## Southeast Coast Newfoundland Herring 1985 Assessment

by
J. P. Wheeler and E. L. Dalley

Science Branch
Department of Fisheries and Oceans
P. 0. Box 5667

St. John's, Newfoundland A1C 5X1

1 This series documents the scientific basis for fisheries management advice in Atlantic Canada. As such, it addresses the issues of the day in the time frames required and the Research Documents it contains are not intended as definitive statements on the subjects addressed but rather as progress reports on ongoing investigations.

Research Documents are produced in the official language in which they are provided to the Secretariat by the author.

1 Cette série documente les bases scientifiques des conseils de gestion des pêches sur la côte atlantique du Canada. Comme telle, elle couvre les problèmes actuels selon les échéanciers voulus et les Documents de recherche qu'elle contient ne doivent pas être considérés comme des énoncés finals sur les sujets traités mais plutôt comme des rapports d'étape sur les études en cours.

Les Documents de recherche sont publiés dans la langue officielle utilisée par les auteurs dans le manuscrit envoyé au secrētariat.

#### Abstract

Data analysis for 1985 are presented for the two southeast coast Newfoundland nerring stock complexes: 1) St. Mary's-Placentia Bays and 2) Fortune Bay. Landings from the commercial fishery, which was restricted to gillnets only, were less than 200 t. In St. Mary's-Placentia Bays the 11+ age group and the 1979 year-class were dominant in the commercial fishery. In Fortune Bay the fishery was dominated by the 1979, 1980, and 1982 year-classes. Samples from the acoustic purse seine survey in St. Mary's-Placentia Bays were dominated by the 1982 year-class; no samples were available from Fortune Bay. The research gillnet samples in St. Mary's-Placentia Bays were dominated by 11+ age groups followed by the 1982 and 1979 year-classes. In Fortune Bay research gillnet samples, the 1980 year-class was most abundant followed by the 1979 year-class and the $11+$ age group. No catch rate data were available from the commercial fishery. Catch rates from the research gillnet program showed an increase from 1984 to 1985. Biomass estimates and population numbers at age were calculated from the acoustic purse seine surveys. Projections were made to 1987 assuming a fixed catch in 1986 and illustrative projections were made to 1992.

#### Abstract

Rēsumé Des analyses des donnēes de 1985 sont prēsentēes pour les deux complexes de stocks de harengs de la côte sud-ouest de Terre-Neuve: 1) baies St. Mary's et Placentia et 2) baie Fortune. Les dēbarquements de la pêche commerciale, limitée exclusivement au filet maillant, ētaient inférieurs à 200 t. Dans les baies St-Mary's et Placentia le groupe d'âges $11+$ et la classe d'âge de 1979 dominaient dans les captures commerciales. Dans la baie Fortune les classes d'âges de 1979, de 1980 et de 1982 dominaient. Les relevés au filet coulissant acoustique dans les baies St. Mary's et Placentia indiquent que la classe d'âge de 1982 domine; aucun ēchantillon provenant de la baie Fortune n'était disponible. Les échantillons prēlevēs au filet maillant dans les baies St. Mary's et Placentia étaient dominés par les groupes d'âges $11+$ suivis des classes d'âge de 1982 et de 1979. Dans les échantillons recueillis au filet maillant dans la baie Fortune, la classe d'âge de 1980 était la plus abondante et elle était suivie de la classe d'âge de 1979 et du groupe d'âge $11+$. Aucune donnēe sur les taux de capture pour la pêche commerciale n'était disponible. Les taux de capture dans le cadre du programme de recherche au filet maillant indiquent un accroissement de 1984 à 1985. Les estimations de la biomasse et des populations en fonction de l'âge ont été calculées à partir des relevēs au filet coulissant acoustique. On a établi des projections jusqu'en 1987 en supposant un taux de capture fixe en 1986 et des projections explicatives jusqu'en 1992.

Introduction
A. Description of the Fishery:

In 1985, there was a spring and fall herring fishery in southeast Newfoundland which was restricted to gillnets only. The spring component allowed 400 t in St. Mary's-Placentia Bays and 200 t in Fortune Bay. It commenced April 1 and ended June 15. The fall fishery, which allowed 200 t in St. Mary's-Placentia Bays and 100 t in Fortune Bay, commenced October 1 and continued until December 31.
B. Nominal Catches:

TAC's and landings ( $x 103 \mathrm{t}$ ) from the fishery are listed below for 1978-85.

|  |  | 1978 | 1979 | 1980 | 1981 | 1982 | 1983 | 1984 | 1985 |
| :--- | :--- | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: |
| SMB-PB |  |  |  |  |  |  |  |  |  |
|  |  |  |  |  |  |  |  |  |  |
|  | Nominal catch | 3527 | 3600 | 2500 | 1200 | 0 | 0 | 0 | 600 |
| FB | TAC | 1000 | 1000 | 1000 | 200 | 0 | 0 | 0 | 300 |
|  | Nominal catch | 999 | 1195 | 451 | 67 | 22 | 15 | 21 | 441 |

1provisional
C. Anecdotal Information:

As in past assessments, the stock complexes considered are:

1) St. Mary's-Placentia Bays (3Lg and 3PSc) and 2) Fortune Bay (3PSn) (Fig. 1).

Annual average landings from the southeast coast herring stocks peaked around $30,000 \mathrm{t}$ between 1945-50 and declined to an average of 3450 t from 1958 to 1962. Landings increased in 1968 to $21,900 \mathrm{t}$ with the introduction of the purse seine fishery but have declined since then. Quota regulations were first placed on purse seiners in 1973 and on all other gear types in 1980. The purse seine fishery was closed in 1981; the ringnet fishery was closed in 1982. The bar seine fishery was closed in Fortune Bay in 1982 and in St. Mary's-Placentia Bays in 1983. The commercial gillnet fishery was closed from 1982-84 except for fixed gear bait permits and by-catches from the capelin and mackerel fishery. Landings, by gear, since quota regulation, are shown in Table 1 for St. Mary's-Placentia Bays and in Table 2 for Fortune Bay.

INPUT DATA
A. Biological Sampling:

The number of herring sampled in 1985, from the commercial fishery and research programs, was 3187 (Table 3). This ends a trend set in recent years
towards increased sampling with $19 \%$ fewer fish being sampled in 1985 than in 1984. However, when apportioned by stock area, month and gear type (Table 4), samples were available for $90 \%$ of the comercial catch. Samples were collected randomly and all fish sampled were measured and aged.

Mean weights at age (TaDle 5) for 1985 were derived from samples collected from January to June using both commercial and research samples.
B. Commercial Fishery Data:

Commercial catch-at-age data (Tables 6 and 7) were generated by applying age compositions from the appropriate commercial samples to landings. Where no commercial samples were available, catch-at-age data were generated using research samples collected from commercial mesh size ( $21 / 2-23 / 4^{\prime \prime}$ ) gillnets. As in past years, the catch matrix was derived for spring spawners only. The values for 1984 and 1985 are preliminary as final catch statistics were not available.

In St. Mary's-Placentia Bays the 11+ age groups were dominant followed by the 1979 year-class. This is similar to the catch structure in 1983 as opposed to 1984 when the 1979 year-class was dominant (Fig. 2). The proportion of fall spawners renained high ( $48.7 \%$ ) particularly in the younger age groups. The 1982 year-class contributed only marginally (about $3 \%$ ) to the commercial catch of spring spawners.

In Fortune Bay the age compositions in the commercial fishery were slightly different and for the first year since 1982 the 11+ age groups were not dominant (Fig. 2). The 1980 year-class was the most dominant, followed by the 1979 and 1982 year-classes. The overall proportion of fall spawners was approximately $40 \%$. The 1982 year-class, predominated by spring spawners, contributed $33 \%$ to the 1985 fishery, a higher percentage than in any other Newfoundland stock area. This was the first year that the 1982 year-class was caught in the commercial fishery on any of the stocks.

No commercial catch rate data were available in 1985.
C. Research Survey Data:
i. Acoustic Purse Seine Survey:

In 1985, for the third consecutive year, an acoustic purse seine survey was carried out on the two stock complexes. The survey was conducted during March-April 1986 commencing in Fortune Bay and terminating in St. Mary's Bay. Two vessels were used, the research vessel MARINUS and a chartered commercial ringnet vessel. Survey design and data collection were similar to that described for the Newfoundland east coast survey (Wheeler et al. 1986). The cruise tracks and set locations for both vessels are shown in Appendices 1-7. During the survey 80 schools were measured (horizontal and vertical dimensions) over a cruise track of 2380 km during 560 vessel survey hours (Table 8).

There were nine purse seine sets during the survey, two in Fortune Bay, five in Placentia Bay, and none in St. Mary's Bay (Appendix 8). Only two sets were successful, both in Placentia Bay. In these sets, spring spawners predominated constituting about $74 \%$ of the catch. The 1982 year-class made up approximately 75\% of the catch (Fig. 3) with the 1981 and 1979 year-classes being second and third in abundance in the catches.

Anchor tags were applied to 1000 nerring ( $75 \% 1982$ year-class) at each of the two successful set locations (Appendix 9) to further elucidate herring migratory patterns.

## ii. Research Gillnet Program:

The research gillnet program, initiated in 1982, was continued for the fourth consecutive year on the southeast coast stocks during the spring of 1985 (April-May). Six southeast coast fishermen, each at the same location as in 1984, (Fig. 1) were contracted to fish a fleet of five gillnets (mesh sizes $2^{\prime \prime}, 21 / 4^{\prime \prime}, 21 / 2^{\prime \prime}, 23 / 4^{\prime \prime}$, and $3^{\prime \prime}$ ), maintain an accurate daily log record of catches, and to collect and freeze samples of their catch.

The age compositions of the research gillnet catches (Fig. 4 and Appendices 10-11) were calculated by applying age distributions of samples taken during the month, normally at four-day intervals, to catches during the interval and then combining these interval age distributions to obtain one for the entire month. The spawning type composition of these catches in St. Mary's-Placentia Bays was approximately $50 \%$ autumn and $50 \%$ spring spawners, similar to that of 1984. The 1982 year-class constituted less than $1 \%$ of total number of autumn spawners but $41 \%$ of the total number of spring spawners (Fig. 4). Overall, it was the dominant year-class, representing $22 \%$ of the catch. The second largest proportion of the catch was the 11+ age groups followed by the 1979 year-class.

In Fortune Bay, the 1980 year-class was most abundant followed by the 1979 year-class and the 11+ age group. Spring spawners constituted 73\% of the research gillnet catch. The 1982 year-class represented less than $0.1 \%$ of the total number of autumn spawners and approximately $3 \%$ of the total catch of spring spawners. For the combined spawning groups, the 1982 year-class represented $2.3 \%$ of the catch by numbers.

As in previous years, two catch-per-unit-effort indices were calculated from the research gillnet program: 1) number of herring caught per fishing day and 2) number of herring caught per days nauled (Tables 9 and 10). The numbers in these tables vary slightly from those presented last year (Wheeler and Dalley 1985) due to recent computerization and standardization of technique of the time series for the different areas. Catch/days fished was higher in 1985 than in 1984 for two of the four locations in St. Mary's-Placentia Bays (Table 9) and approximately $12 \%$ higher for all four locations combined. In Fortune Bay, the catch/days fished was higher in both locations (Table 10). The catch rate in Fortune Bay was over three times higher in 1985 than in 1984.

## D. Estimation of Parameters:

In determination of partial recruitment rates (TaDle 11) attempts were made to empirically assess the younger age groups, particularly the 1982 year-class. The population numbers at age, derived from the acoustic purse seine survey were compared with the commercial catch at age and the ratios that were derived were normalized to give partial recruitment patterns.

Instantaneous total mortality estimates (Paloheimo 1961) were calculated for ages $4+$ for each of the research gillnet catch rate series (Tables 12-13). Age 4+ was chosen after examination of the catch-at-age data from the research gillnet program (Appendices 10-11) and the mesh selectivity of the various sized nets. From these data it appeared that full recruitment to the research gillnets occurred at age 4+. It was impossible to discern any trends in $Z$ value due to the variability within the data.

ASSESSMENT RESULTS
A. Biomass Calculation from Acoustic Survey:

The survey was designed such that each of the two vessels covered a separate cruise track, primarily within the 90 m contour. Only those times when the vessel was actively searching were included in estimating the length of the cruise track. Accurate records of vessel speed were kept for this purpose. The cruise track width was estimated as the lateral distance swept by the sonar while searching $(0.304 \mathrm{~km})$. It was therefore possible to estimate the square area surveyed (km$\left.)^{2}\right)$ within each stock area.

The vessel used its sonar to locate schools within the cruise track. Single line transects of each school would then be marked on the sounder paper. Horizontal and vertical dimensions of each school were subsequently measured. School depth was measured directly from the sounder scale; the horizontal dimension was converted from " mm " on the sounder to meters by relating sounder paper speed ( $\mathrm{sec} / \mathrm{mm}$ ) to vessel speed ( $\mathrm{m} / \mathrm{sec}$ ). The number of schools recorded on the sounder was considered to be a conservative estimate as not all schools observed by sonar within the cruise track were recorded on the sounder.

During the 1984 acoustic purse seine survey, and again in 1985, a relationship was calculated (Fig. 5) between cross-sectional area of schools ( $\mathrm{m}^{2}$ ) and weight per school ( kg ) as visually estimated from purse seine sets in shallow water ( $<30 \mathrm{~m}$ ) where it was considered that the entire school had been caught. The relationship between school area and school size was applied to each of the schools measured during the survey to obtain an estimate of tons observed within each bay (Table 14). Tons per $\mathrm{km}^{2}$ surveyed were then calculated. These density estimates were prorated by areal expansion to give biomass estimates within the 90 m contour, considered to be the extent of stock range. Since a number of schools were observed outside the 90 m contour, these biomass estimates were considered to be conservative.

Prior to the acoustic survey, each stock area was divided into smaller subareas or grids (Fig. 6). The observed biomass was calculated for each of these grids. Ideally, a biomass estimate within the 90 m contour should be calculated for each of these grids and then these individual estimates combined to determine stock biomass. However, an accurate estimation of stock area in each grid has not yet been calculated and therefore the biomass has not been apportioned.

In calculating numbers at age, the results from the 1985 acoustic survey in Fortune Bay were analyzed and estimates were weighted by the observed biomass within each of the sampled grids (Table 15). The observed biomass was apportioned into spring and autumn spawning components based on percentages within the purse seine samples. The observed biomass was converted to numbers by applying the mean sample weight. The total observed numbers were apportioned into numbers at age by the age composition of the sample. The observed numbers at age within each grid were combined and adjusted to include those grids in which no samples were taken. This provided predicted numbers at age within the cruise track which in turn were adjusted to give stock numbers at age within the 90 m contour. This was not done in 1986 as no samples were collected during the purse seine survey in Fortune Bay. Similarly, no samples were collected in St. Mary's-Placentia Bays in 1985. In 1986, samples were collected from one grid only in St. Mary's-Placentia Bays and age compositions from these samples were converted to stock numbers at age for all grids combined (Table 16). Population numbers at age for both stock areas, 1985 and 1986, are summarized in Table 17.

As no samples were availadle for Fortune Bay from the 1986 surveys, the 1985 population age structure was projected ahead one year and applied to the 1986 biomass estimate. For Fortune Bay, the mean of the estimates of the 1982 year-class from the 1985 and 1986 surveys was used as a minimum estimate of the population size for projections. Similarly, the estimate of the 1982 year-class from the 1986 survey in St. Mary's-Placentia Bays was used to project to 1987.

There are several sources of uncertainty in the calculation of stock biomass from the purse seine surveys which may produce either negative or positive biases in the results. These will have to be examined in more detail prior to the next assessment.

The relationship between cross-sectional areas of schools and weight per school assumes that the single line transect is through the widest lateral dimension of the school and that there is symetry to the school. For larger schools, it is difficult to ensure that the school is crossed on its widest axis. The impact of this when determining the relationship is uncertain; however, the relationship (Fig. 5), as derived, suggests that the weight of larger schools may be underestimated.

The cruise track width may be underestimated as schools which are detected and measured at the outermost lateral edge of the track would increase the effective width of the search pattern. The effect of changing vessel course to measure these schools is uncertain, as schools on the original course may be undetected.

It is also difficult to determine the effect of calculating population age compositions using the overall stock area estimate rather than from a sumation of grid biomasses as the effect depends on whether there are different densities of herring in larger or smaller grids.
B. Cohort Analysis:

Cohort analysis was not conducted for these stocks because reliable estimates of partial recruitment values and terminal fishing mortality could not be calculated.

## PROGNOSIS

A. Catch Projections:

The population numbers for the 1982 year-class calculated from the acoustic purse seine survey were used to project 1987 numbers assuming a catch in 1986 of 2100 t in St. Mary's-Placentia Bays and 700 t in Fortune Bay. These catches were assumed reasonable as they form the basis of the 1986 Herring Management Plan and may represent maximum catches due to poor market conditions. The population numbers used to initiate the projections in 1986 were corrected for natural mortality from the time of the acoustic survey to the deginning of 1986. Mean weights at age were from samples collected in 1985 (Table 5). Natural mortality was assumed to be 0.20 and $F_{0} .1$ to be 0.30 . Recruitment at age 2 was assumed to be zero. The following partial recruitment pattern, based upon a nistorical combined purse seine and gillnet fishery (Winters and Moores 1977), was used in the projection.

| Age | 2 | 3 | 4 | $5+$ |
| :---: | :---: | :---: | :---: | :---: |
| PR | 0.10 | 0.35 | 0.60 | 1.00 |

The results of the projections are as follows:

St. Mary's-Placentia Bays
Fortune Bay
2+ Biomass ( $t$ )
10,746
10,149
Catch (t)
2,550
2,400
Illustrative projections have been made to 1992 to show the effect of reduced fishing mortality ( $F=0.20$ ) and constant annual catches. The same population numbers, mean weight at age, recruitment values and partial recruitment pattern as described above were used. Since these herring stocks are near the northern end of their range, stock recruitment tends to be sporadic, 14 years between the 1968 and 1982 year-classes. To help compensate for this sporadic recruitment, projections have been made assuming two levels of fishing mortality, $F=0.30$ and $\mathrm{F}=0.20$. Projections have also been made to illustrate the effect of implementing different arbitrary annual catch levels.

The results for St. Mary's-Placentia Bays are as follows:

| Year | $F=0.30$ |  | $F=0.20$ |  | $C=1000 \mathrm{t}$ |  | $C=2000 \mathrm{t}$ |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | 5+biomass | Catch | 5+biomass | Catcn | 5+biomass | $\mathrm{F}_{5}{ }^{+}$ | 5+biomass | $\mathrm{F}_{5}{ }^{+}$ |
| 1987 | 10,700 | 2,600 | 10,700 | 1,800 | 10,700 | 0.11 | 10,700 | 0.23 |
| 1988 | 7,600 | 1,800 | 8,400 | 1,400 | 9,020 | 0.13 | 8,200 | 0.31 |
| 1989 | 5,200 | 1,200 | 6,300 | 1,000 | 7,500 | 0.16 | 5,500 | 0.51 |
| 1990 | 3,300 | 800 | 4,500 | 700 | 5,500 | 0.22 | 2,850 | 1.42 |
| 1991 | 2,100 | 500 | 3,100 | 500 | 3,800 | 0.35 |  |  |
| 1992 | 1,400 | 300 | 2,300 | 400 | 2,400 | 0.60 | - |  |

The results for Fortune Bay are as follows:

| Year | $F=0.30$ |  | $F=0.20$ |  | $C=1000 \mathrm{t}$ |  | $C=2000 \mathrm{t}$ |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | 5+biomass | Catch | 5+biomass | Catch | 5+biomass | $\mathrm{F}_{5}{ }^{+}$ | 5+biomass | $\mathrm{F}_{5}{ }^{+}$ |
| 1987 | 10,100 | 2,400 | 10,100 | 1,700 | 10,100 | 0.18 | 10,100 | 0.12 |
| 1988 | 7,000 | 1,700 | 7,800 | 1,300 | 8,000 | 0.23 | 8,500 | 0.14 |
| 1989 | 4,700 | 1,100 | 5,800 | 900 | 5,700 | 0.34 | 6,700 | 0.18 |
| 1990 | 3,300 | 800 | 4,500 | 700 | 3,900 | 0.55 | 5,300 | 0.23 |
| 1991 | 2,000 | 500 | 3,000 | 500 | 1,800 | 2.05 | 3,500 | 0.38 |
| 1992 | 1,300 | 300 | 2,100 | 300 | - | - | 2,000 | 0.77 |

B. Management Implications:

Similar to last year, projections have been based entirely upon population estimates derived from the acoustic survey. This technique shows excellent potential as it is independent of the commercial fishery and provides estimates of year-class size prior to their recruitment to the fishery. Although refinements have been made from last year, the estimates are still very preliminary and further analysis is required, in particular with regard to the relationship between school size and school weight and other sources of uncertainty. A comparative survey, involving more sophisticated hydroacoustic techniques to estimate school size and density, would provide more information on this relationship.

The short term future of the Newfoundland nerring stocks looks secure with the recruitment of the 1982 year-class. The long term future depends both upon management practices and recruitment success.

## Acknowledgments

We would like to thank all technical staff who were involved in the herring research program, M. F. Dawson who administered the research gillnet program in an excellent manner, P. J. Williams who provided our best sampling coverage ever, to all our samplers, and to our typist, M. Y. Hynes.
