Witch Flounder in Divisions 2J, 3K, and 3L

by

W. R. Bowering and W. B. Brodie  
Science Branch  
Department of Fisheries and Oceans  
P. O. Box 5667  
St. John's, Newfoundland A1C 5X1

<sup>1</sup> This series documents the scientific basis for fisheries management advice in Atlantic Canada. As such, it addresses the issues of the day in the time frames required and the Research Documents it contains are not intended as definitive statements on the subjects addressed but rather as progress reports on ongoing investigations.

Research Documents are produced in the official language in which they are provided to the Secretariat by the author.

<sup>1</sup> Cette série documente les bases scientifiques des conseils de gestion des pêches sur la côte atlantique du Canada. Comme telle, elle couvre les problèmes actuels selon les échéanciers voulus et les Documents de recherche qu'elle contient ne doivent pas être considérés comme des énoncés finals sur les sujets traités mais plutôt comme des rapports d'étape sur les études en cours.

Les Documents de recherche sont publiés dans la langue officielle utilisée par les auteurs dans le manuscrit envoyé au secrétariat.

### Abstract

Witch flounder has been exploited in this area since the early 1960s mainly by Canada; Poland; the Soviet Union; and, to a lesser extent, by FRG and GDR. More recently, catches have increased in the NAFO Regulatory Area of NAFO Division 3L by Portugal. Catches peaked at 24,000 t in 1973 then declined to an average of about 3,500 t annually since 1979. From 1981 to 1983, estimates of biomass for the stock area averaged 41,000 t; however, overall biomass has declined steadily since 1983 to a level of 20,000 t in 1988, which is now about half the earlier period. While it is difficult to evaluate precisely, at present, it appears that witch may have re-distributed to much deeper waters in recent years. The age span declined considerably since 1976, from a maximum age of 26 years old to 13 years old in 1981, and has remained relatively stable to 1988.

### Résumé

Divers pays pêchent la plie grise dans le secteur considéré depuis le début des années 1960, essentiellement le Canada, la Pologne, l'Union soviétique et, dans une moindre mesure, la République fédérale d'Allemagne et la République démocratique allemande. Récemment, les prises du Portugal dans le secteur réglementé de la Division 3L de l'OPANO ont augmenté. Les prises ont culminé à 24 000 t en 1973 puis, depuis 1979, sont tombées à une moyenne annuelle d'environ 3 500 t. De 1981 à 1983, les estimations de biomasse du stock considéré se sont chiffrées en moyenne à 41 000 t. Toutefois, la biomasse globale a constamment diminué depuis 1983, pour s'établir à 20 000 t en 1988, soit environ la moitié de ce qu'elle était auparavant. Bien qu'il soit difficile de le déterminer avec précision pour le moment, il semble que la plie grise se soit déplacée vers des eaux beaucoup plus profondes au cours des dernières années. La fourchette d'âges a considérablement diminué, puisque l'âge maximal, qui était de 26 ans en 1976, n'était plus que de 13 ans en 1981 et est demeuré ensuite relativement stable jusqu'en 1988.

### Nominal Catches

The commercial fishery began for witch in this area in the early 1960s and increased systematically from 945 t in 1963 to reach a peak at 24,361 t in 1973 (Table 1). In the late 1960s and early 1970s, the major countries prosecuting this fishery were Canada, Poland, and the Soviet Union and, to a lesser extent, the GDR and FRG (Table 1, Fig. 1). Catches declined since 1973 to much lower levels and have averaged about 3500 t annually since 1979 and are now taken mainly by Canada and Poland. In the earlier period, as the fishery developed, significant proportions of the catches came from Div. 2J (Table 2, Fig. 2) - particularly, during the late 1960s and, more sporadically, during the 1970s. In Div. 3L, the contributions to annual catches have been more consistent within the range of 10-20%. Division 3K, by far, comprises the most important proportion of overall catches and, during the early 1980s, accounted for more than 80% of the catch. The catch compositions during the more recent period, however, have been confounded by countries reporting large catches of witch in the NAFO Regulatory Area of Div. 3L (eg., Portugal 1986) (Table 2). Such catches are believed to be highly unlikely.

The fishery, over its history, has been comprised of a domestic inshore gillnet component and an offshore otter trawl component by both domestic and foreign trawlers (Table 3). There has never been an inshore fishery in Div. 2J; however, in Div. 3K and 3L, there have been large inshore components in the 1970s (Table 3) making up a third of the total catch. While proportionately the inshore catch is now much lower, it is still a significant force in this fishery. Provisional catches for 1988 (Table 4) show the catches by stock area for countries other than Can (N) and by division for Can (N). It should be noted that for the EEC, which now includes Spain and Portugal, the levels of catch are highly uncertain from 1986 onward.

In 1988, and again in 1989 (according to boat reports), there has been a highly productive fishery in the Canadian offshore fishery in Div. 3K - in depths of 700-1000 m, at the continental slope. Catches per day have been as high as 30-50 t. This fishery is conducted on a spawning concentration during winter and early spring months, and catch rates drop off quickly by the end of April and early May when the concentration breaks up. It is, therefore, quite probable that catch rates experienced at this time are not necessarily indicative of overall stock size.

### Biological Surveys

Stratified-random surveys have been conducted in the fall in Div. 2J, 3K, and 3L since 1977, 1978, and 1981 respectively. For years when surveys were incomplete, biomass and abundance estimates for missing strata were obtained by applying multiplicative regression analyses. Certain strata that were rarely or never fished and had a high likelihood of zero catches were not included in the analysis. In general, the results suggested very little difference between the actual estimates for the area surveyed and those corrected for missing strata by the multiplicative regression analyses.

#### - Biomass Estimates

For Div. 2J, biomass estimates ranged from 843 t in 1978 to 4142 t in 1986 (Table 5). From 1986, estimates declined - to 1061 t in 1988, the second lowest level in the time series. From Table 5, it can be readily seen that the highest catches are consistently in stratum 212 followed by 211 and 235. These strata are those that comprise the Hawke Channel area to the south of Hamilton Inlet

Bank (Fig. 3). In the early 1960s, during April, there were some notable catches by the research vessel A. T. CAMERON taken in this area - up to 3500 kg per 30-minute set. However, recent attempts by commercial trawlers, in the same month and area, did not catch any commercial amounts of witch.

In Div. 3K, during 1979-85, there appeared to be a period of relative stability where most annual biomass estimates were over 30,000 t (Table 6). The average for the period was, in fact, about 31,000 t. Estimates declined, since 1984 - to a level of 11,965 t in 1988, the lowest in the time series. For the last 3 years, however, estimates have been relatively stable at an average of about 14,000 t. Witch are spread out over a much wider area in this division with most fish being found due east of the 300 m contour - i.e., from strata 625 and 626 eastward (Fig. 4). It is also noteworthy that the average catches in strata 640 and 641 are much higher in recent years. This area is adjacent to stratum 642 where the recent very high catch rates of the commercial trawlers have been experienced during the winter/spring period. It is also important to realize that the period when the decline in biomass began (1984-85) was at the beginning of a very cold period which has been well documented for other groundfish species. It is not inconceivable, then, that survivors would tend to move into deeper, warmer water where they are not as adversely affected. This is particularly the case for witch, which is a relatively warm water fish.

In Div. 3L, biomass estimates of witch for the period 1981-88 have ranged between 4848 t in 1985 and 8078 t in 1982 (Table 7). Except for 1985, the biomass in Div. 3L has been relatively stable, averaging about 7800 t. Given the estimated declines in biomass for Div. 3K, Div. 3L now comprises nearly half of that in Div. 3K. The strata of highest abundance in Div. 3L are 345 and 346 (Fig. 5) which are natural extensions of strata 628 and 638 of Div. 3K (Fig. 4). Other strata of particular significance are 369, 386, and 387 along the northeastern edge and the Nose of the Grand Bank, largely inside the 200-mile limit.

Estimates of biomass for Divisions 2J, 3K, and 3L combined are shown in Table 8 and separately by division in Figure 6. From 1981 to 1983, biomass estimates averaged about 41,000 t; however, overall biomass has declined steadily since 1983 to a level of 20,357 t in 1988, which is now about half of the earlier period.

#### - Estimates of abundance at age

Estimates of abundance at age from the fall surveys are shown in Tables 9-11 for Div. 2J, 3K, and 3L respectively. For Div. 2J, catches ranged from age 4 to age 16 in 1977; however, in 1988, catches ranged from age 5 to age 12 (Table 9). Abundance indices varied but were at low levels over the time period. In Div. 3K (Table 10), the catches were comprised of many more age groups in earlier years with the oldest age in 1988 being 13 years compared to 16 years in 1978. Average abundance during the 1978-82 period was 35 million, 39 million during 1984-85, and 37 million over the 1978-85 period. In recent years (1986-88), the abundance averaged 17 million annually, less than half the previous period.

The abundance indices for Div. 3L (Table 11) were similar to those of the biomass in that they showed relative stability over the period 1981-88. The age

composition was also similar to that of Div. 3K although the abundance was much lower.

#### Commercial catch at age

The commercial catch at age is presented for illustrative purposes (Table 12). While the age range and percent age composition probably represents the offshore fisheries reasonably well, there are some major concerns as to actual removals. For example, the large catches reported by EEC for Div. 3L are highly questionable. Catches by inshore gears - although small, in comparison to the offshore - are probably under-represented in the catch matrix because, logistically, there is difficulty in procuring samples. The age composition, nevertheless, is similar to the survey age composition.

#### Prognosis

In the last review of this stock, CAFSAC observed that this population (more particularly in Div. 3K) appeared to have reached a new equilibrium compared to that of the mid-1970s. The maximum age appeared to be relatively stable at about 14 years old compared to 26 years old as recently as 1976. This situation appears not to have changed over the last few years; however, the estimated biomass for Div. 3K, in particular, has declined to a level which has remained stable since 1986, albeit at a level which is much lower than years prior to 1986. It is difficult, at this time, to determine the full cause and effect of this reduction. It is further complicated by the fact that the fishery in 1988 and 1989 was almost entirely prosecuted on the spawning concentration in Div. 3K (if the EEC reported catch in Div. 3L is ignored). As a result, it may be too early to determine if the present TAC is having a detrimental effect on this component of the resource. If the present fishing practice continues and the future surveys and age structures remain stable, one may conclude the present TAC to be appropriate if it reflects catch; if not, alternative measures would be required.
