¹This series documents the scientific basis for fisheries management advice in Atlantic Canada. As such, it addresses the issues of the day in the time frames required and the Research Documents it contains are not intended as definitive statements on the subjects addressed but rather as progress reports on ongoing investigations.

Research Documents are produced in the official language in which they are provided to the Secretariat by the author(s).

¹Cette série documente les bases scientifiques des conseils de gestion des pêches sur la côte atlantique du Canada. Comme telle, elle couvre les problèmes actuels selon les échéanciers voulus et les Documents de recherche qu'elle contient ne doivent pas être considérés comme des énoncés finals sur les sujets traités mais plutôt comme des rapports d'étape sur les études en cours.

Les Documents de recherche sont publiés dans la langue officielle utilisée par les auteur(s) dans le manuscrit envoyé au secrétariat.

ABSTRACT

Following the Inshore / Offshore Agreement of September 1986, major changes apply to the management of the scallop fishery in Bay of Fundy waters with a series of conservation initiatives for the Bay and its approaches (extension of fishing grounds from 7-mile to the middle of the Bay, extension of the 'conservation' zone, and regulations dealing with meat count, minimum shell height, and maximum over-all width of the gear).

There is little inter-annual variation in the scallop landings from southwest New Brunswick, at around 250 t. per year. Scallop beds in the Grand Manan area make up the majority of landings. On an area basis, CPUE from these beds used to represent the most productive areas. In 1987, the mean CPUE from the five most productive areas was 37 % greater than in 1986 (3.40 vs 2.48 kg./ hm) and represented heavy exploitation of grounds in Passamaquoddy Bay and the Deer Island area. Catches in offshore waters (NAFO 5Yb) have decreased by 50 % from last year. Survey results indicate a slight pulse of young scallops (ages 3 - 5) in the nearshore waters of Grand Manan; otherwise these stocks are at a low level.

RESUME

A la suite de l'Entente de septembre 1986 entre la flotte hauturière et les flottilles côtières, des changements majeurs s'appliquent à la gestion de la pêche aux pétoncles dans la Baie de Fundy avec l'introduction de mesures de conservation pour la Baie et ses approches: extension de la zone de pêche de 7 milles au milieu de la Baie, prolongation de la zone de 'conservation', et règlements concernant le compte de chairs, une hauteur de coquille minimale, et un maximum de la largeur hors-tout de l'engin de pêche.

Les débarquements de pétoncles du sud-ouest du Nouveau Brunswick varient peu d'année en année, à environ 250 t. annuellement. Les bancs de pétoncles de l'île de Grand Manan constituent la majorité des débarquements. Sur une base régionale, les P.U.E. de ces bancs avaient représenté les régions les plus productrices. En 1987, la P.U.E. moyenne des cinq régions les plus productrices était 37 % plus élevée que celle de 1986 (3.40 vs 2.48 kg / hm) et correspond à une exploitation intensive des bancs de la Baie de Passamaquoddy et de Deer Island. Les captures des eaux profondes (OPNA 5Yb) ont diminué de 50 % depuis l'année dernière. Les résultats de l'inventaire des stocks indiquent une légère abondance de jeunes pétoncles (3 - 5 ans) dans les eaux côtières de Grand Manan; ailleurs, les stocks sont à un bas niveau.

INTRODUCTION

Following the Inshore / Offshore Agreement of September 1986, major changes apply to the management of the scallop fishery in Bay of Fundy waters with a series of conservation initiatives for the Bay waters and its approaches. Starting with the year 1987, exploitable grounds were extended from 7 miles from the New Brunswick shore to the middle of the Bay of Fundy for the 'inshore' scallop license holders of the southwest shore of New Brunswick. New Brunswick license holders are now referred to as "Mid-Bay" license holders.

The 2-mile 'conservation' zone in Grand Manan waters where fishing is allowed only between the second Tuesday of January and the end of March each year, was also extended to the shoreline of New Brunswick up to the Saint John - Albert county line.

New regulations came into effect in December 1987 with respect to the scallop fishery in Bay of Fundy waters (Canada Gazette Part II, Vol. 121 no.25, SOR / DORS / 87-672). Highlights are the introduction of meat counts, 72 meats per 500 g during the period May 1 to September 30 and 55 meats per 500 g during the period October 1 to April 30 and a minimum shell height of 76 mm. Regulations dealing with scallop fishing gear were modified and expanded; a maximum over-all width of the gear (5.5 m) was re-introduced; offshore rake and 'Green' sweep drag were banned.

There is little inter-annual variation in the scallop landings from southwest New Brunswick after the outstanding record landings of 1981 (over 500 t). The extension of fishing grounds to Mid-Bay license holders did not result in an increase in landings as the productivity of the newly assigned grounds is somewhat marginal.

The aggregations of juvenile scallops first noticed in the 1986 stock survey were observed again in the 1987 survey. This significant increase in numbers of young scallops only took place in localised areas.

METHODS

Fishery Data

All vessels must be licensed for fishing scallops in this area (Mid-Bay or Bay of Fundy scallop license) and must maintain logbooks on a daily basis for vessels over 25.5 G.T. and/or length overall greater than 14 m. Daily log records supply information on the catch and its location, and fishing effort such as hours spent dragging, width of the gear, and number of crew. CPUE estimates may be computed when complete effort data are provided with respect to the catch; these data have been designated as Class 1 data.

The information provided by vessels over 25.5 G.T. form the basis of the fishery analysis presented here. It might not necessarily reflect the fishing performance of vessels under 25.5 G.T. Hence, landings from this sector of the fleet in that geographical area (Statistical Districts 48 to 53) (Fig. 1) are used to represent their contribution to the catches of this area. It is also possible since 1985 to compile landings on a per vessel basis, match these figures to landings per statistical district, and estimate, although roughly, a mean catch per vessel under 25.5 G.T.

Survey Data

Survey work took place in October, 1987 except for a few stations in the Duck Island Sound area which were sampled in December, 1987. 125 sampling locations were randomly selected according to the traditional effort expended from 1983 to 1987 (up to September) in the Grand Manan area according to logged data. It is becoming difficult to stratify the survey locations

according to the commercial catches (with known locations) of the previous year only, fewer catches being logged due in part to the lower stock abundance.

Survey data has been post-stratified two ways. For comparative purposes with surveys of previous years, survey stations have been clustered in two groups: 1) inside 7-mile line; 2) outside 7-mile line. Then, because the outside 7-mile zone covers a bigger geographical area the data were further post-stratified in three areas: 1) southern area (shallow waters to the south of the Island); 2) western area (Grand Manan Channel and Seal Island); 3) northern area (Wolves Bank and vicinity) (Fig. 2).

A four-gang 76.5 cm Digby drag with 76 mm rings linked with rubber washers was used with the two middle buckets lined with 38 mm stretched mesh netting. Survey procedures followed the ones given in Robert et al (1984). Tow track was monitored by the recording of Loran bearings every 30 seconds during a tow.

To interpret the survey catch-rates in terms of stock distribution on an age basis, some scallops were collected throughout the 1986 survey to estimate a growth curve (von Bertalanffy). About 500 shells were ring-read to establish the following growth parameters:

$$H_{\infty} = 134.553 \text{ mm} \qquad k = 0.265 \qquad t_0 = 1.344$$

There is no information available on the composition of the commercial catch for these scallop beds.

RESULTS

Fishery Performance

The number of Bay of Fundy licensed vessels has remained constant for the last 3 years (Table 1). The number of Mid-Bay licenses which had reached a maximum in 1981 (Robert et al 1984) remains at a fairly high level although a sizable drop in renewed licenses took place in 1987. The number of active fishing licenses has not changed though. The majority of the Mid-Bay licenses are vessels which do not have to report their fishing activities because of their size. However since 1985, it is possible to compile catch statistics on a per vessel basis and get a crude estimate of the participation rate of vessels under 25.5 G.T. as recorded by sale slip submissions and of catch per vessel. Out of the total number of Mid-Bay licenses issued to vessels under 25.5 G.T. annually, it appears that an important percentage (50 % ?) are not used as no sales slips in the name of the vessel are submitted. However, the ratio of inactive licenses decreased for 1987. Most vessels over 25.5 G.T. hold a Bay of Fundy license and are actively involved in the fishery although not necessarily in the waters of southwest New Brunswick exclusively. Their involvement has been constant for several years now, except that an increasing number have declined to comply with log procedures. This reduction in log compliance impedes the information data base toward analysis of the fishery performance.

Scallop landings from southwest New Brunswick continue to decline after the 1981 record breaking figure (Table 2 and Figure 3); this downward trend is progressing slowly after an initial sharp drop. The geographical location of statistical districts 48 to 53 and designation of relevant NAFO sub-subareas are illustrated in Figure 1. About 250 t were landed in statistical districts 48 - 53 during 1987. Larger vessels (L.O.A. 13 - 19.8 m) conducted some fishing trips to Georges Bank between May and August and exploited the inshore zone of Digby at the opening of the season in October. It is estimated that approximately 40 t landed in southwest New Brunswick, especially district 50, were not caught in the immediate area.

Tables 3 to 5 give recent landings on a monthly basis by statistical district and by vessel size. "Inshore" vessels using ports on Grand Manan Island (district 50) conduct a winter fishery with a marked seasonal trend in landing patterns. With decreasing fishery performance in 1987

January-March landings are reduced. The continued relatively high landings of the 1987 summer originated from Georges Bank. Logged data did not show important fishing activity during the summer time. In comparison, districts other than 50 contributed relatively little.

Since effort data is not available from 'inshore' vessels, evaluation of the performance of that fishery sector is rather difficult. Since these small size vessels are somewhat limited by weather and sea conditions in the geographical coverage and distances to the areas they may possibly fish it is assumed that they exploit fishing grounds in the immediate vicinity of home ports and a vessel's performance is indicative of the status of the stocks in the area. A major caveat to this statement is that these vessels are engaged in a multi-fishery system. If a particular fishery is, at one point in time, getting outstanding results fishermen may elect not to get involved in the scallop fishery for a certain period of time regardless of the status, good or bad, of the scallop resource in the area. Participation in other fisheries in some loose terms has to be considered in the process of interpretation of the performance of vessels involved in the scallop fishery.

Once a data base has been established including more than a few years' worth of results, analysis of vessel performance may become a worthwhile exercise in the present context. Table 6 presents a short time series of catch-rate for inshore vessels on an annual basis for Mid-Bay license holders registered in southwest New Brunswick. There is a great deal of diversity in the exploited scallop beds in this area; a mean annual catch per vessel per district is also calculated. Grand Manan (Statistical district 50) vessel catch-rate experienced an important reduction in 1987 while in the Saint John district (48) and Campobello (51) mean catch per vessel were up considerably.

Fishery characteristics in terms of effort and catch-rate are derived from Class 1 data originating from logbook analysis. Over 70 % of the logged catches contribute to Class 1 data (Table 7). But, the proportion of logged catches compared to all catches that are required to be logged according to Section 48 of the Fisheries Act has been steadily declining. In 1987, a mere 14 % of scallops landed were also reported in logbooks. Such a data base has to be interpreted with caution. Moreso when offshore landings represent about 25 % of the combined inshore-offshore landings for the area.

Southwest New Brunswick

Southwest New Brunswick by opposition to Grand Manan offshore waters designate the shallow waters to the south and southeast of Grand Manan Island, Wolves Bank, Campobello, Deer Island, and Passamaquoddy Bay (NAFO sub-subarea 4Xs in part). Mean catch-rates had suffered quite a drop from 1985 to 1986 (Table 8); but average values have bounced back in 1987. From 1986 to 1987 effort decreased markedly for similar Class 1 catch data. Catch-rates have further rebounded to 1984, 1985 values. Tables 9 to 12 present fishery characteristics for individual fishing locations for 1984 to 1987. Table 13 is similar but covers Campobello, Deer Island and Passamaquoddy Bay areas. Scallop beds in the immediate vicinity of Grand Manan were usually the most heavily exploited. This year, scallop beds of Deer Island and near Saint Andrews have contributed the best areas to the scallop fishery; but their production is quite irregular. Even though the Class 1 catch and catch-rate to a lesser extent, might vary greatly for a single fishing area depending, in part, on the information received for any one year, there is a general trend of decline in both catches and catch-rates best shown when all fishing grounds are examined in a single group. This trend (Table 8) is slightly reversed in 1987 because of the relatively high exploitation of grounds outside Grand Manan waters per se.

This is best illustrated in Table 14 which presents a 5-yr profile of the five most productive areas. Up to 1987, CPUE was declining while the contribution of the top 5 areas was becoming a greater percentage of the areas fished; areas were shifting rank but the same areas (more or less) remained in the top five. In 1987, CPUE rose significantly and the most productive areas represented 81 % of the total areas fished. Most importantly, these areas except for Duck Island Sound had not been in the ranks before.

Grand Manan Offshore Waters

Grand Manan offshore waters define fishing areas outside the 7-mile line like Southwest Bank but also grounds in NAFO sub-subarea 5Yb such as Grand Manan Channel. This area has been exploited recently by vessels under 25.5 G.T. mostly (Table 15) with a sporadic profile of landings. Catches for 1987 show a 50 % reduction compared to last year. Monthly catches from sub-subarea 5Yb (Tables 16-18) follow the same pattern as catches from grounds in the immediate vicinity of Grand Manan with fishery operations peaking in the early part of the year. The fishery performance of Grand Manan offshore waters in Table 19 shows that catch-rates in this area have further dropped after being stable for the three previous years.

Survey Results

Since 1985 the annual stock surveys give good coverage to both nearshore and offshore Grand Manan waters (Table 20). Starting with the first survey in 1979, the inside zone has shown greater abundance of scallops than the outside zone (except for 1980) (Table 21). Area-wise, the northern area mainly representing a scallop aggregation in the vicinity of the Wolves Islands has had low abundance compared to the southern and western areas. In the western area, there is a shift from pre-recruits to recruits from 1986 to 1987. Heavy settlement of juvenile scallops in specific locations of the western area had been observed during the 1986 survey (ages 2 - 3 inside zone). Significant abundances of ages 3 and 4 scallops were further noticed in the 1987 survey (Table 22). Numbers for fully recruited age-classes are remaining very low both inside and outside the 7-mile line. Survey results do not show any sign of pre-recruits for offshore waters (beyond 7-mile line). It therefore appears that a slight pulse of young scallops (ages 3 - 5) in the waters inside 7-mile is the only positive note in an otherwise depleted stock.

DISCUSSION

Although scallop beds in the immediate vicinity of Grand Manan have sustained landings at about 250 t per year for a number of years now, catch-rates have dropped steadily. This trend continued in 1987; average CPUE for 1987 apparently bounced back because of the introduction in the mean values of high rates reached in newly exploited areas outside of the immediate Grand Manan area. Grand Manan catch-rates per se remained at levels similar to pre-1987 ones. Scallop beds in NAFO sub-subarea 5Yb were rapidly depleted ; recent catches being minimal. A slight improvement to the Grand Manan stocks is taking place with a noticeable pulse of ages 4 - 5 scallops in the 1987 stock survey. Harvesting of these year-classes should be postponed for a few years however to increase the meat yield. At the moment, commercial size year-classes are in low abundance so catches should not rise in any significant way. Over the long term, it is doubtful that Grand Manan and southwest New Brunswick waters may produce over 200 t on average (Fig. 3). Erratic fluctuations in catches could be moderated by controlling the effort and optimising the catch yield. The establishment of the 2-mile 'conservation' zone to the New Brunswick shoreline of the Bay of Fundy (restricting the harvesting of the most productive grounds to a short season) and the introduction of meat counts (initially set at 55 and 72 meats per 500 g depending on the fishing season) are steps in the right direction.

Table 22.- Average scallop catch at age per tow for a 4-gang Digby drag for lined middle buckets and unlined outside buckets. Mean total number of scallops per tow and s.d. for year and gear types respectively.

Year and gear type	Age (years)									Mean	s.d.
	2	3	4	5	6	7	8	9	10+		
1983 inside 7-mile lined gear	1	2	2	5	9	19	12	7	7	89	96
1983 inside 7-mile unlined gear	1	4	3	3	6	11	7	5	4	58	63
1985 inside 7-mile lined gear	15	23	5	5	5	7	8	6	8	98	122
1985 inside 7-mile unlined gear	5	11	6	5	8	13	9	8	9	87	96
1985 outside 7-mile lined gear	9	7	4	7	10	6	3	0	0	57	66
1985 outside 7-mile unlined gear	2	5	7	15	17	11	4	2	0	70	76
1986 inside 7-mile lined gear	54	24	12	4	2	1	2	2	8	138	267
1986 inside 7-mile unlined gear	12	13	14	4	3	2	3	3	10	78	163
1986 outside 7-mile lined gear	6	6	3	3	2	3	2	1	3	37	47
1986 outside 7-mile unlined gear	2	3	2	2	3	4	3	2	7	33	34
1987 inside 7-mile lined gear	17	36	36	19	8	3	2	2	7	144	232
1987 inside 7-mile unlined gear	3	18	38	25	10	4	3	3	11	138	263
1987 outside 7-mile lined gear	2	3	2	2	3	2	1	1	2	30	40
1987 outside 7-mile unlined gear	1	3	3	4	3	2	2	1	4	29	35

Figure 1.- Geographical location of New Brunswick Statistical Districts 48 to 53 and extent of NAFO sub-areas 4Xr, 4Xs, and 5Yb in the Bay of Fundy and its outer reaches.

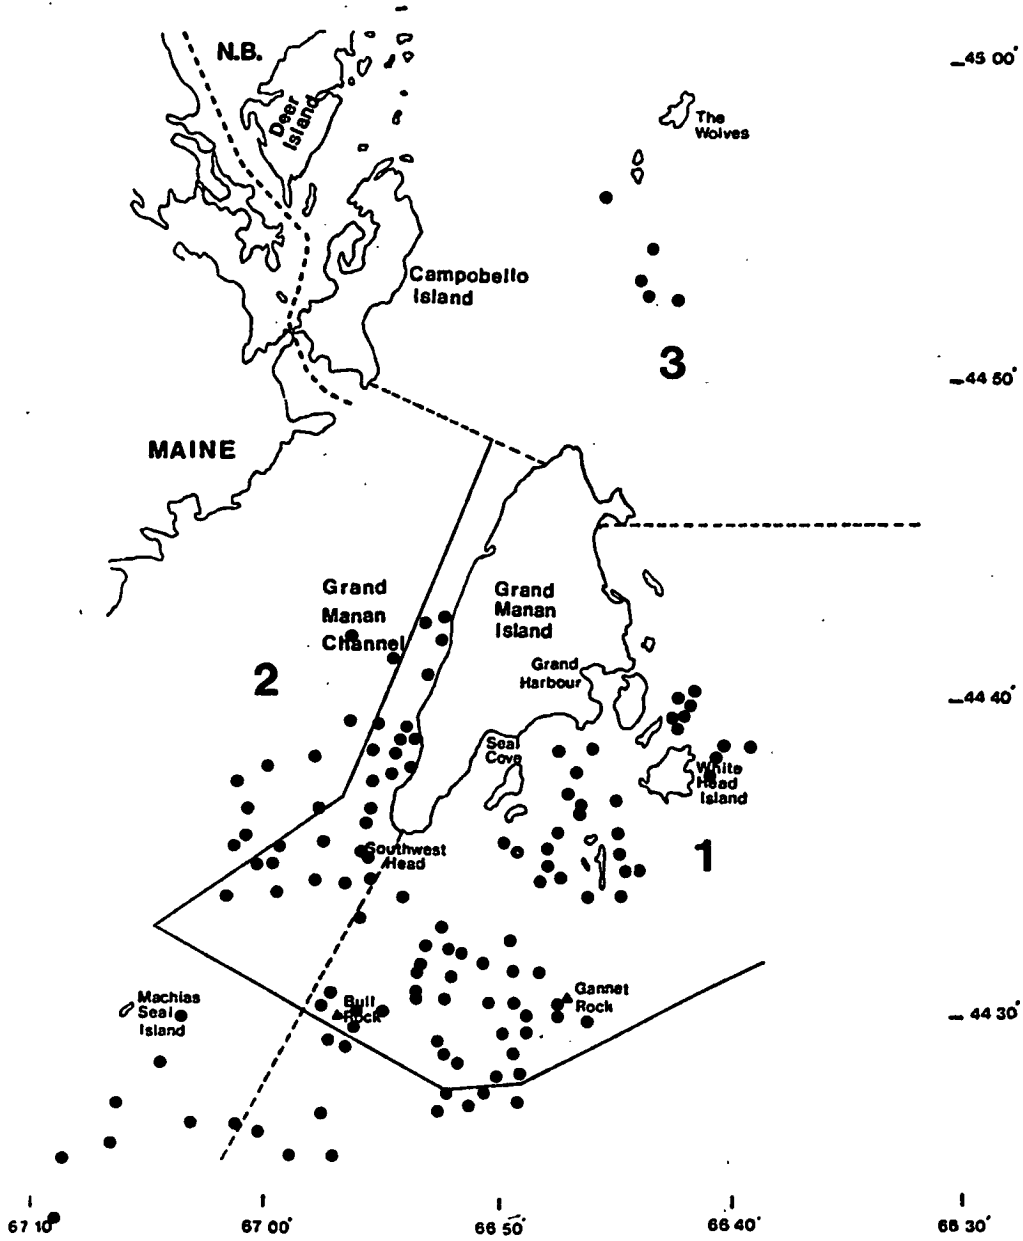

Figure 2.- 1987 survey sampling sites. The continuous line delimits the inside / outside 7-mile zone while the dashed line segregates areas 1) southern, 2) western, and 3) northern.

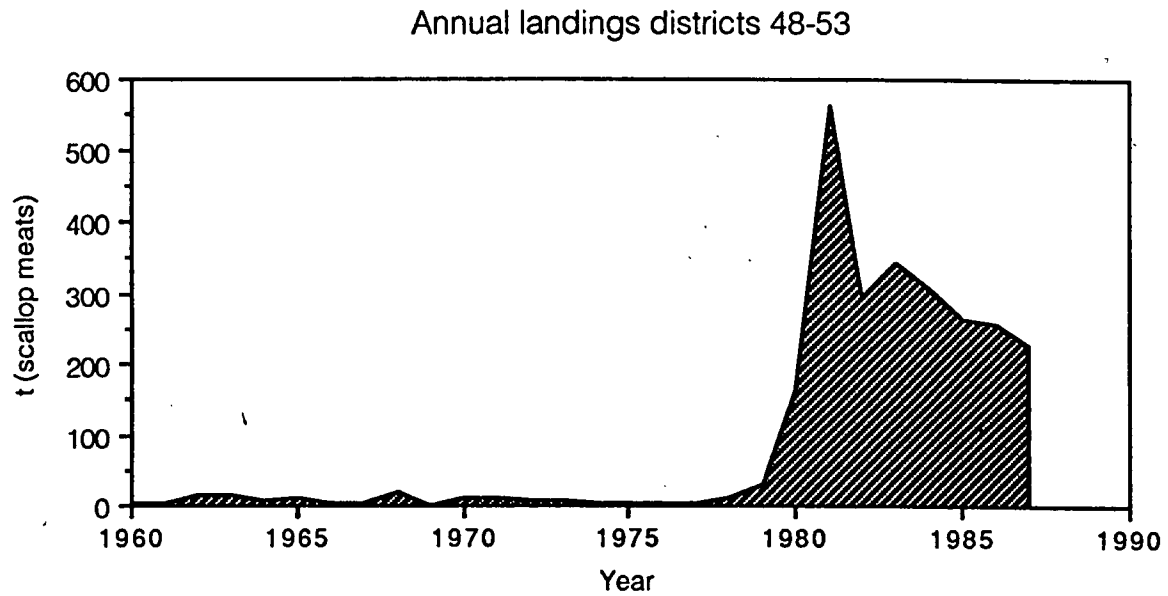

Figure 3.- Profile of the annual landings (t of scallop meats) for the statistical districts of southwest New Brunswick since 1960. Landings were negligible prior to the 1980s at which time, they rose remarkably in 1981 (562 t) to maintain an annual level in the order of 250t afterward.
