study extent (Fig. 179). The kriged surface is presented in Fig. 180.

Surface Current Mean

This variable displayed a right-skewed, leptokurtic distribution prior to interpolation (Table 73, Fig. 181). The data were higher than predicted by a normal distribution at both tails, with mid-range values located below the reference line (Fig. 182). The areas of over- and under-prediction showed spatial cohesion across the study extent (Fig. 182).

The semivariogram showed weak autocorrelation present in the data (Fig. 183). There was an excellent fit between measured and predicted values (Fig. 183). The cross-validation statistics were fair (Table 74). The error map showed a ‘bullseye’ pattern with error increasing with distance from data points (Fig. 184). The kriged surface is presented in Fig. 185.

Surface Current Minimum

This variable displayed a right-skewed, leptokurtic distribution prior to interpolation (Table 75, Fig. 186). The data were higher than predicted by a normal distribution at both tails, with mid-range values located below the reference line (Fig. 187). The areas of over- and under-prediction showed little spatial pattern with both error types distributed randomly across the study extent (Fig. 187).

The semivariogram showed weak autocorrelation present in the data, with a poor fit between measured and predicted values (Fig. 188). Nevertheless, good performance of the model was indicated by the good cross-validation statistics (Table 76). The error map showed a ‘bullseye’ pattern with error increasing with distance from data points (Fig. 189). The kriged surface is presented in Fig. 190.

Surface Current Range

This variable displayed a right-skewed, platykurtic distribution prior to interpolation (Table 79, Fig. 196). The data were higher than predicted by a normal distribution at both tails, with mid-range values located below the reference line (Fig. 197). The areas of over- and under-prediction showed spatial pattern (Fig. 197).

The semivariogram showed weak autocorrelation present in the data and the model (Fig. 198). However, there was a good fit between measured and predicted values (Fig. 198), and the model showed good cross-validation statistics (Table 80). The error map showed a ‘bullseye’ pattern with error increasing with distance from data points (Fig. 199). The kriged surface is presented in Fig. 200.

Surface Current Average Minimum

This variable displayed slight positive skew and leptokurtosis prior to interpolation (Table 81, Fig. 201). The data were higher than predicted by a normal distribution at both tails, with mid-range values located below the reference line (Fig. 202). The areas of over- and under-prediction showed a slight spatial pattern (Fig. 202).

The semivariogram showed moderate autocorrelation present in the data and the model showed fair fit between measured and predicted values (Fig. 203). Nevertheless, the model showed good cross-validation statistics (Table 82) indicating that it was good at prediction. The error map showed low error and no strong spatial pattern over the study extent although error was highest along the coast and in deep waters (Fig. 204). The kriged surface is presented in Fig. 205.

Table 81. Distributional properties of Surface Current Average Minimum (m s^{-1}).

Property	Value
Number of Observations	1152

Standardized Mean	4.886×10^{-3}
Standardized Root Mean Square Prediction Error	1.102
Average Standard Error	3.531×10^{-3}

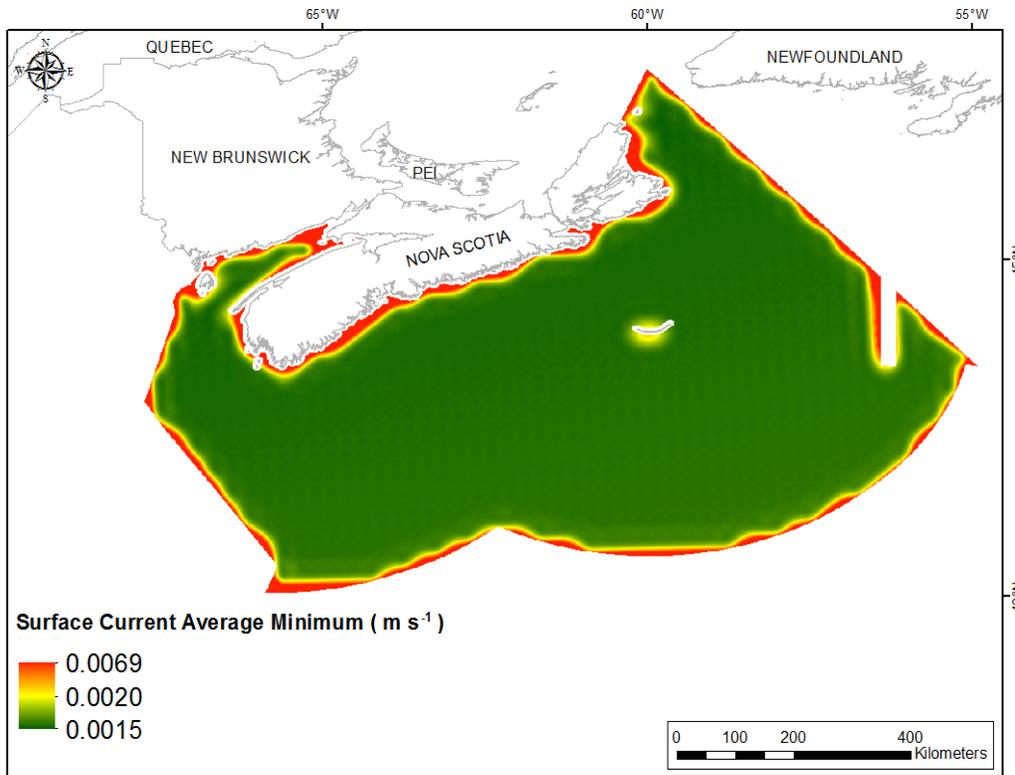

Fig. 204. Prediction standard error surface of Surface Current Average Minimum (m s^{-1}).

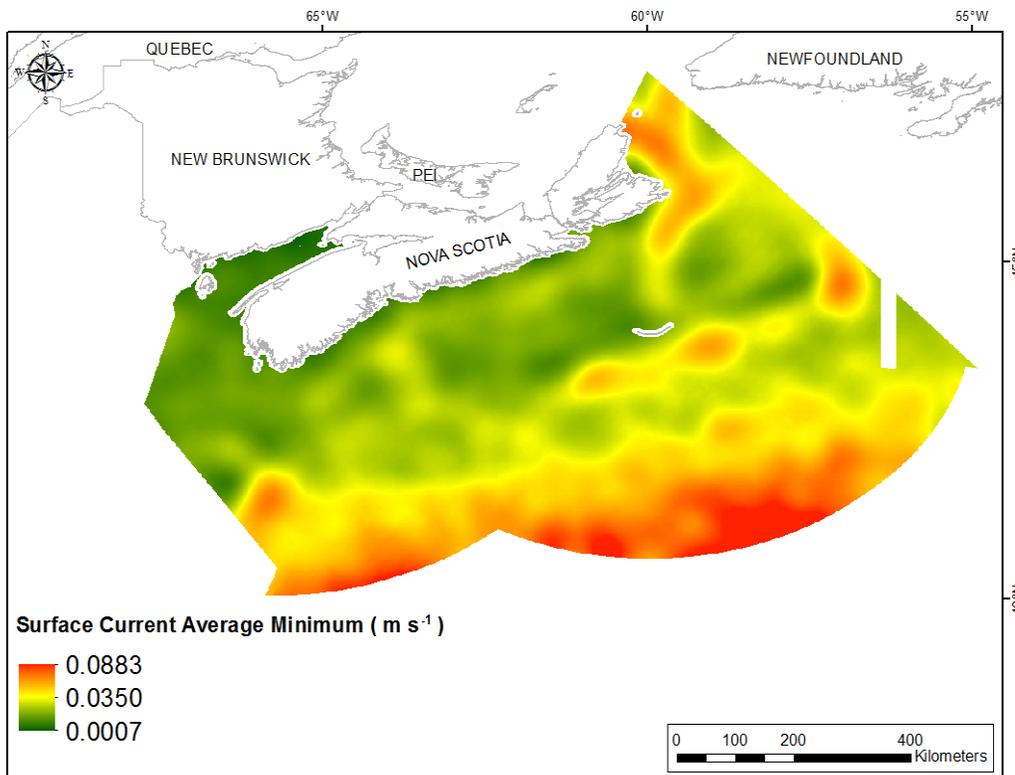

Fig. 205. Interpolated prediction surface of Surface Current Average Minimum (m s^{-1}).

Surface Current Average Maximum

This variable displayed a slightly right-skewed distribution prior to interpolation (Table 83, Fig. 206). The data were higher than predicted by a normal distribution at both tails, with mid-range values located below the reference line (Fig. 207). The areas of over- and under-prediction showed a strong spatial pattern (Fig. 207).

The semivariogram showed weak autocorrelation present in the data (Fig. 208). The model showed excellent fit between measured and predicted values (Fig. 208), but poor performance was indicated by the cross-validation statistics (Table 84). The Standardized Root-Mean-Square Prediction Error was less than 1, indicating that variability in the predictions has been overestimated. The error map showed a ‘bullseye’ pattern with error increasing with distance from data points (Fig. 209). The kriged surface is presented in Fig. 210.

Surface Current Average Range

This variable displayed a slightly right-skewed distribution prior to interpolation (Table 85, Fig. 211). The data were higher than predicted by a normal distribution at both tails, with mid-range values located below the reference line (Fig. 212). The areas of over- and under-prediction showed a strong spatial pattern (Fig. 212).

The semivariogram showed weak autocorrelation present in the data (Fig. 213). The model showed excellent fit between measured and predicted values (Fig. 213), and good performance was indicated by the cross-validation statistics (Table 86). The error map showed a ‘bullseye’ pattern with error increasing with distance from data points (Fig. 214). The kriged surface is presented in Fig. 215.

Maximum Seasonal Mixed Layer Depth

Maximum mixed layer depth, or, the depth at which surface vertical mixing dissipates, is a near-universal feature of the open ocean (de Boyer Montégut et al., 2004). Within this mixed layer, salinity, temperature, or density are nearly uniform, a phenomenon caused by surface forcing, lateral advection, and internal wave processes that vary on diurnal, intra-seasonal, seasonal, and inter-annual scales (de Boyer Montégut et al., 2004). The depth of this mixed zone can show large spatial variability, ranging from less than 20 m in the summer hemisphere, to more than 500 m in the winter hemisphere at subpolar latitudes (de Boyer Montégut et al., 2004). The mixed layer depth has a significant influence on primary production in the surface waters. As the mixed layer depth increases it entrains nutrients from deeper waters below, supplying additional nutrients for primary production (Polovina et al., 1995; Carstensen et al., 2002).

Maximum Spring Mixed Layer Depth

This variable displayed a right-skewed distribution prior to interpolation (Table 87, Fig. 216). The data were higher than predicted by a normal distribution at both tails, with mid-range values located below the reference line (Fig. 217). The areas of over- and under-prediction showed no strong spatial pattern (Fig. 217).

The semivariogram showed weak autocorrelation present in the data (Fig. 218). The model showed a good fit between measured and predicted values (Fig. 218), but only fair performance as indicated by the cross validation statistics (Table 88). The error map showed a ‘bullseye’ pattern with error increasing with distance from data points (Fig. 219). The kriged surface is presented in Fig. 220.

Maximum Summer Mixed Layer Depth

This variable displayed a right-skewed distribution and slight bimodality prior to interpolation (Table 89, Fig. 221). The data were higher than predicted by a normal distribution at both tails, with mid-range values located below the reference line (Fig. 222). The areas of over- and under-prediction showed a spatial pattern (Fig. 222).

The semivariogram showed weak autocorrelation present in the data (Fig. 223). The model showed a good fit between measured and predicted values (Fig. 223), but only fair performance as indicated by the cross validation statistics (Table 90). The error map showed a ‘bullseye’ pattern with error increasing with distance from data points (Fig. 224). The kriged surface is presented in Fig. 225.

Maximum Fall Mixed Layer Depth

This variable displayed a right-skewed, leptokurtic distribution prior to interpolation (Table 91, Fig. 226). The data were higher than predicted by a normal distribution at both tails, with mid-range values located below the reference line (Fig. 227). The areas of over- and under-prediction showed spatial pattern (Fig. 227).

The semivariogram showed weak autocorrelation present in the data (Fig. 228). The model showed a good fit between measured and predicted values (Fig. 228), and good performance as indicated by the cross validation statistics (Table 92). The error map showed a ‘bullseye’ pattern with error increasing with distance from data points (Fig. 229). The kriged surface is presented in Fig. 230.

Maximum Winter Mixed Layer Depth

This variable displayed a right-skewed distribution and kurtosis (Table 93, Fig. 231). The data were higher than predicted by a normal distribution at both tails, with mid-range values located below the reference line (Fig. 232). The areas of over- and under-prediction showed a strong spatial pattern (Fig. 232).

The semivariogram showed little to no autocorrelation present in the data (Fig. 233). The model showed a good fit between measured and predicted values (Fig. 233), and good performance was indicated by the cross-validation statistics (Table 94). The error map showed a ‘bullseye’ pattern with error increasing with distance from data points (Fig. 234). The kriged surface is presented in Fig. 235.

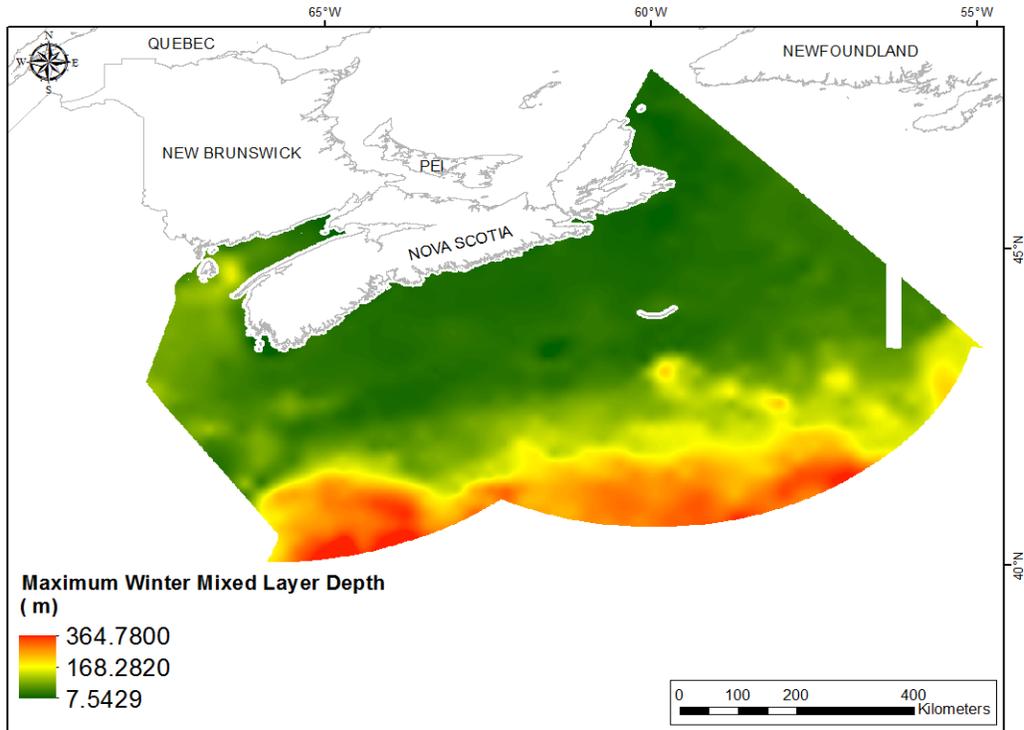

Fig. 235. Interpolated prediction surface of Maximum Winter Mixed Layer Depth (m).

Maximum Average Spring Mixed Layer Depth

This variable displayed a right-skewed, leptokurtic distribution prior to interpolation (Table 95, Fig. 236). The data were higher than predicted by a normal distribution at both tails, with mid-range values located below the reference line (Fig. 237). The areas of over- and under-prediction showed spatial pattern (Fig. 237).

The semivariogram showed weak autocorrelation present in the data (Fig. 238). The model showed a good fit between measured and predicted values (Fig. 238), but poor performance was indicated by the poor cross-validation statistics (Table 96). The Standardized Root-Mean-Square Prediction Error was greater than 1 indicating that variability in the predictions has been underestimated. The error map showed high error along the edges of the study extent (Fig. 239). The kriged surface is presented in Fig. 240.

Maximum Average Summer Mixed Layer Depth

This variable displayed a right-skewed, leptokurtic distribution prior to interpolation (Table 97, Fig. 241). The data were higher than predicted by a normal distribution at both tails, with mid-range values located below the reference line (Fig. 242). The areas of over- and under-prediction showed spatial pattern (Fig. 242).

The semivariogram showed weak autocorrelation present in the data (Fig. 243). The model showed an excellent fit between measured and predicted values (Fig. 243), with fair performance indicated by the cross-validation statistics (Table 98). The error map showed a ‘bullseye’ pattern with error increasing with distance from data points (Fig. 244). The kriged surface is presented in Fig. 245.

Maximum Average Fall Mixed Layer Depth

This variable displayed a right-skewed, slightly bimodal distribution prior to interpolation (Table 99, Fig. 246). The data were higher than predicted by a normal distribution at low and high values, with mid-range and the highest values located below the reference line (Fig. 247). The areas of over- and under-prediction showed spatial pattern (Fig. 247).

The semivariogram showed weak autocorrelation present in the data (Fig. 248). The model showed an excellent fit between measured and predicted values (Fig. 248), but poor performance was indicated by the cross-validation statistics (Table 100). The Standardized Root-Mean-Square Prediction Error was greater than 1 indicating that variability in the predictions has been underestimated. The error map showed a ‘bullseye’ pattern with error increasing with distance from data points (Fig. 249). The kriged surface is presented in Fig. 250.

Bottom Shear

Bottom shear stress is a function of the maximum predicted tidal current and reflects friction pressure on the seabed. Its unit is Pa or pascal, which is equivalent to one newton (1 N) of force over one meter squared. Shear stress near the seabed causes sediment erosion and affects vertical mixing and conditions conducive to sediment deposition (Cheng et al., 1999).

Bottom Shear Mean

This variable displayed a right-skewed distribution and extreme leptokurtosis prior to interpolation (Table 103, Fig. 256). The data were higher than predicted by a normal distribution at both tails, with mid-range values located below the reference line (Fig. 257). The areas of over- and under-prediction showed a weak spatial pattern (Fig. 257).

The semivariogram showed weak autocorrelation present in the data (Fig. 258). The model showed fair fit between measured and predicted values (Fig. 258), and good performance was indicated by the cross-validation statistics (Table 104). The error map showed high error along the edges of the study extent (Fig. 259). The kriged surface is presented in Fig. 260.

Bottom Shear Minimum

This variable displayed a right-skewed distribution with extreme leptokurtosis and outlying data in the upper range (Table 105, Fig. 261). The data were higher than predicted by a normal distribution at both tails, with mid-range values located below the reference line (Fig. 262). The areas of over- and under-prediction showed no spatial pattern (Fig. 262).

The semivariogram showed weak autocorrelation present in the data and the model showed very poor fit between measured and predicted values (Fig. 263). Nevertheless, good performance was indicated by the cross-validation statistics (Table 106). The error map showed high error along the edges of the study extent (Fig. 264). The kriged surface is presented in Fig. 265.

Bottom Shear Average Range

This variable displayed a right-skewed, highly leptokurtic distribution prior to interpolation (Table 115, Fig. 286). The data were higher than predicted by a normal distribution at both tails, with mid-range values located below the reference line (Fig. 287). The areas of over- and under-prediction showed no strong spatial pattern (Fig. 287).

The semivariogram showed weak autocorrelation present in the data and the model showed a fair fit between measured and predicted values (Fig. 288). Nevertheless, good performance of the model was indicated by the good cross-validation statistics (Table 116). The error map showed high error along the edges of the study extent (Fig. 289). The kriged surface is presented in Fig. 290.

Sea Surface Chlorophyll *a*

Sea surface chlorophyll *a* concentration is a proxy for phytoplankton biomass and is therefore related to the vertical flux of particulate organic carbon and food supply to the seafloor (Lutz et al., 2007). Gradients in food supply have often been identified as the main factor in controlling changes in benthic biomass, diversity, distribution, and zonation in the deep sea (Levin et al., 2001; Carney, 2005; Soltwedel et al., 2009; MacDonald et al., 2010; Papiol et al., 2012). In the northwest Atlantic, surface chlorophyll *a* has shown to be an important determinant in generalized linear models of megafaunal abundance and richness (Beazley et al. 2013) and was an important variable in random forest models predicting the presence of *Geodia* sponge and sponge grounds (Knudby et al., 2013). The spring phytoplankton bloom is thought to be a controlling factor in the reproductive cycles of several deep-sea corals (Sun et al., 2010a; 2010b; 2011; Mercier and Hamel, 2011) and sponges (Spetland et al., 2007) in the North Atlantic. Therefore, we expect that seasonal rather than annual measures of chlorophyll *a* will be more important in species distribution models.

Spring Chlorophyll *a* Mean

This variable displayed a right-skewed distribution with extreme leptokurtosis prior to interpolation (Table 117, Fig. 291). The data were higher than predicted by a normal distribution at both tails and lower than predicted at mid-values (Fig. 292). The areas of under- and over-prediction showed spatial pattern over the study extent (Fig. 292).

The semivariogram showed weak autocorrelation present in the data and the model showed a very good fit between measured and predicted values (Fig. 293). Nevertheless, poor performance of the model was indicated by the poor cross-validation statistics (Table 118). The Standardized Root-Mean-Square Prediction Error was greater than 1 indicating that variability in the predictions has been underestimated. The error map showed low error across the study extent (Fig. 294). The kriged surface is presented in Fig. 295.

Spring Chlorophyll *a* Range

This variable displayed a right-skewed, highly leptokurtic distribution prior to interpolation (Table 123, Fig. 306). The data were higher than predicted by a normal distribution at both tails and lower than predicted at mid-values (Fig. 307). The areas of under- and over-prediction showed no spatial pattern over the study extent (Fig. 307).

The semivariogram showed moderate autocorrelation present in the data and the model showed good fit between measured and predicted values (Fig. 308). Fair performance was indicated by the cross-validation statistics (Table 124). The error map showed medium error in a grid-like pattern over the study extent (Fig. 309). The kriged surface is presented in Fig. 310. Negative values resulted from the right-skewed nature of the raw data (Fig. 306). Of the 326,283 raster cells in the study extent, only 2 contained negative values (see Table A1). These were located together near the southern edge of the study extent above the abyssal plan (Fig. A5).

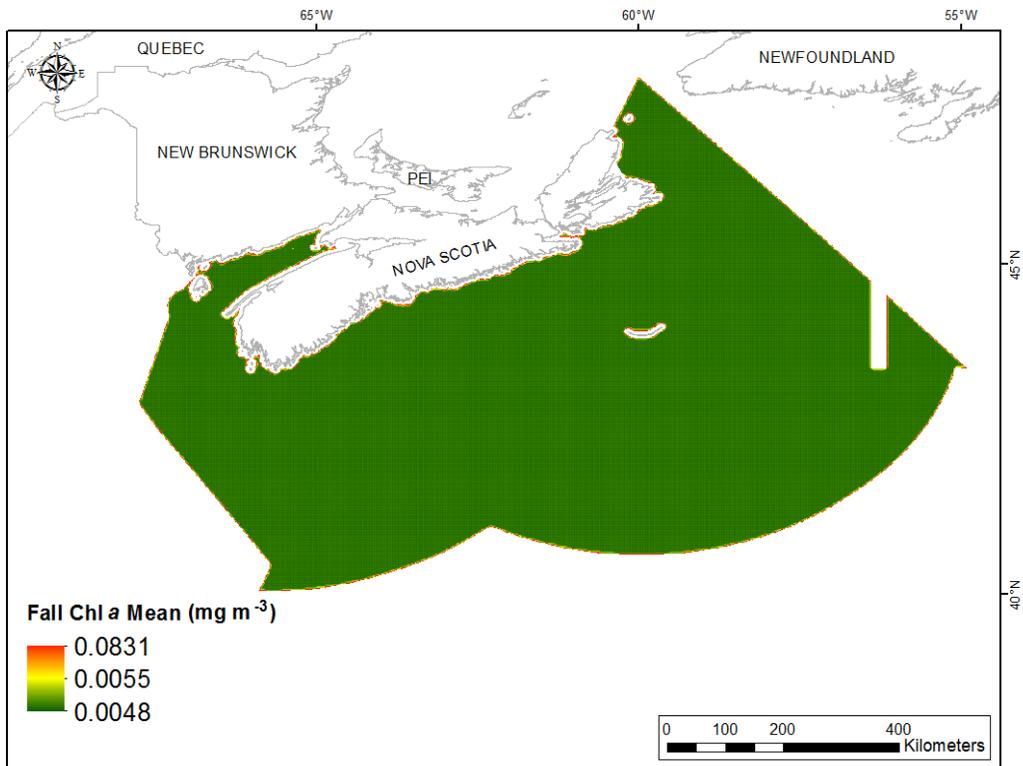

Fig. 334. Prediction standard error surface of Fall Chlorophyll *a* Mean (mg m^{-3}).

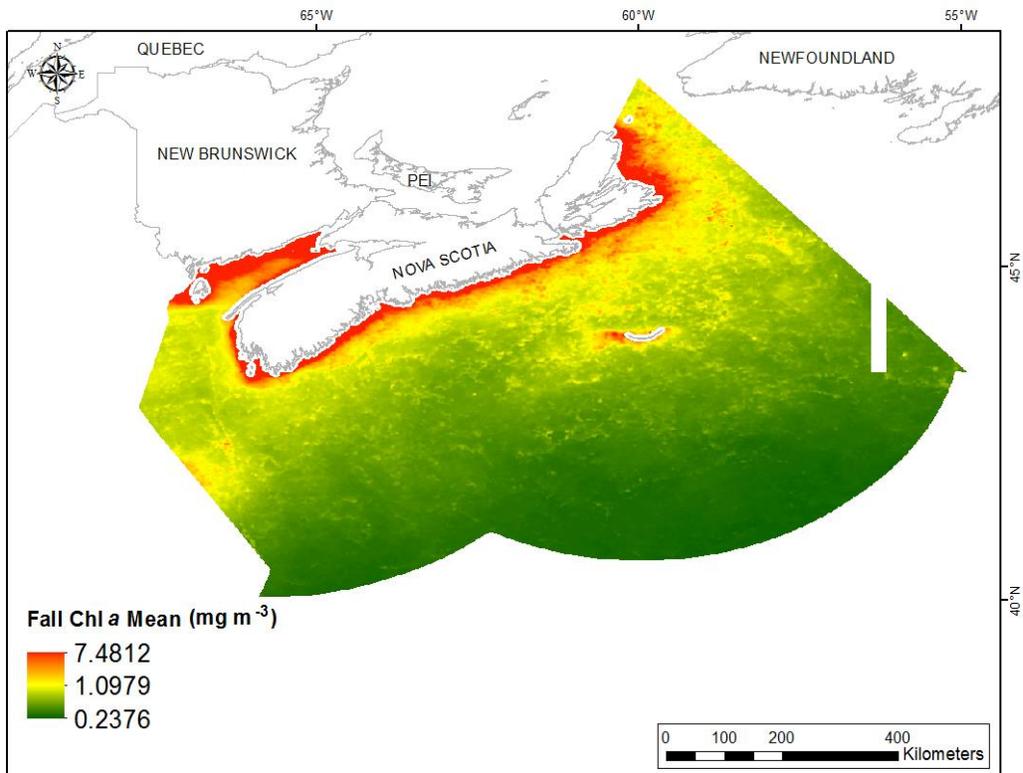

Fig. 335. Interpolated prediction surface of Fall Chlorophyll *a* Mean (mg m^{-3}).

Fall Chlorophyll *a* Minimum

This variable displayed a right-skewed, highly leptokurtic distribution prior to interpolation (Table 135, Fig. 336). The data were higher than predicted by a normal distribution at the upper range and slightly lower than predicted at mid-values (Fig. 337). The areas of under- and over-prediction showed a strong spatial pattern over the study extent (Fig. 337).

The semivariogram showed weak autocorrelation present in the data (Fig. 338). There was a very good fit between measured and predicted values (Fig. 338). Fair performance was indicated by the cross-validation results (Table 136), although the Standardized Root-Mean-Square Prediction Error was greater than 1 indicating that variability in the predictions has been underestimated. The error map showed low error over the study extent with high error in areas without data points (Fig. 339). The kriged surface is presented in Fig. 340.

Fall Chlorophyll *a* Maximum

This variable displayed a right-skewed, highly leptokurtic distribution prior to interpolation (Table 137, Fig. 341). The data were higher than predicted by a normal distribution at both tails and slightly lower than predicted at mid-values (Fig. 342). The areas of under- and over-prediction showed some spatial pattern over the study extent (Fig. 342).

The semivariogram showed moderate autocorrelation present in the data and the model showed fair fit between measured and predicted values (Fig. 343). Good performance of the model was indicated by the good cross-validation results (Table 138). The error map showed medium to high error in a grid-like pattern over the study extent (Fig. 344). The kriged surface is presented in Fig. 345.

Annual Chlorophyll *a* Mean

This variable displayed a right-skewed, highly leptokurtic distribution prior to interpolation (Table 141, Fig. 351). The data were higher than predicted by a normal distribution at both tails and lower than predicted at mid-values (Fig. 352). The areas of under- and over-prediction showed a very strong spatial pattern over the study extent (Fig. 352).

The semivariogram showed weak autocorrelation present in the data and the model showed a very good fit between measured and predicted values (Fig. 353). Nevertheless, poor performance of the model was indicated by the cross-validation results (Table 142). The error map showed low error over the study extent (Fig. 354). The kriged surface is presented in Fig. 355.

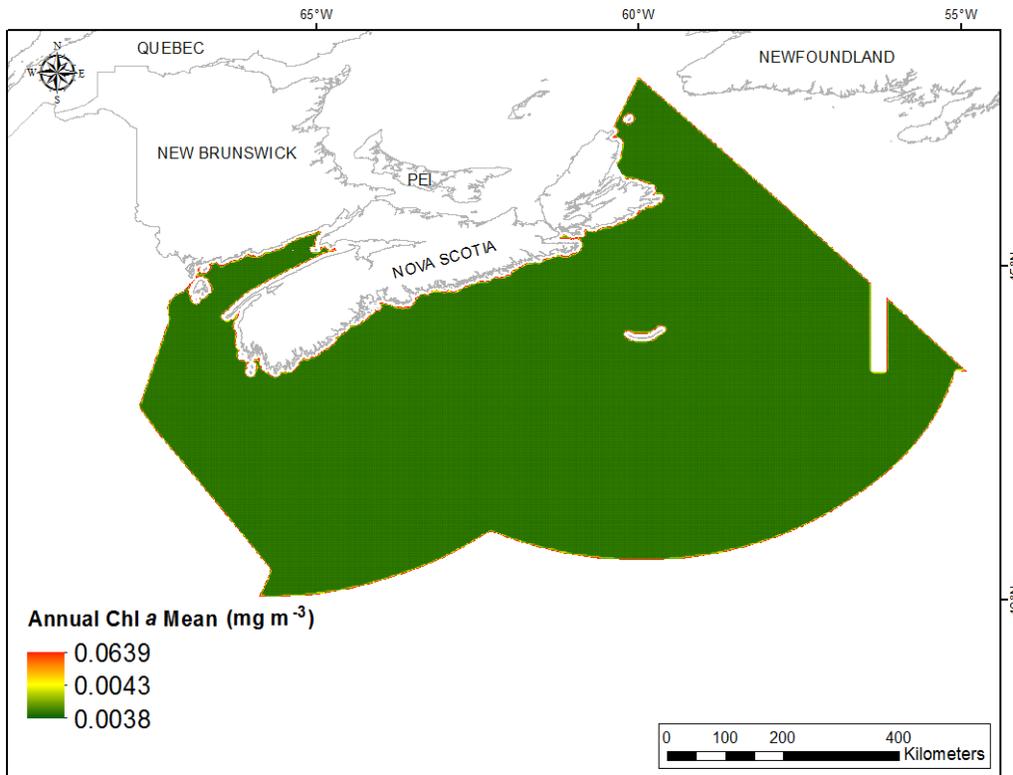

Fig. 354. Prediction standard error surface of Annual Chlorophyll *a* Mean (mg m^{-3}).

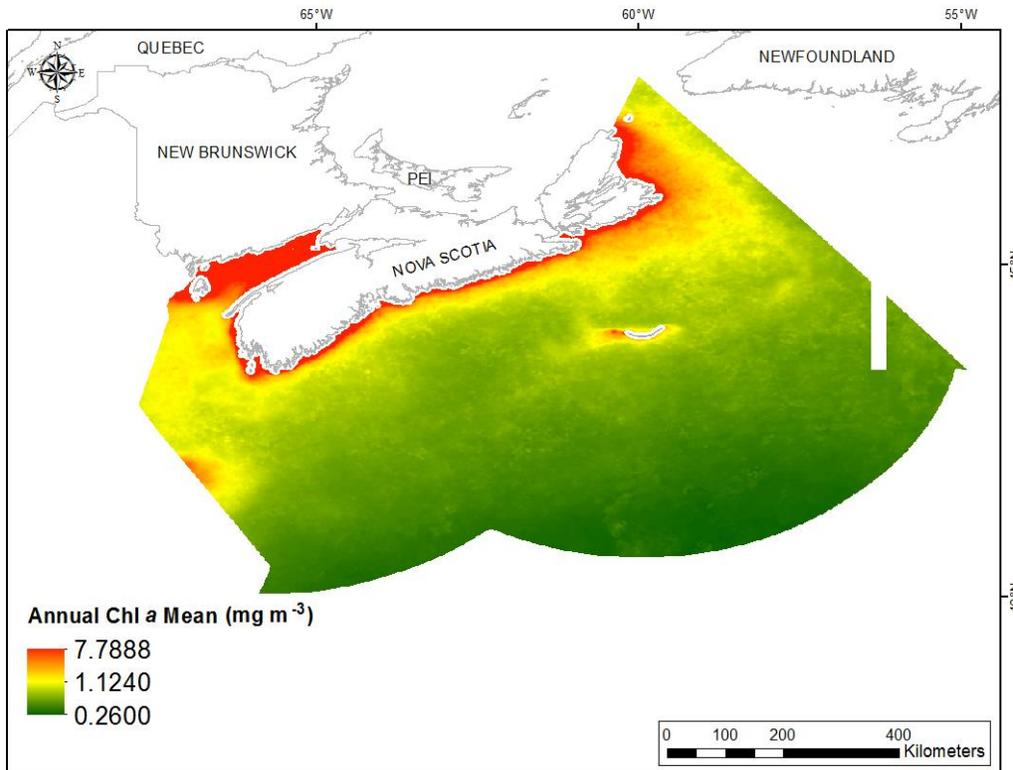

Fig. 355. Interpolated prediction surface of Annual Chlorophyll *a* Mean (mg m^{-3}).

Annual Chlorophyll *a* Minimum

This variable displayed a right-skewed, highly leptokurtic prior to interpolation (Table 143, Fig. 356). The data were higher than predicted by a normal distribution at both tails and lower than predicted at mid-values (Fig. 357). The areas of under- and over-prediction showed a very strong spatial pattern over the study extent (Fig. 357).

The semivariogram showed weak autocorrelation present in the data and the model showed a very good fit between measured and predicted values (Fig. 358). However, poor model performance was indicated by the cross-validation results (Table 144). The Standardized Root-Mean-Square Prediction Error was greater than 1 indicating that variability in the predictions has been underestimated. The error map showed low error over the study extent (Fig. 359). The kriged surface is presented in Fig. 360.

Annual Chlorophyll *a* Range

This variable displayed a right-skewed, highly leptokurtic distribution prior to interpolation (Table 147, Fig. 366). The data were higher than predicted by a normal distribution at both tails and slightly lower than predicted at mid-values (Fig. 367). The areas of under- and over-prediction showed no spatial pattern over the study extent (Fig. 367).

The semivariogram showed moderate autocorrelation present in the data and the model showed good fit between measured and predicted values (Fig. 368). However, poor model performance was indicated by the cross-validation results (Table 148). The Standardized Root-Mean-Square Prediction Error was greater than 1 indicating that variability in the predictions has been underestimated. The error map showed low error over the study extent (Fig. 369). The kriged surface is presented in Fig. 370. Negative values resulted from the right-skewed nature of the raw data (Fig. 366). Of the 326,283 raster cells in the study extent, only 1 was negative (see Table A1). This was located near the southern edge of the study extent above the abyssal plain (Fig. A6).

Primary Production

Primary production measures the rate at which atmospheric or aqueous carbon dioxide is converted to organic carbon by autotrophs (Bender et al., 1987) and relates more directly to the flux of particulate organic carbon and food supply to the seafloor than sea surface chlorophyll *a* concentration. However, as satellite-derived chlorophyll *a* is a main source of data used in the calculation of the primary production variables in this report, we expect these variables to be highly correlated.

Spring Primary Production Mean

This variable displayed a near-normal distribution prior to interpolation (Table 149, Fig. 371). The data were higher than predicted by a normal distribution at the lower range and lower than predicted at the highest and the lowest values (Fig. 372). The areas of under- and over-prediction showed no spatial pattern over the study extent (Fig. 372).

The semivariogram showed moderate autocorrelation present in the data and the model showed fair fit between measured and predicted values (Fig. 373). Good performance of the model was indicated by the cross-validation results (Table 150). The error map showed high error along the edges of the study extent (Fig. 374). The kriged surface is presented in Fig. 375.

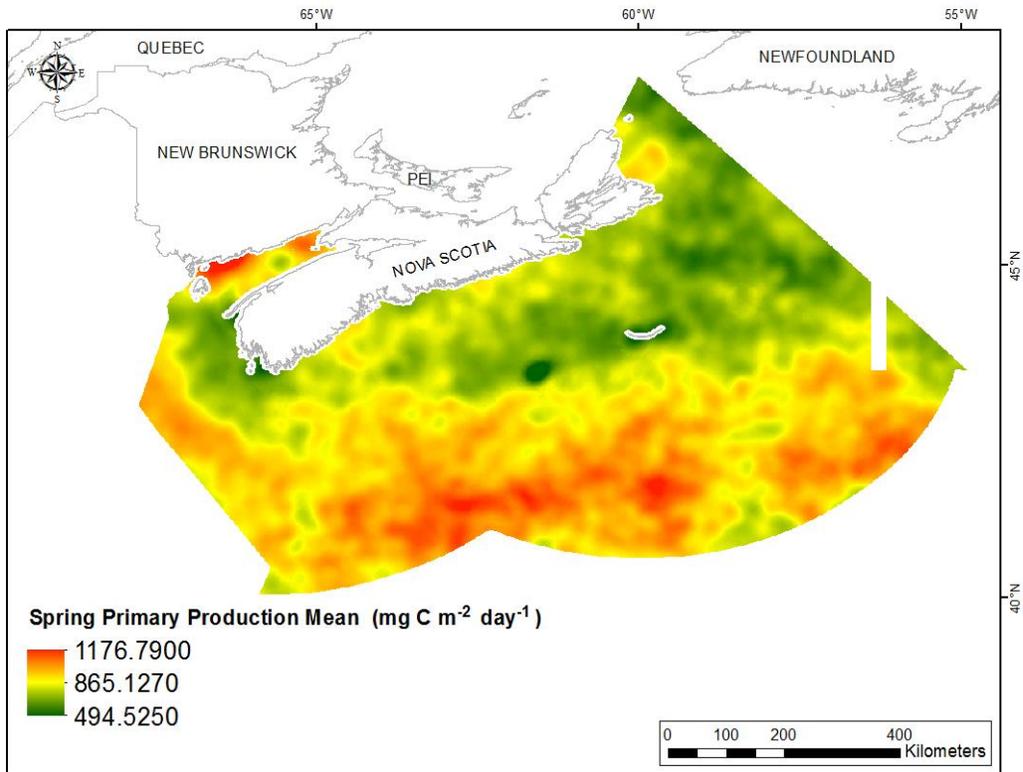

Fig. 375. Interpolated prediction surface of Spring Primary Production Mean ($\text{mg C m}^{-2} \text{ day}^{-1}$).

Spring Primary Production Minimum

This variable displayed a near-normal distribution with light leptokurtosis prior to interpolation (Table 151, Fig. 376). The data were higher than predicted by a normal distribution at both tails and slightly lower than predicted at mid-values (Fig. 377). The areas of under- and over-prediction showed no spatial pattern over the study extent (Fig. 377).

The semivariogram showed moderate autocorrelation present in the data (Fig. 378). The fit between measured and predicted values was fair (Fig. 378), with under-prediction of large values and over-prediction of small values, a property inherent to the kriging method. Good performance of the model was indicated by the cross-validation results (Table 152). The error map showed moderate error over the study extent (Fig. 379). The kriged surface is presented in Fig. 380.

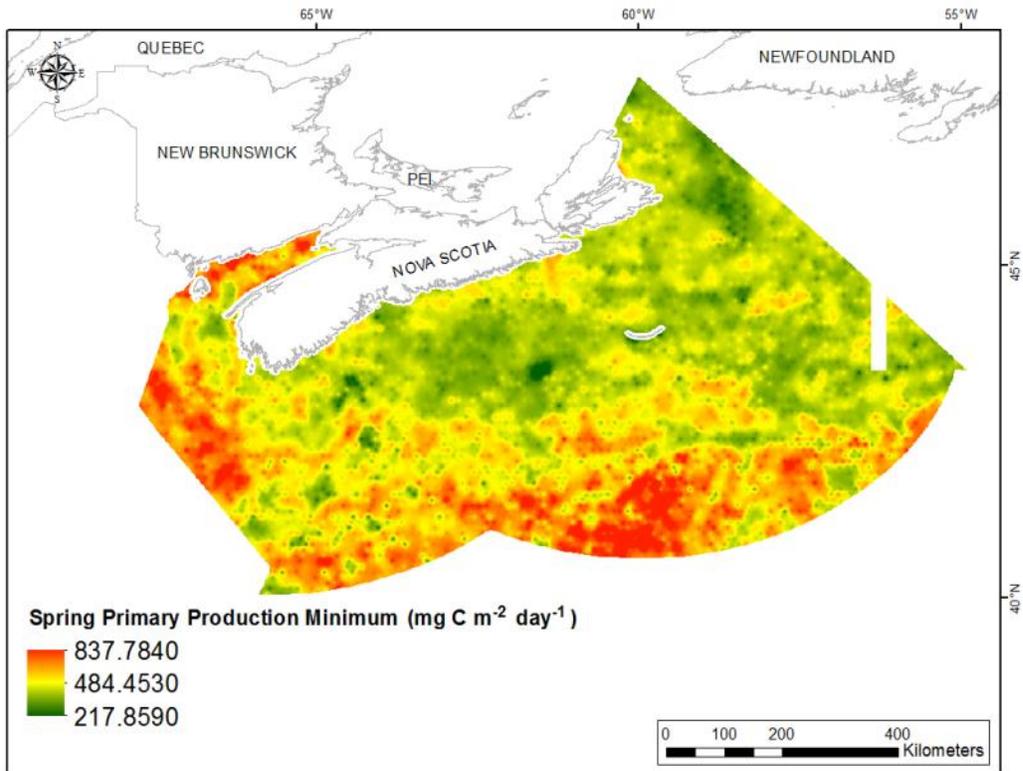

Fig. 380. Interpolated prediction surface of Spring Primary Production Minimum ($\text{mg C m}^{-2} \text{ day}^{-1}$).

Spring Primary Production Maximum

This variable displayed a negatively skewed, leptokurtic distribution with outlying data in the upper range (Table 153, Fig. 381). The data followed the 1:1 reference line in the Q-Q plot (Fig. 382) except at the extreme tails where the data were higher than predicted at the upper range and lower than predicted at the lower range. The areas of under- and over-prediction showed no spatial pattern over the study extent (Fig. 382).

The semivariogram showed moderate autocorrelation present in the data (Fig. 383). The fit between measured and predicted values was fair (Fig. 383), with under-prediction of large values and over-prediction of small values, a property inherent to the kriging method. The single large outlier was poorly predicted. Good performance of the model was indicated by the cross-validation results (Table 154). The error map showed high error along the edges of the study extent (Fig. 384). The kriged surface is presented in Fig. 385.

Spring Primary Production Range

This variable displayed a negatively skewed, leptokurtic distribution with outlying data in the upper range (Table 155, Fig. 386). The data followed the 1:1 reference line in the Q-Q plot (Fig. 387) except at the extreme tails where the data were higher than predicted at the upper range and lower than predicted at the lower range. The areas of under- and over-prediction showed no spatial pattern over the study extent (Fig. 387).

The semivariogram showed moderate autocorrelation present in the data (Fig. 388). The fit between measured and predicted values was fair (Fig. 388), with under-prediction of large values and over-prediction of small values. The single large outlier was poorly predicted. Good performance of the model was indicated by the cross-validation results (Table 156). The error map showed high error along the edges of the study extent (Fig. 389). The kriged surface is presented in Fig. 390.

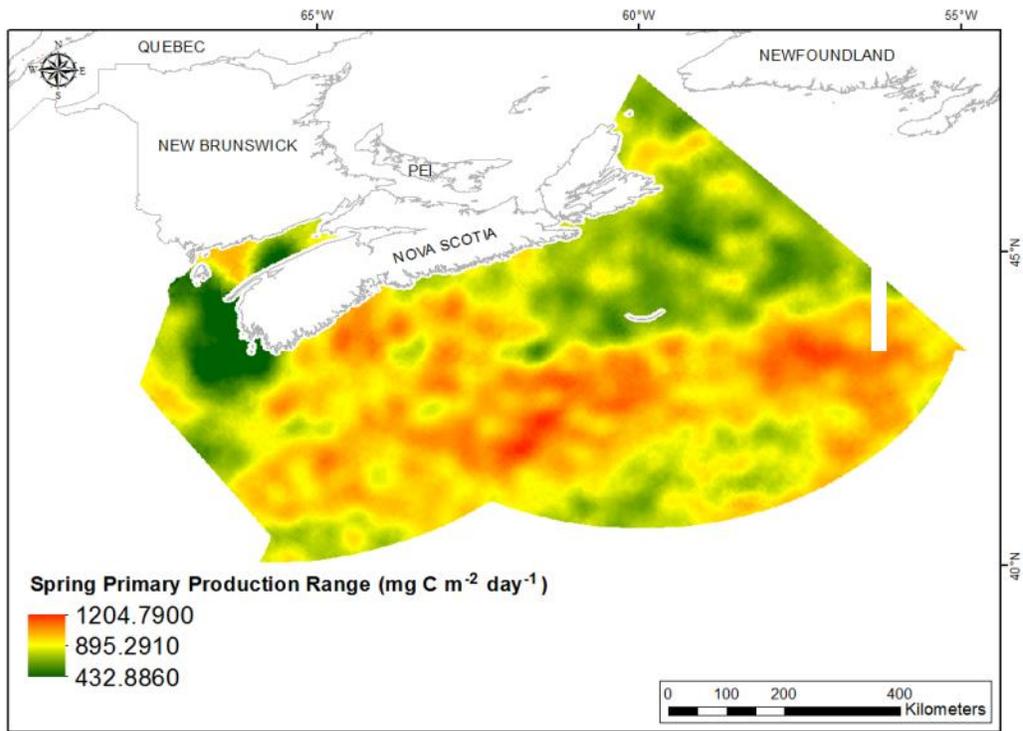

Fig. 390. Interpolated prediction surface of Spring Primary Production Range (mg C m⁻² day⁻¹).

Spring Primary Production Average Minimum

This variable displayed a near-normal distribution prior to interpolation (Table 157, Fig. 391). The data were higher than predicted by a normal distribution at low and high values however the mid-region was very well-predicted (Fig. 392). The areas of over- and under-prediction showed no spatial pattern over the study extent (Fig. 292).

The semivariogram showed weak autocorrelation present in the data (Fig. 393). The fit between measured and predicted values was fair (Fig. 393), with under-prediction of large values and over-prediction of small values. Good performance of the model was indicated by the cross-validation results (Table 158). Moderate error was predicted over the study extent (Fig. 394). The kriged surface is presented in Fig. 395.

Spring Primary Production Average Maximum

This variable displayed a slightly left-skewed, platykurtic distribution prior to interpolation (Table 159, Fig. 396). The data were lower than predicted by a normal distribution at both tails and slightly higher than predicted at lower mid-range values (Fig. 397). The areas of over-prediction showed no spatial pattern over the study extent (Fig. 397).

The semivariogram showed weak autocorrelation present in the data (Fig. 398). The fit between measured and predicted values was fair (Fig. 398), with under-prediction of large values and over-prediction of small values. Good performance of the model was indicated by the cross-validation results (Table 160). Moderate error was predicted over the study extent (Fig. 399). The kriged surface is presented in Fig. 400.

Spring Primary Production Average Range

This variable displayed a near normal distribution prior to interpolation (Table 161, Fig. 401). The data were higher than predicted by a normal distribution at the lowest values and lower than predicted at the highest values (Fig. 402). However, the mid-region was very well-predicted (Fig. 402). The areas of over-prediction showed no spatial pattern over the study extent (Fig. 402).

The semivariogram showed moderate autocorrelation present in the data (Fig. 403). The fit between measured and predicted values was fair (Fig. 403), with under-prediction of large values and over-prediction of small values. Good performance of the model was indicated by the cross-validation results (Table 162). Moderate error was predicted over the study extent (Fig. 404). The kriged surface is presented in Fig. 405.

Summer Primary Production Mean

This variable displayed a bimodal distribution prior to interpolation (Table 163, Fig. 406). The data were higher than predicted by a normal distribution at mid- and the lowest range values and lower than predicted at low and the highest range values (Fig. 407). The areas of under- and over-prediction showed a spatial pattern over the study extent (Fig. 407).

The semivariogram showed moderate autocorrelation present in the data and the model showed a good fit between measured and predicted values (Fig. 408). Good performance of the model was indicated by the cross-validation results (Table 164). The error map showed moderate error across the study extent except at the exact location of data points where it was low (Fig. 409). The kriged surface is presented in Fig. 410.

Summer Primary Production Minimum

This variable displayed a platykurtic distribution prior to interpolation (Table 165, Fig. 411). The data were higher than predicted by a normal distribution at low and upper-mid range values and lower than predicted at mid and high values (Fig. 412). The areas of under- and over-prediction showed some spatial pattern over the study extent (Fig. 412).

The semivariogram showed moderate autocorrelation present in the data and the model showed good fit between measured and predicted values (Fig. 413). Good performance was indicated by the cross-validation results (Table 166). The error map showed high error along the edges of the study extent (Fig. 414). The kriged surface is presented in Fig. 415.

Summer Primary Production Average Range

This variable displayed a right-skewed distribution prior to interpolation (Table 175, Fig. 436). The data were higher than predicted by a normal distribution at both tails (Fig. 437). No data points fell below the reference line. The areas of over-prediction showed no strong spatial pattern over the study extent (Fig. 437).

The semivariogram showed weak autocorrelation present in the data (Fig. 438). The fit between measured and predicted values was fair (Fig. 438), with under-prediction of large values and over-prediction of small values. Good performance of the model was indicated by the cross-validation statistics (Table 176). The error map showed moderate error across the study extent (Fig. 439). The kriged surface is presented in Fig. 440.

Fall Primary Production Mean

There was incomplete coverage of this variable across the study extent. Prior to interpolation, this variable displayed a slightly right-skewed, leptokurtic distribution (Table 177, Fig. 441). The data were higher than predicted by a normal distribution at mid-range and high values and slightly lower than predicted at low values (Fig. 442). The areas of under- and over-prediction showed no spatial pattern over the study extent (Fig. 442).

The semivariogram showed moderate autocorrelation present in the data (Fig. 443). The fit between measured and predicted values was fair (Fig. 443), with under-prediction of large values and over-prediction of small values. Good performance of the model was indicated by the cross-validation statistics (Table 178). The error map showed patches of high error across the study extent, particularly off Cape Breton (Fig. 444). The kriged surface is presented in Fig. 445.

Fall Primary Production Minimum

There was incomplete coverage of this variable across the study extent. Prior to interpolation, this variable displayed a slightly left-skewed, platykurtic distribution (Table 179, Fig. 446). The data were slightly lower than predicted by a normal distribution at lower mid-range and high values and slightly higher than predicted at low values (Fig. 447). The areas of under- and over-prediction showed no spatial pattern over the study extent (Fig. 447).

The semivariogram showed moderate autocorrelation present in the data (Fig. 448). The fit between measured and predicted values was fair (Fig. 448), with under-prediction of large values and over-prediction of small values. Good performance of the model was indicated by the cross-validation statistics (Table 180). The error map showed patches of high error across the study extent, particularly off Cape Breton (Fig. 449). The kriged surface is presented in Fig. 450.

Fall Primary Production Maximum

There was incomplete coverage of this variable across the study extent. Prior to interpolation, this variable displayed a slightly right-skewed, leptokurtic distribution (Table 181, Fig. 451). The data were lower than predicted by a normal distribution at mid-range values and higher than predicted at both tails (Fig. 452). The areas of under- and over-prediction showed no spatial pattern over the study extent (Fig. 452).

The semivariogram showed moderate autocorrelation present in the data (Fig. 453). The fit between measured and predicted values was fair (Fig. 453), with under-prediction of large values. Good performance of the model was indicated by the cross-validation statistics (Table 182). The error map showed patches of high error across the study extent, particularly off Cape Breton (Fig. 454). The kriged surface is presented in Fig. 455.

Fall Primary Production Range

There was incomplete coverage of this variable across the study extent. Prior to interpolation, this variable displayed a slightly right-skewed, leptokurtic distribution (Table 183, Fig. 456). The data were higher than predicted by a normal distribution at both tails, and slightly lower than predicted at mid-range values (Fig. 457). The areas of under- and over-prediction showed no spatial pattern over the study extent (Fig. 457).

The semivariogram showed moderate autocorrelation present in the data (Fig. 458). The fit between measured and predicted values was fair (Fig. 458), with under-prediction of large values and over-prediction of small values. Good performance of the model was indicated by the cross-validation statistics (Table 184). The error map showed patches of high error across the study extent, particularly off Cape Breton (Fig. 459). The kriged surface is presented in Fig. 460.

Fall Primary Production Average Minimum

There was incomplete coverage of this variable across the study extent. This variable displayed a near-normal distribution with negative skew (Table 185, Fig. 461). The data were higher than predicted by a normal distribution at both tails and lower than predicted at lower and upper mid-range values (Fig. 462). Mid-range values were well predicted. The areas of under- and over-prediction showed no spatial pattern over the study extent (Fig. 462).

The semivariogram showed weak autocorrelation present in the data (Fig. 463). The fit between measured and predicted values was fair (Fig. 463), with under-prediction of large values and over-prediction of small values. Good performance of the model was indicated by the cross-validation statistics (Table 186). The error map showed patches of high error across the study extent, particularly off Cape Breton (Fig. 464). The kriged surface is presented in Fig. 465.

Fall Primary Production Average Maximum

There was incomplete coverage of this variable across the study extent. Prior to interpolation, this variable displayed slightly right-skewed, leptokurtic distribution (Table 187, Fig. 466). The data were lower than predicted by a normal distribution at mid-range values and higher than predicted at both tails (Fig. 467). The areas of under- and over-prediction showed no spatial pattern over the study extent (Fig. 467).

The semivariogram showed moderate autocorrelation present in the data (Fig. 468). The fit between measured and predicted values was fair (Fig. 468), with under-prediction of large values and over-prediction of small values. Good performance of the model was indicated by the cross-validation statistics (Table 188). The error map showed patches of high error across the study extent, particularly off Cape Breton (Fig. 469). The kriged surface is presented in Fig. 470.

Fall Primary Production Average Range

There was incomplete coverage of this variable across the study extent. Prior to interpolation, this variable displayed right-skewed, leptokurtic distribution (Table 189, Fig. 471). The data were lower than predicted by a normal distribution at mid-range values and higher than predicted at both tails (Fig. 472). The areas of under- and over-prediction showed no spatial pattern over the study extent (Fig. 472).

The semivariogram showed moderate autocorrelation present in the data (Fig. 473). The fit between measured and predicted values was fair (Fig. 473), with under-prediction of large values and over-prediction of small values. Good performance of the model was indicated by the cross-validation statistics (Table 190). The error map showed patches of high error across the study extent, particularly off Cape Breton (Fig. 474). The kriged surface is presented in Fig. 475.

Annual Primary Production Mean

This variable displayed a right-skewed, leptokurtic distribution prior to interpolation (Table 191, Fig. 476). The data were higher than predicted by a normal distribution at high values and lower than predicted at low values however the mid-region was well-predicted (Fig. 477). The areas of under- and over-prediction showed no spatial pattern over the study extent (Fig. 477).

The semivariogram showed moderate autocorrelation present in the data (Fig. 478). The fit between measured and predicted values was fair (Fig. 478), with under-prediction of large values and over-prediction of small values. Good performance of the model was indicated by the cross-validation results (Table 192). The error map showed high error along the edges of the study extent (Fig. 479). The kriged surface is presented in Fig. 480.

Annual Primary Production Minimum

This variable displayed a right-skewed, slightly platykurtic distribution prior to interpolation (Table 193, Fig. 481). The data were higher than predicted by a normal distribution at low and high values and slightly lower than predicted at mid-values (Fig. 482). The areas of under- and over-prediction showed no spatial pattern over the study extent (Fig. 482).

The semivariogram showed moderate autocorrelation present in the data (Fig. 483). The fit between measured and predicted values was fair (Fig. 483), with under-prediction of large values and over-prediction of small values. Good performance of the model was indicated by the cross-validation results (Table 194). The error map showed high error along the edges of the study extent (Fig. 484). The kriged surface is presented in Fig. 485.

Annual Primary Production Maximum

This variable displayed a left-skewed, leptokurtic distribution with outlying data in the upper range (Table 195, Fig. 486). The data were higher than predicted by a normal distribution at the highest values and lower than predicted at the lowest values (Fig. 487) with good prediction of mid-range values (Fig. 487). The areas of under- and over-prediction showed no spatial pattern over the study extent (Fig. 487).

The semivariogram showed weak to moderate autocorrelation present in the data (Fig. 488). The fit between measured and predicted values was poor (Fig. 488), with under-prediction of large values and over-prediction of small values. The single large outlier was poorly predicted. Nonetheless good performance of the model was indicated by the cross-validation results (Table 196). The error map showed high error along the edges of the study extent (Fig. 489). The kriged surface is presented in Fig. 490.

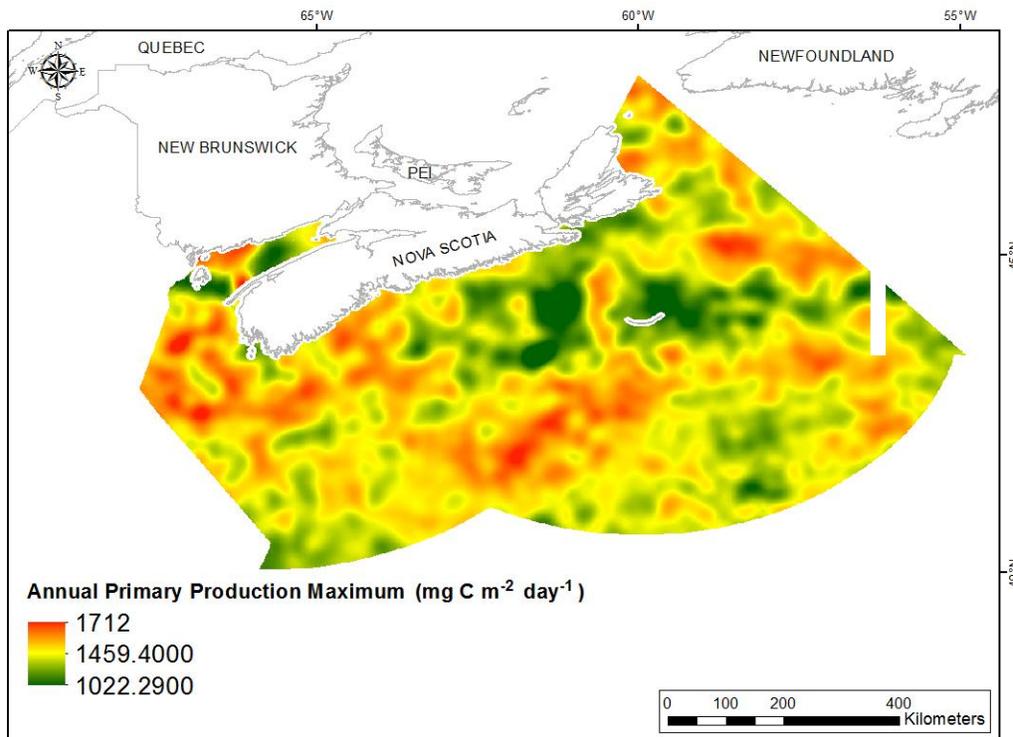

Fig. 490. Interpolated prediction surface of Annual Primary Production Maximum ($\text{mg C m}^{-2} \text{ day}^{-1}$).

Annual Primary Production Range

This variable displayed a leptokurtic distribution with outlying data in the upper range prior to interpolation (Table 197, Fig. 591). The data were higher than predicted by a normal distribution at the highest value and lower than predicted at the lowest values (Fig. 492). However, the mid-region was well-predicted. The areas of under- and over-prediction showed no spatial pattern over the study extent (Fig. 492).

The semivariogram showed weak autocorrelation present in the data and the model showed poor fit between measured and predicted values (Fig. 493). The fit between measured and predicted values was poor (Fig. 493), with under-prediction of large values and over-prediction of small values. The single large outlier was poorly predicted. Nonetheless good performance of the model was indicated by the cross-validation results (Table 198). The error map showed high error along the edges of the study extent (Fig. 494). The kriged surface is presented in Fig. 495.

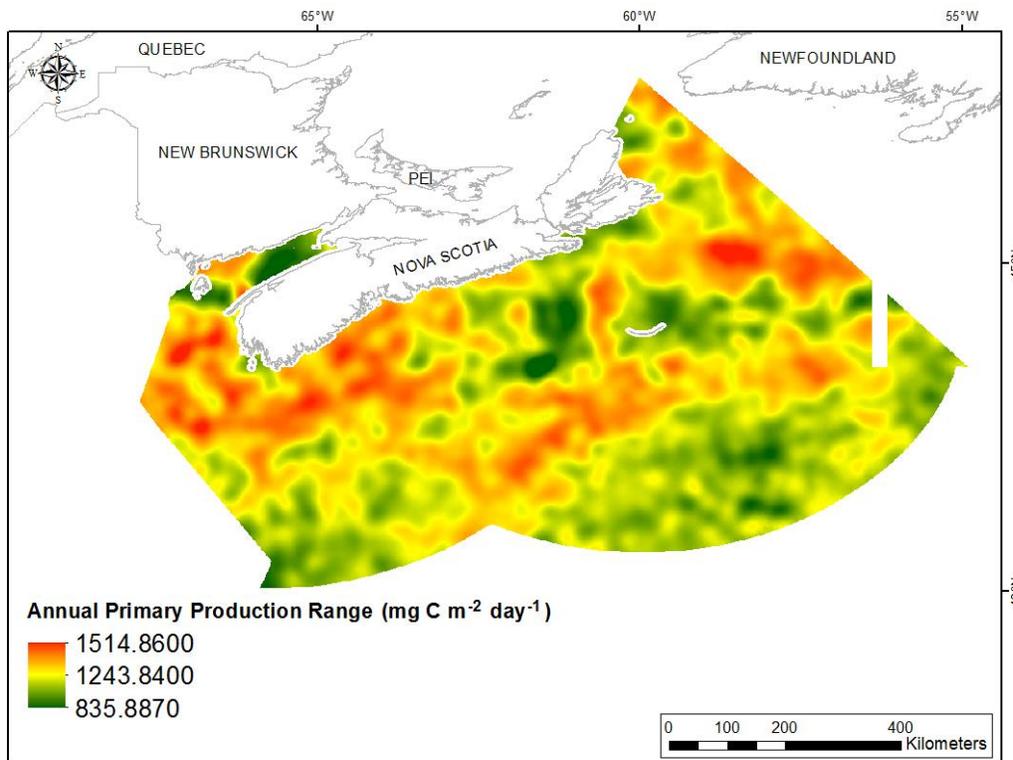

Fig. 495. Interpolated prediction surface of Annual Primary Production Range ($\text{mg C m}^{-2} \text{ day}^{-1}$).

Annual Primary Production Average Minimum

This variable displayed a leptokurtic distribution with outlying data in the upper range (Table 199, Fig. 496). The data were higher than predicted by a normal distribution at both tails, however, the mid-region was well-predicted (Fig. 497). The areas of over-prediction showed little spatial pattern over the study extent (Fig. 497).

The semivariogram showed moderate autocorrelation present in the data (Fig. 498). The model showed a poor fit between measured and predicted values (Fig. 498), with over-prediction of small values and under-prediction of large values. Nonetheless, good performance of the model was indicated by the cross-validation results (Table 200). The error map showed high error along the edges of the study extent (Fig. 499). The kriged surface is presented in Fig. 500.

Annual Primary Production Average Maximum

This variable displayed a near-normal distribution with slight negative skew and leptokurtosis prior to interpolation (Table 201, Fig. 501). The data were lower than predicted by a normal distribution at both tails, however the mid-region was well-predicted (Fig. 502). The areas of under-prediction showed no spatial pattern over the study extent (Fig. 502).

The semivariogram showed moderate autocorrelation present in the data (Fig. 503). The model showed a poor fit between measured and predicted values (Fig. 503), with over-prediction of small values and under-prediction of large values. Nonetheless, good performance of the model was indicated by the cross-validation results (Table 202). The error map showed high error along the edges of the study extent (Fig. 504). The kriged surface is presented in Fig. 505.

Annual Primary Production Average Range

This variable displayed a near-normal distribution with slight negative skew prior to interpolation (Table 203, Fig. 506). The data were lower than predicted by a normal distribution at both tails, however the mid-values were well predicted (Fig. 507). The areas of under-prediction showed no spatial pattern over the study extent (Fig. 507).

The semivariogram showed moderate autocorrelation present in the data (Fig. 508). The model showed a poor fit between measured and predicted values (Fig. 508), with over-prediction of small values and under-prediction of large values. Nonetheless, good performance of the model was indicated by the cross-validation results (Table 204). The error map showed high error along the edges of the study extent (Fig. 509). The kriged surface is presented in Fig. 510.

Dissolved Oxygen

Dissolved oxygen affects the distribution of marine animals, and is produced in the marine environment. The ratio of dissolved oxygen to carbon is used to estimate net primary production during a bloom period (Queste et al., 2015). Generally, as water stratification develops in the spring, nitrate, phosphate, and silicate nutrients are consumed and drawn down to deeper water by phytoplankton and remain low throughout the rest of the year, while dissolved oxygen decreases (Manasrah et al., 2006).

Dissolved Oxygen

This variable displayed a bimodal distribution prior to interpolation (Table 205, Fig. 511). The data were higher than predicted by a normal distribution at the lowest and upper mid-range values, and lower than the reference line at mid-values (Fig. 512). The areas of under- and over-prediction showed no spatial pattern over the study extent (Fig. 512).

The semivariogram showed weak autocorrelation present in the data (Fig. 513). The model showed poor fit between measured and predicted values (Fig. 513), with over-prediction of low values and under-prediction of high values. Poor model performance was also indicated by the cross-validation statistics (Table 206). The error map showed a highly discontinuous and patchy pattern over the study extent with low error at the location of data observations (Fig. 514). The kriged surface, which is also patchy and discontinuous, is presented in Fig. 515.

APPENDIX I - Summary of Variables with Negative Values in the Interpolated Prediction Surface Resulting from Ordinary Kriging

Appendix 1 shows a map of each of the seven variables with negative values resulting in the prediction surfaces after spatial interpolation using ordinary kriging. The location of the negative values is highlighted in blue. The data distribution prior to modeling and the numbers of cells with negative values for each variable is presented in Table A1. Negative values associated with temperature and salinity were found along the continental slope.

Table A1. Summary of environmental variables with negative prediction values resulting from ordinary kriging.

Variable	Negative values in input	Data distribution	Total number of cells	Cells with negative values	Range of negative values
Bottom Temperature Range	No	Right-skewed	326,283	1970	-0.78 to -2.43×10^{-6}
Bottom Temperature Average Range	No	Right-skewed, single large outlier	326,283	5470	-0.68 to -5.26×10^{-6}
Bottom Salinity Range	No	Right-skewed, single large outlier	326,283	4032	-0.18 to -2.83×10^{-6}
Bottom Salinity Average Range	No	Right-skewed, single large outlier	326,283	11390	-0.13 to -1.39×10^{-6}
Spring Chlorophyll <i>a</i> Range	No	Right-skewed	326,283	2	-0.06, -0.03
Annual Chlorophyll <i>a</i> Range	No	Right-skewed; outliers	326,283	1	-0.02
