#### Abstract

1 This series documents the scientific basis for fisheries management advice in Atlantic Canada. As such, it addresses the issues of the day in the time frames required and the Research Documents it contains are not intended as definitive statements on the subjects addressed but rather as progress reports on ongoing investigations.

Research Documents are produced in the official language in which they are provided to the Secretariat by the author.
${ }^{1}$ Cette série documente les bases scientifiques des conseils de gestion des pêches sur la côte atlantique du Canada. Comme telle, elle couvre les problèmes actuels selon les échéanciers voulus et les Documents de recherche qu'elle contient ne doivent pas être considérés comme des énoncés finals sur les sujets traités mais plutôt comme des rapports d'étape sur les études en cours.

Les Documents de recherche sont publiés dans la langue officielle utilisée par les auteurs dans le manuscrit envoyé au secrétariat.

Abstract
This paper documents recent information relevant to capelin in SA2+Div. 3K. Part A provides information on catch trends and TAC's in both the inshore and offshore areas from 1977-87.

Part B presents data on the offshore fishery and groundfish surveys. The geographical and seasonal pattern of the offshore catch in 1987 is similar to that in 1986 and during 1972-78 although the 1987 catch is much lower. The 1987 catch rate was the highest on record. Commercial catch rates during 1986 and 1987 from observer data were higher than those from NAFO data. The offshore commercial catch was dominated by the 1985 year-class (44\%) followed by the 1983 year-class (32\%) and the 1984 year-class (19\%). The distribution of capelin catches during groundfish surveys compared to the Canadian acoustic survey indicated that the acoustic survey coverage was better in Div. 2J and Div. 3K.

Part C presents information on the concept of parallelism in year-class strengths of capelin by examination of age-composition and biomass estimates. This analysis indicates that the 1973 and 1983 year-classes were strong, the 1979, 1980 and 1982 year-classes were above average and the 1974-78 year-classes were weak in the Div. 3NO, Div. 3L and Div. 2J3K capelin stocks.

Part D contains data on the 1987 inshore fishery in Div. 3K. The 1987 catch was strongly dominated by the strong 1983 year-class, representing $82.5 \%$ of the total catch in numbers. Reported discards for all gear types increased substantially from 1986 levels and were the highest, proportionally to logbook landings since the research programme began operations. Catch rates of purse seines declined from 1986 but for traps, catch rates were highest in the series. However, the 1987 catch rates must be interpreted with caution because the conduct of the fishery was abnormal because of a labour dispute.

Part E describes the 1987 hydroacoustic survey of capelin in NAFO Div. 2J3K. Total capelin biomass was estimated at $134,000 \mathrm{t}$ and two year-old capelin dominated.

## Résumé

Cet article fait état des derniers renseignements recueillis sur le capelan dans 1a SA2 + Div. 3K. La partie A porte sur les tendances pour ce qui est des captures et sur le TPA dans les secteurs côtier et hauturier de 1977 à 1987.

Dans la partie $B$ on présente des données sur la pêche hauturière et les relevés de poissons de fond. Aux points de vue géographique et saisonnier, les prises de pêche hauturière de 1987 sont comparables à celles de 1986 et de 1972 à 1978, bien
que les prises de 1987 soient beaucoup plus faibles. Le taux de capture de 1987 était le plus élevé jamais observé. En 1986 et 1987 , les taux de capture de pêche commerciale étaient plus élevés d'après les données des observateurs que d'après celles de l'OPANO. Dans la prise de pêche hauturière commerciale, la classe de 1985 était prédominante ( $44 \%$ ); venait ensuite la classe de 1983 ( $32 \%$ ), puis celle de 1984 ( $19 \%$ ). En comparant la distribution des prises de capelans dans les relevés de poissons de fond à celle des relevés acoustiques canadiens, on a constaté que le relevé acoustique a été plus complet dans les Div. 2 J et 3 K .

Dans la partie $C$, on traite du parallélisme des effectifs de classe d'âge des capelans en examinant la distribution des âges et la biomasse estimée. L'analyse révèle que $1^{\prime}$ effectif des classes de 1973 et 1983 était élevé, que celui des classes de 1979 , 1980 et 1982 était supérieur à la moyenne et que celui des classes de 1974 à 1978 était faible dans le stock de capelans des Div. 3NO, 3L et 2J3K.

Dans la partie $D$, on présente des données sur la pêche côtière de 1987 dans la Div. 3K. La classe de 1983, dont l'effectif était élevé, était nettement prédominante dans la prise de 1987 , représentant en nombre $82,5 \%$ des prises totales. Les rejets signalés pour $1^{\prime}$ ensemble des techniques de pêche avaient considérablement augmenté par rapport à 1986 et étaient les plus élevés, proportionnellement aux débarquements consignés aux journaux de bord, à être enregistrés depuis l'ouverture du programme de recherche. Les taux de capture à la senne coulissante ont baissé par rapport à 1986 , mais les taux de la pêche au casier étaient les plus élevés de la série. Néanmoins, il faut interpréter ces données avec prudence, car un conflit de travail a perturbé la pêche en 1987.

Dans la partie $E$, on donne les résultats du relevé hydro-acoustique des capelans effectué en 1987 par 1'OPANO dans la Div. 2J3K. La biomasse totale de capelans est estimée à 134000 t ; les capelans de deux ans prédominent.

## Introduction

This document provides information pertinent to the capelin stock occurring in NAFO SA2 + Div. 3K. Catch information is found in Part A. Part $B^{*}$ includes catch rates and age compositions from the offshore fishery, a comparison of the areal coverage of the commercial fishery and the Canadian acoustic survey and distribution of capelin catches from the Canadian groundfish research surveys. Part $\mathrm{C} *$ provides historical documentation and discussion of parallelism in year-class strength of capelin in three stocks (Div. 2J3K, Div. 3L, and 3NO). Part D* summarizes the events of the 1987 inshore fishery, presents age-composition data derived from commercial samples and analyzes research logbook data submitted by commercial fishermen. Part E* presents the results of an acoustic survey conducted by Canada during the fall of 1987 .

## A. Catch trends

The capelin fishery in NAFO SA2 + Div. 3K was, until 1972, a small inshore domestic fishery occurring during the spawning season. In 1972, substantial offshore catches were reported. These catches peaked in 1976 at $212,000 \mathrm{t}$ and declined during the late 1970 's to $11,000 \mathrm{t}$ in 1979. These offshore catches were taken mostly by USSR midwater trawlers. During 1980-82, the only directed offshore catches were taken in an experimental USSR midwater trawl fishery.

Since 1983, all offshore catches have been taken by USSR midwater trawlers. In most years, the offshore fishery occurred during August-December with peak catches occurring in September-November (Fig. 1). During 1972-82 and 1985, catches occurred in Div. 2J only while in other years catches occurred in both Div. 2J and Div. 3K.

In recent years, a small directed inshore fishery for roe has been conducted during June and July. In 1987, inshore capelin landings in NAFO SA2 + Div. 3K were the second highest in the series (Table 1) with all the fishing effort occurring in a single week in June.

The inshore capelin fishery has been regulated by quota management since 1982 (Table 2). White Bay and Notre Dame Bay are the principal bays in Div. 3 K where the fishery operates.

In 1987, the 'normal' pattern of fishing activity was disrupted by a labour dispute. The fishery opened officially on June 1 in all areas of the Newfoundland Region, however, fishing did not begin until June 19 when a settlement was reached. Also on June 19 the capelin quota for SA2 + Div. 3K was revised downward from $15,500 \mathrm{t}$ to 8600 t due to more recent information on a lower than expected market demand for frozen females in Japan. The fishery
*Part B-J. Carscadden, D. B. Atkinson, Part C-J. Carscadden, Part C-B. Nakashima, R. Harnum, Part E - D. S. Miller
was closed to all gear types 6 days later on June 25 in Notre Dame Bay and 7 days later in White Bay and Labrador on June 26.

## B. Offshore fishery and Groundfish surveys

Offshore Fishery:
Catches in 1987 were taken in both Div. 2J and Div. 3K with the Div. 2J catches occurring earlier in the season. This pattern is similar to that of 1986 and reminiscent of the pattern of the fishery during 1972-78 although current catches are generally much lower.

The distribution of samples collected by the Foreign Cooperative Research Section, St. John's in relation to the 1987 Canadian acoustic survey is shown in Figure 2. As in 1986 (Carscadden et al. 1987), there is a general southward seasonal movement of the commercial fleet. During the survey conducted in October 1987, an extra block was added to the east of the "normal" survey area. It would appear that a significant portion of the fishery occurred in the same area covered by this additional block.

## Catch Rates:

Commercial catch rates have been calculated from a number of different sources. One series (USSR/FCR in Table 6) consists of estimates from Seliverstov and Serebrov (1979) for the years 1971-78 inclusive and for 1979-87 estimates are from the Canadian Observer Program (Foreign Cooperative Research Section, D. Kulka, pers. comm.). The estimates for 1972-78 are from BMRT-A Class trawlers whereas the estimates for 1979-84 are from USSR Tonnage Class 7 trawlers but it is not known whether these trawlers are BMRT-A Class.

Data for the USSR OTM 7 fleet collected by the Canadian Observer Program for the years 1979-87 were analyzed using a multiplicative model (Gavaris 1980). All records with catches or effort less than 10 units were removed prior to analysis since it has been shown that rounding errors associated with these small values can introduce bias. An initial unweighted regression was
carried out, and the residuals examined (Fig. 3a, 3b). Based on these it was decided to include all of the data points. Boxplots of the residuals (expressed as percentiles) were done (Fig. 4). These indicated no trends with time but the catch rate in 1980 was much higher than predicted by the model. Further examination of these data (Fig. 5) indicated that catch rates in September were the cause for this so these data were deleted. The regression results after making the above modification (Tables 3a, 3b) indicate that the regression is very highly significant. An examination of the residuals (Fig. 6a, 6b) did not reveal any obvious outliers. A plot of the residuals versus the effort values (Fig. 7) indicates that some heteroscedasticity exists in the data so the regression was re-run weighted step-wise by effort (3 steps: 11-75, 76-225, and 226-362 units). The results (Table 4a, 4b) again indicate a high degree of significance. Boxplots of the residuals (Fig. 8) do not reveal any trends with time. Predicted catch rates, catch and effort are given in Table 5.

Figure 9 shows the differences in catch rates from 1979 through 1987 determined from different data sources and applying different techniques. Generally, the FCR data suggest a gradual increase over the time period for which data are available while the NAFO data show an increase only between 1985 and 1986. The two treatments of the FCR data show differences, since about 1980 in scaling only but the trends are the same. This would suggest that a straight average catch rate derived from these data is adequate and standardization using a multiplicative model is not necessary.

Last year, Carscadden et al. (1987) noted that during 1985 there was a large difference between catch rates derived from the Canadian Observer Program and NAFO Statistics. This also occurred for the 1986 data (Table 6). These large differences in catch rates in these two years are unexpected since the fleet has been well covered by the observer Program and therefore the data collected should be in agreement with the data eventually reported to NAFO by the Soviets.

Age Compositions:
The offshore commercial catch was dominated by the 1985 year-class (44\%) followed by the 1983 year-class (32\%) and the 1984 year-class (19\%) (Fig. 10). The contribution by 4-year-olds is the strongest since 1978 (42\%). The greatest contribution by 4-year-olds occurred in 1977 when the strong 1973 year-class accounted for $60 \%$ of the catch.

During 1972-77, age compositions in the fall offshore commercial fishery agreed reasonably well with the age compositions of the spawning population inshore the following year indicating that the commercial fishery was taking predominantly maturing fish (Carscadden et al. 1985). An examination of data from 1981-87 shows while the agreement is not perfect, the trend is continuing into the 1980's (Table 7).

Canadian Groundfish Surveys:
Stratified-random groundfish surveys in Div. 2J3K have been conducted by GADUS ATLANTICA in most years immediately after the capelin acoustic survey. Tables 8 and 9 are updated from those presented previously (Carscadden and Atkinson 1986; Carscadden et al. 1987). The acoustic coverage of strata in
which capelin were caught during the groundfish survey was generally good in Div. 2 J but not so complete in Div. 3K. It is probable that the catch rates from groundfish surveys are more useful as indicators of distribution of capelin rather than as indices of abundance.

## C. Parallelism in Year-class Strengths of Capelin

The concept of parallelism in the three major stocks of capelin in the Newfoundland area (Div. 2J3K, Div. 3L, and Div. 3NO) has been cited in the scientific literature (see eg. Leggett et al. 1984) but there have been no analyses conducted to support the statement. It should be understood that this concept does not necessarily imply a direct linear relationship between year-class strengths in adjacent stocks but simply that very strong and/or very weak year-classes will often occur simultaneously.

Since the large offshore fishery developed in the early 1970's, a number of year-classes have been cited as being strong, namely the 1969, 1973, 1979, 1980 and 1983 year-classes while year-classes 1974-78 inclusive have been weak. In this section, we examine two types of data to determine if these observations are supported. The two types of data examined are: 1) age compositions and absolute abundances of year-class strength and 2) trends in biomass. In this case, we assume that since a capelin population contains only 4-6 age-classes (ages 1-7) or in a mature population only 2 age-classes (ages 3 and 4) predominate the presence of an exceptionally strong year-class will result in a large increase in biomass. Thus, a large increase (or decrease) in biomass in all stocks would indicate the presence of a strong (or weak) year-class in all stocks.

Age Compositions:

The data in Table 10 are from Carscadden (1978) and give age compositions of capelin from Div. 3N, 3L and 3P during the late 1960's and early 1970's. During this time period, the 1969 and 1973 year-classes were considered to be strong. In Div. 3N, the 1969 year-class does not show up strong as 3-year-olds but does appear strong as 4-year-olds. The 1973 year-class makes up a significant proportion of the population as 3-year-olds.

In Div. 3P, 3-year-olds dominated every year.
In Div. 3L, 4-year-olds dominated except in 1976, when 3-year-olds (1973 year-class) were dominant.

Age composition data for the $1980^{\prime}$ s for Div. 3N acoustic surveys and from Div. 3L and 3K inshore fisheries are shown in Table 11. During this time period, the 1983 year-class was considered very abundant with the 1979 and/or the 1980 year-class considered to be above average. In Div. 3N both the 1979 and 1983 year-classes appeared relatively large (Table 11). This is also true for the abundance data (Table 12).

In Div. 3L, both the 1979 and 1980 year-classes appeared relatively strong (Table 11). The 1983 year-class appeared relatively abundant as 3-year-olds but the relative strength of this year-class in this area cannot be fully assessed until the 1987 age-composition data are available.

In Div. 3 K , the 1979 , 1980 and 1983 year-classes appeared strong (Table 11). The 1983 year-class appeared very strong as 4-year-olds although this value may be biased up due to an anomalous fishery in 1987. The 1980 year-class appeared relatively strong even as 5-year-olds.

Age-composition data are available for the offshore fishery in Div. 2J3K since 1972 (Table 13). Both the 1969 and 1973 year-classes appeared in the fishery in some strength over a number of years, the former as 3-, 4-, and 5-year-olds and the latter as 2-, 3-, 4-, and 5-year-olds. During the late 1970's other year-classes appear relatively strong but probably weren't because at that time the biomass was very low (see below). The 1979 and 1980 year-classes may be average or above average. The 1983 year-class is strong; it has appeared in the fishery in some strength at ages 2-5 and most indicators show the stock biomass is increasing.

Relative strengths of year-classes from acoustic surveys and inshore catch rate data from Div. 3L during the late 1970's and 1980's are shown in Figure 11 and 13 (Carscadden et al. 1987). From standardized density and abundances at age 2 from offshore spring and summer acoustic surveys, the 1983 year-class appeared very strong (Fig. 11). From trap catch rate data (Fig. 12), the 1978 and 1981 year-classes appeared weak while the 1979 and 1982 year-classes appeared relatively strong. The 1983 year-class was fairly strong as 3-year-olds; confirmation on whether the 1983 year-class is strong will await the analysis of 1987 data. A similar pattern was apparent from purse seine catch rates (Fig. 13) with the 1978 and 1981 year-classes relatively weak compared to other year-classes.

During the late 1970's and early $1980^{\prime}$ s, sequential capelin abundance models were used to assess the Div. 3 L and 2 J 3 K capelin stocks. The relationship between 2-year-olds from both stocks as derived from these models is shown in Figure 14 (Carscadden and Miller 1979). The 1973 year-class was very strong and makes a significant contribution to the regression but the relationship would probably still be significant with only the other points included.

With the exception of only a few years, the Soviets have been conducting fall acoustic surveys in Div. 2J3K since 1974 and the numbers-at-age and standardized numbers-at-age from these surveys are given in Tables 14 and 15, respectively. The 1983 year-class was strongest at age 2 and 3 followed by the 1973 class. The 1979,1980 and 1982 year-classes were also strong or at least above average.

## Biomass Estimates:

All biomass estimates for the Div. 3NO capelin stock have been produced by USSR and Canada with the exception of one estimate in 1972 by Norway (Fig. 15). USSR surveys do not cover the same area at the same time of year and in recent years it is not possible to separate the biomass estimates in Div. 3L and Div. 3NO. Canadian estimates are available only since 1981.

Biomass was high in the mid-1970's, declined during the late $1970^{\prime} \mathrm{s}$, and early $1980^{\prime} \mathrm{s}$, and has increased since, although biomass levels in the $1980^{\prime} \mathrm{s}$ are not as high as in the mid-1970's. The trends in biomass are consistent
with the presence of a strong 1973 year-class, then a series of weak year-classes in the late 1970's and fairly good year-classes during the 1980's.

There is not a good time series of biomass estimates for Div. 3L (Fig. 16). However, from the limited data, it would appear that biomass was low in the late $1970^{\prime}$ s and early $1980^{\prime}$ s and then increased dramatically in the mid-1980's, consistent with the presence of a strong 1983 year-class.

Biomass estimates for the Div. 2J3K stock from USSR acoustic surveys from 1972-86 show a trend of high biomass in the 1970 's, low biomass in the late 1970's and early 1980's, and an increase in the mid-1980's (Fig. 17). This trend is consistent with the presence of a strong 1973 year-class, poor year-classes between 1974 and 1978, a strong 1979 and 1980 year-class and a much stronger 1983 year-class.

Estimates from a sequential capelin abundance model are available from 1972 to 1980 and show the same trend as the acoustic estimates (Fig. 17). The 1973 year-class was the strongest in the series.

Biomass estimates from Canadian acoustic surveys are available only from 1983 to 1987 and show a peak in 1985 (Fig. 17).

Catch rate data from the offshore fishery (Table 6) show a pattern similar to the USSR acoustic surveys with high biomas in the mid-1970's, a decline in the late $1970^{\prime} \mathrm{s}$, and an increase in the $1980^{\prime} \mathrm{s}$.

Summary:
While the data are occasionally fragmentary, the age composition and biomass trends considered together would indicate that parallelism in year-class strengths of capelin between the three major stocks (Div. 3N0, Div. 3L, and Div. 2J3K) occurs. The strong 1973 and 1983 year-classes, above average year-classes in 1979, 1980, and 1982 and weak 1974-78 year-classes resulted in high biomasses during the mid-1970's and mid-1980's and low biomasses in the late $1970^{\prime}$ s and early 1980's. These trends occurred in the three stocks considered here.

## D. The 1987 Inshore Fishery in Div. 3K

## Sampling Program:

Commercial samples were collected by fishermen and at fish plants at the rate of two samples per gear type per week per statistical section (Fig. 18) in Div. 3K (Table 16). Only 39 samples were collected and analyzed from the commercial catch because landings were down from 1986 (Table 1) and the fishery was closed 7 days after fishing had begun.

Age Composition of the Catch:
The 1987 catch was dominated strongly by the strong 1983 year-class as 4 -year-olds representing $82.5 \%$ of the total catch in numbers (Table 17). Three-year-olds from the 1984 year-class constituted $10.8 \%$ which was the smallest proportion since 1982 . The 1982 year-class as 5 -year-olds was $6.3 \%$ of the catch.

The catch in 1987 was predominantly older and larger fish because the 1983 year-class made up such a high percentage. However, there was a potential bias in relating the age composition of the catch to the age composition of the mature population. In 1987, the entire fishery was conducted in 8 days and in all likelihood the fishery in Div. 3K operated during the part of the spawning season when the older, larger fish were more likely to be caught. In previous years the fishery was longer, extending into July when smaller, younger fish would have been caught. Consequently, the relative difference among ages in the inshore commerical catch in 1987 should be interpreted with caution. Even if the fishery had been longer, the 1983 year-class would have dominated the catch in 1987 because the 1983 year-class was observed to be strong and the 1984 year-class to be weak in surveys in 1986 (Carscadden et al. 1987).

The age composition of the 1986 catch reported in Carscadden et al. (1987) was updated in this report (Table 17) with more recent landing data for 1986.

## Research Logbook Survey:

In 1987, research logbooks were distributed to 14 purse seine, 11 beach seine, and 16 trap fishermen who live in Div. 3K. Of these six purse seine, five beach seine, and 13 trap logbooks were returned in 1987. All six purse seiners fished exclusively in Div. 3 K . Two trap fishermen each fished two capelin traps in 1987. Six fishermen did not fish capelin in 1987 and 11 logbooks were not submitted.

In 1987, $78 \%$ of the discards by purse seiners was due to the redfeed content (Table 18). In the miscellaneous category, capelin were let go because the amount caught was in excess of vessel capacity. Similarly for beach seiners, $80 \%$ of their discards was related to redfeed problems and the remaining $20 \%$ was attributed to males sorted from their catches (Table 19). For capelin traps there was a wider variety of reasons for discarding part of the catch (Table 19). The main reason which represented $37 \%$ of all trap discards was due to market-related problems such as boat quotas, blocked plants, and the quota being taken. Redfeed content was involved in $27 \%$ of the discards and low percentage of females made up $11 \%$. Similar to purse seiners, the miscellaneous reason for traps was predominantly in excess of vessel capacity. For all gear types no discarding was reported to be due to over ripe, spawned out, or small females. This supports the notion of the short fishery which failed to prosecute the latter part of the spawning period when smaller, younger females would have been available. Thus, redfeed content for all three gear types and market-related problems for traps were the chief reasons reported for discarding capelin in 1987.

Reported discards for all gear types increased substantially from 1986 levels and were the highest, proportionally to logbook landings since the research logbook programme began operations. In our analysis of logbook records, discards constituted $87 \%$ of purse seine landings (Table 20 ), $120 \%$ of beach seine landings (Table 21), and $106 \%$ of trap landings (Table 22). In the majority of reports, capelin were reported released alive at sea. Discarding referred to capelin which were caught and not landed by the individual who
caught them. No distinction was made between fish released alive or let down dead.

Catch/effort data were available from 1981 to 1987 for purse seines and from 1.983 to 1987 for beach seines and traps. Catch/effort (CPUE) estimates of purse seines decreased from 1986 to 1987 (Table 20) with CPUE estimates derived from logbook landings (L) following a steeper decline than those based on logbook catches (C) which included discards. Landings/set in 1987 were the lowest in the series and catch/set was the second lowest. For beach seines, CPUE indices gave mixed signals (Table 21). The 1987 indices based on landings only were the lowest in the series, whereas the catch/day in 1987 was the highest estimate since 1983 and the catch/set was average. For capelin traps, all four CPUE indices were the highest in their respective series (Table 22).

The 1987 CPUE estimates must be interpreted with caution when compared to CPUE values in earlier years because of the short length of the 1987 inshore fishery. The total fishing effort per gear type was considerably lower in 1987 than in previous years (Table 20, 21, and 22). Beach seine landings and fishing effort continued to decline in 1987 as industry relied more on capelin obtained from traps and purse seines (Table 1). Purse seine catches reported in 1987 had high redfeed levels which are indicative purse seine sets early in the spawning period when mature females are still feeding. As spawning progresses, the redfeed levels usually decline and later catches include spent and over-ripe females. In 1987, purse seine activity was curtailed earlier than in other years which may present difficulties in interpreting year to year trends. In 1987, purse seiners fished 5.2 days per vessel compared to 8-10 days in 1981-86. Capelin traps recorded high catches from the opening until the closing date of the fishery which was reflected in their catch/day rate of 10.5 t per day, almost double the 1986 estimate of 5.8 t . In other years traps were out fishing prior to the spawning peak when catches were low and infrequent and remained fishing beyond the spawning peak when spent females were present. Accordingly, the CPUE for traps may reflect higher catch rates than would have been experienced had the fishery not been interrupted by the labour dispute. At this point it is difficult to recast the CPUE's to reflect past fishing patterns. We did observe that all trap indices were the highest in its series, and fishermen reported that capelin were abundant where they were fishing during and after the fishery was closed. Thus the catch rates sustained by the trap fishery in 1987 were probably indicative of high capelin abundance during the fishery, however, the magnitude of the increase from 1986 to 1987 observed in Table 22 may be exaggerated.

## E. Hydroacoustic Survey of Capelin in NAFO Div. 2J3K

A hydroacoustic survey for capelin was carried out in NAFO Div. 2J3K during the period October $10-25$, 1987. This cruise is part of a series of annual acoustic surveys conducted on the Div. 2J3K capelin stock since 1981 (Carscadden et al. 1987, Miller and Carscadden 1984, 1985, 1986).

The configuration of the data acquisition system was the same as used for previous capelin surveys of this stock (Miller and Carscadden 1984) with the following exceptions: 1) the pulse length used was 1.2 milliseconds; 2) the attenuation coefficient ( $\alpha$ ) used was $0.0122 \mathrm{~dB} / \mathrm{meter}$; and 3 ) a new model of
transducer was used, i.e. Ametek-Straza SP303LT. Survey coverage was expanded in 1987 to include an area (Fig. 19, Block E) to the east of the area surveyed in previous years. Fishing sets were conducted using the same strategy as in earlier surveys to obtain samples for determining the age and length composition of the capelin stock.

Figure 19 shows the survey track and fishing set locations during the survey. Figure 20 shows the length and age distribution for each survey block and mean distribution for the entire survey area.

Table 23 is a summary of the results of the acoustic survey. Total capelin biomass is estimated at 133,639 tons. Table 24 presents numbers and biomass at age for all Div. 2J3K acoustic surveys since 1981.
