**Stock Assessment for the 1986
Cod Population in 4X**

by

¹This series documents the scientific basis for fisheries management advice in Atlantic Canada. As such, it addresses the issues of the day in the time frames required, and the Research Documents it contains are not intended as definitive statements on the subjects addressed but rather as progress reports on ongoing investigations.

Research Documents are produced in the official language in which they are provided to the Secretariat by the author.

¹Cette série documente les bases scientifiques des conseils de gestion des pêches sur la côte atlantique du Canada. Comme telle, elle couvre les problèmes actuels selon les échéanciers voulus et les Documents de recherche qu'elle contient ne doivent pas être considérés comme des énoncés finals sur les sujets traités mais plutôt comme des rapports d'étape sur les études en cours.

Les Documents de recherche sont publiés dans la langue officielle utilisée par les auteurs dans le manuscrit envoyé au secrétariat.

Abstract

For the fourth consecutive year, the TAC for 4X cod was not caught; the 1986 nominal catch was 19,912 t. Mobile gear <65' effectively reached their allocation, but other gear categories fell far short. Longline effort continued its decline of recent years. Interpretation of commercial catch rates was complicated by misreporting and the multispecies nature of the fishery. Nevertheless, catch rates for both otter trawlers and longliners have declined substantially since the late 1970s. In addition, all research vessel indices of stock abundance and biomass declined in 1986. Calibration of the cohort analysis ages 4-6 against RV ages 4-6 indicated a terminal fishing mortality of 0.55. This estimate is consistent with the time series of fully-recruited fishing mortalities and the observed mean weight in the catch. SPA biomass has declined in recent years and has now reached a 27-year low. Given the low stock biomass and the absence of strong recruiting year-classes, consideration may have to be given to more serious stock preservation measures if abundance indices continue their decline in 1987. If the 1987 TAC of 17,500 t is caught, the 1988 catch under the 50% rule would be 14,000 t.

Résumé

Pour la quatrième année consécutive, le TPA pour la morue dans 4X n'a pas été atteint; les prises nominales de 1986 ont été de 19 912 t. Les quotas pour les engins mobiles < 65 pied ont été effectivement atteints, mais cela a été loin d'être le cas pour les autres catégories d'engins. L'effort de pêche à la palangre a poursuivi son déclin des dernières années. L'interprétation des taux de prises commerciales a été compliquée par les déclarations inexactes et par la diversité des espèces pêchées. Néanmoins, les taux de prises autant des chalutiers que des palangriers ont fléchi sensiblement depuis la fin des années 1970. De plus, tous les indices d'abondance des stocks et de biomasse des navires de recherche ont chuté en 1986. L'étalonnage des âges 4-6 de l'analyse des cohortes en fonction des âges 4-6 de NR a révélé une mortalité par pêche de la dernière année de 0,55. Cette estimation est en accord avec la série chronologique de mortalité par pêche de plein recrutement et le poids moyen observé dans la capture. L'ASP a révélé que la biomasse a diminué au cours des dernières années et atteint maintenant son plus bas niveau depuis 27 ans. Vu la faible quantité de biomasse et l'absence de classes d'âge de recrutement élevé, il se peut qu'il faille envisager des mesures plus strictes de protection des stocks si les indices d'abondance continuent de chuter en 1987. Si le TPA de 1987 de 17 500 t est capturé, les prises de 1988 d'après la règle de 50 % seraient de 14 000 t.

Nominal Catches

Historically, the cod fishery in Division 4X (Figure 1) has been prosecuted by the Canadian inshore fleet. Between 1947 and 1961, nominal catches for the Division averaged 15,000 t, with less than 3,000 t estimated as having come from the offshore grounds. The introduction of large foreign trawlers in 1962 resulted in a rapid increase in catches, which peaked at 35,500 t in 1968 (Table 1). Imposition of quotas on 4X haddock by ICNAF in 1970 substantially reduced cod catches (to approximately 22,000 t), emphasizing the by-catch nature of many cod catches. Since 1976, the fishery has been essentially 100% Canadian and catches increased to almost 32,000 t; however, there has been a marked decline in catches since 1982 (Figure 3). The 1986 nominal catch was 19,912 t.

None of the gear categories caught their allocation in 1986 although the fishery by small (< 65') otter trawlers (OT) was closed or restricted 6 times during the year (Table 2). The small mobile gear sector has misreported 4X cod to 5Y in previous years (documented in Campana and Simon, MS 1985), necessitating adjustment of reported catches. Since misallocation was also apparent in 1986, adjustments have again been made (Table 3). A more serious misreporting problem first became apparent in 1986: comments by both fishermen and port samplers indicate that substantial quantities of cod were either unreported during the year or incorrectly reported as other species such as white hake. It was impossible to quantify the magnitude of this underreporting, but its extent appeared to greatly exceed that of previous years. Therefore, reported catches may underestimate actual catches by anywhere between 10-40%.

A breakdown of nominal catches by gear, tonnage class, and unit area over recent years is presented in Table 4. As indicated in Figure 4, catches peaked in the summer months. Landings were split between otter trawlers and fixed gear, but the former continued their recent domination of the fishery. Catches by TC-1 vessels accounted for 34% of the total in 1986, similar to the proportion reported last year, but considerably lower than that of previous years. Much of this decline was attributed to reduced catches by longliners, who in turn blamed dogfish and aberrant temperature conditions for their reduced effort (Campana and Simon, MS 1986). It now appears that the low mature stock biomass in 4X is an equally plausible explanation.

Stock Abundance Indices

Commercial Catch Rates

Catch rates for 4X cod were calculated for 6 gear/TC categories (4-Longline (LL); 2-otter trawl (OT) selected on the basis of available effort data. Catch rates were calculated on a quarterly basis and then standardized. Standardization was conducted through normalization of the mean post-1976 catch rate within a given gear/quarter; yearly values were then averaged across gears. The results indicated that the strong downward trend noted in the last assessment was continued into 1985 (Table 5; Figure 5). This trend was consistent among gear types, although as an indicator of

the trend in cod abundance, it was confounded by misreporting by the OT sector, the multispecies nature of the fishery and the increased abundance of dogfish in 4X (Annand, MS 1985). Reported longline effort has declined by over 50% since 1982, while that of otter trawlers has increased over the same period (Table 5).

Research Vessel Surveys

Random stratified surveys of the Scotian Shelf have been conducted since 1970; Strata 70-95 comprise the offshore and Bay of Fundy region of 4X (Figure 2). Inshore regions are not surveyed due to the prevalence of rough bottom. Surveys between 1970 and 1981 were carried out by the A.T. Cameron, while the Lady Hammond was used in 1982 and the Alfred Needler in subsequent years. As per the recommendation of the Statistics, Sampling and Surveys Subcommittee of CAFSAC, no inter-vessel conversion factors have been applied. All RV data have been presented in terms of Alfred Needler trawlable units (34' wingspread).

Age-structured survey population estimates are presented in Table 6a. Table 6b presents the same data adjusted to the beginning-of-the-year (through within-cohort geometric means of adjacent years). While age 5+ numbers fluctuated in the early 1970s, the years between 1979-85 suggested relative stability (Table 6). However, all RV indices of stock abundance (Figure 6) and biomass (Figure 7) declined substantially in 1986. No prominent trends in weights-at-age (weighted by stratum area) are evident over the past 6 years (Table 7). With respect to incoming recruitment, the 1984 year-class appears to be particularly weak, while the 1983 and 1985 cohorts are about average.

Age Composition of the Catch

In the last assessment, quarterly age-length keys were computed for each of the major gear types (pooled among tonnage classes) for the period 1948-85. Details of key construction and sample aggregation policy are described elsewhere (Campana and Simon, MS 1986). Fifty samples went into the construction of the 1986 keys. Length-weight relationships were derived from seasonal RV data; in years where a survey was not conducted, seasonal means were applied.

Quarterly landings data and sample information for 1986 are presented in Table 8. Numbers at age (1986) for each of the major gear categories are presented in Table 9. Catch numbers-at-age for the miscellaneous gear category was computed quarterly, through a pro-rated comparison of miscellaneous landings with the sum of OT, LL, and GN landings. Foreign catches were treated similarly, but were pro-rated only on the basis of OT landings (since all foreign catches employed trawl gear). The data for previous years has been presented elsewhere (Campana and Simon, MS 1986).

Total catch numbers and percent catch numbers-at-age are presented in Tables 10 and 11. A comparison of the 1986 catch composition and that predicted last year for 1986 indicates that all ages but age 4 were well

predicted (Figure 8). The partial recruitment of age 4 may have been underestimated in last year's assessment. A declining trend in mean weight-at-age 5 in the catch (Table 12) was noted, but was not evident among the other ages. Fish aged 3-4 made up the largest proportion of the catch numbers (66%) while ages 3-6 made up most of the catch weight (75%) (Table 13). Catch composition curves indicate that age 5 fish were fully recruited to the fishery.

Estimation of Stock Size

Survivor Analysis

Survivor analysis was run on 4X cod using a calibration block of 1972-85 (ages 2-7) and full recruitment to the survey gear at age 5. The results are presented in Table 14. Terminal F on 5+ fish was calculated as 0.38 which is identical to that calculated in last year's assessment. However, the coefficients of variation were considerably higher than those of last year and the estimate of terminal fishing mortality appears to be inconsistent with the 1986 RV survey results. Given the fact that the fully recruited F of 1985 now appears to be much higher than that estimated last year, Survivor may be underestimating terminal F for this stock.

Cohort Analysis

Cohort analyses were run on ages 1-13 in the catch-at-age matrix in Table 10. Natural mortality was set at 0.2 and the age of full recruitment at 5. Fishing mortality on the oldest age group was a weighted mean (weighted on population numbers) of Fs on age 6+ fish. Partial recruitment (defined as $F \div$ weighted mean of fully recruited Fs) in the final year was set at the mean of the years 1981-85; the partial recruitment of age 5+ fish in 1986 was set at 1.0. Cohort runs were conducted for terminal Fs of 0.2-0.8 at 0.05 intervals.

Calibration of the SPA

Calibration of the cohort runs was difficult in view of the relative stability in the RV survey estimates since 1972; this resulted in a narrow range of values through which the regression was calculated. While age-by-age, age 4-6 and age 5+ tuning was attempted, regressions were insignificant at all levels of F_t . However, 1975 values were outliers in all of the relationships (Figure 9) and thus removed from subsequent calibrations. The result was a significant regression at $F_t = 0.55$ (Figure 10). The tuning criterion was the correlation coefficient (Table 15). Assumptions of linearity and a normal distribution of residuals were not totally met (Figure 10), but few alternatives were available.

Commercial catch rates were also used in calibration. The mid-year SPA fishable biomass was calculated as

$$(POP \times e^{-(F+M) \times 0.5}) \times \text{mean weight} \times \text{partial recruitment}$$

for each cohort run. Mean partial recruitment-at-age was used for the intervals 1948-56, 1957-65, and 1966-79 (since no temporal trends were apparent in intra-interval PRs). Partial recruitment was set to 1.0 for all fully-recruited ages. When fishable biomass was tuned against the standardized catch rate, none of the relationships were significant (Table 15). However, where F_t exceeded 0.60 the trend in the two series were similar (Figure 11).

Calibration of the cohort run against RV data produced estimates of F_t in the order of 0.55-0.60. This range is somewhat higher than that estimated by Survivor analysis. However, the time series of fully recruited F_t indicates that a 1986 F_t of 0.55 would be comparable to those of the past 25 years and lower than the mean of the past 7 years (Figure 12). Fishable biomass has been declining since 1980, and is now at one of its lowest levels since 1959 (Table 19; Figure 12). Further, the observed mean weight in the catch lies far below that expected of fishing at F_{max} , let alone $F_{0.1}$ (Figure 13). Finally, if misreporting/nonreporting of cod landings increased in 1986, apparent F_t would be lower than that actually present. For these reasons, an F_t of 0.55 was considered to be a minimum estimate for 1985. The corresponding cohort run is presented in Tables 16-17. Partial recruitment values are indicated in Table 18.

Yield Per Recruit

Yield per recruit was calculated in 3 ways: using 1986 population parameters, using the mean of 1982-86 weights at age, and using the mean of 1948-86 weights-at-age and PR. All produced similar results (Table 20). $F_{0.1}$ was calculated as 0.16-0.17, F_{max} as 0.27-0.29, and $F_{0.1}$ yield per recruit as 1.04-1.10.

Recruitment of 4X cod has varied by a factor of 6 between 1948-85, and by only a factor of 2 since 1965 (Figure 14). Long-term yield of 4X cod was estimated from the geometric mean of age 1 recruitment through this period ($18,752 \times 10^3$). Expected annual yield (long-term) at $F_{0.1}$ is 21,000 t.

Catch Projections

Projections were made with the mean of the 1984-86 weights-at-age, the mean PR between 1981-85 and the 1986 population size from the cohort analysis (Table 21). Since the age 2 cohort estimate in 1986 was the lowest observed, it was adjusted upwards to the size of the smallest year-class in the previous 30 years (1981 year-class at age 2).

The 1987 TAC, which is above that recommended by CAFSAC, corresponds to a fishing mortality of 0.47. If $F_{0.1}$ catches in both 1987 and 1988 were realized, catches are projected to be 8,000 and 10,000 t respectively. Given the TAC catch in 1987 (of 17,500 t), the projected $F_{0.1}$ catch in 1988 is 9,000 t. However, since the 1986 F_t exceeds $F_{0.1}$, the 50% rule was applied,

resulting in a 1988 F of 0.34. The 1988 catch at this level would be 14,000 t. Partially recruited ages would make up 35% of the catch biomass.

The long-term yield at $F_{0.1}$ is 21,000 t for this stock.

Conclusions

Historic assessments of this stock have always reported overexploitation (Halliday, MS 1971, MS 1974; Sinclair, MS 1980; de Lafontaine, MS 1981; Gagné et al., MS 1983; Campana and Simon, MS 1984). This view of the fishery was substantiated in 1985 when the first analytical assessment of the 4X stock complex was presented (Campana and Simon, MS 1985). Extension of the SPA back to 1948 revealed a long history of overexploitation (Campana and Simon, MS 1986). However, our current view of the stock suggests that recent fishing mortalities have been taking their toll. The current estimate of fully-recruited F in 1985 is 0.71 — substantially above that of the long-term mean, and more than twice that of F_{\max} . All indices of abundance show a marked decline in 1986 — catch rates have reached their lowest levels since 1976 and RV numbers are at their lowest level since 1973. Of particular concern is the fact that SPA biomass is at a 27-year low. Given these facts, it is possible that stock biomass is approaching a critical level. This view is exacerbated by the absence of strong recruitment in the upcoming year-classes. Since it appears unlikely that stock biomass will increase in the near future, serious consideration will have to be given to stock preservation measures if abundance indices continue their decline in 1987.

* Catches misreported as being from 5Y have been allocated proportionally among OTB TC 2 and 3 vessels in 4X (see Table 3).

A LHP = handline

B See Figure 1 for location of unit area; U = unspecified.

Table 5. Commercial catch rates for otter trawlers (OT) and longliners (LL) in 4X (all unit areas combined). Effort values in parentheses. a) Effort units are hundreds of lines (LL) and tons/hr (OT); b) Effort is in terms of days fishing.

Table 6. Numbers-at-age ('000) in RV surveys of 4X cod. Surveys between 1970-81 were made by the A.T. Cameron; 1982 by the Lady Hammond; and 1983-86 by the Alfred Needler. All values converted to Needler trawlable units. No other inter-vessel conversion factors were used. a) summer; b) beginning of year numbers calculated from the geometric mean of within-cohort values between adjacent years.
