STATUS OF THE ATLANTIC COD STOCK ON GEORGES BANK IN UNIT AREAS

5 Zj and $5 \mathrm{Zm}, 1978-88$
by

J. J. Hunt<br>Marine Fish Division<br>Biological Sciences Branch<br>Department of Fisheries and Oceans Biological Station<br>St. Andrews, New Brunswick EOG 2X0

${ }^{1}$ This series documents the scientific basis for fisheries management advice in Atlantic Canada. As such, it addresses the issues of the day in the time frames required and the Research Documents it contains are not intended as definitive statements on the subjects addressed but rather as progress reports on ongoing investigations.

Research Documents are produced in the official language in which they are provided to the Secretariat by the author.
${ }^{1}$ Cette série documente les bases scientifiques des conseils de gestion des pêches sur la côte atlantique du Canada. Comme telle, elle couvre les problèmes actuels selon les échéanciers voulus et les Documents de recherche qu'elle contient ne doivent pas être considérés comme des énoncés finals sur les sujets traités mais plutôt comme des rapports d'étape sur les études en cours.

Les Documents de recherche sont publiés dans la langue officielle utilisée par les auteurs dans le manuscrit envoyé au secrétariat.

## Abstract

A newly defined management unit for the Atlantic cod stock in unit areas 5Zj and 5Zm was the basis for a review of stock status for 1978-88. Total landings peaked at 26000 t in 1982, have averaged about 16000 t and were 20368 t in 1988. Canada accounts for about $65 \%$ of the total catch. In 1988, most of the catch was made up of the 1985 and 1983 year-classes. No survey indices specific to 5 Zj and 5 Zm are available for this stock. Catch per tow in both the USA spring and fall survey of Division 5Ze increased in 1988 but remain at relatively low values. The canadian spring survey catch per tow has been increasing since 1987. Standardized C/E for Canadian and USA otter trawlers have shown a general decline since 1978. Uncertainties regarding input data preclude a detailed analysis of stock status at the present time. However, results of SPA using an average F in 1988 indicate fishing mortalities 2-3 times $\mathrm{F}_{0,1}$ are associated with recent catches of 15000-20000 $t$ and the fishery is largely dependent on recruiting year-classes. Reduction of total catch by a factor of 2 in 1990 is required if $\mathrm{F}_{0.1}$ management objectives are to be approximated.

## Résumé

La création d'une nouvelle unité de gestion du stock de morue de l'Atlantique dans les secteurs 5 Zj et 5 Zm a donné lieu à une êtude de l'état des stocks de 1978 à 1988. Les débarquements totaux ont culminé à 26000 t en 1982, pour s'établir en moyenne à 16000 t ; en 1988 , ils atteignaient 20368 t. La part canadienne des prises totales est d'environ $65 \%$. En 1988, la majeure partie des prises se composait de poissons appartenant aux classes de 1985 et 1983. Aucune donnée de recherche propre aux secteurs 5 Zj et 5 Zm n'existe pour ce stock. Il ressort des relevês de recherche effectuées par les Etats-Unis dans la sous-division 5 Ze au printemps et à l'automne que les prises par trait ont augmenté en 1988, tout en conservant une valeur relativement faible. Les prises par trait effectuées lors des relevés de recherche canadiennes du printemps ont augmente depuis 1987. Les PUE normalisées des bateaux canadiens et américains pêchant au chalut à panneaux dénotent une régression générale depuis 1978. L'incertitude au sujet des intrants empêche de réaliser une analyse détaillé de l'état des stocks pour le moment. Toutefois, les résultats des ASP fondées sur un F moyen en 1988 révèlent que les prises récentes de 15000 à 20000 t correspondent à des taux de mortalité équivalent à deux or trois fois $F_{0.1}$, et que la pêche dépend largement des classe d'âge recrutées. Il s'avère nécessaire de réduire les prises totales par un facteur de 2 en 1990 si l'on veut approacher des objectifs de gestion correspondant a $\mathrm{F}_{0.1}$.

## Introduction

The cod fishery in Division 5Z' and Subarea 6 has been managed independently by Canada and the USA since 1978. Canada recommended TAC's for 1978-84, while the USA has followed their Groundfish Management Plan since 1981. Canada set Canadian quotas for 1985-88.

Hunt and Waiwood (1984, 1985) and Hunt and Gavaris (1986), in reviews of stock status, suggested fully recruited fishing mortalities well above the $\mathrm{F}_{\text {max }}$ of 0.25 since 1983. In the most recent assessment of this stock, Hunt (1988) reported a fully recruited fishing mortality of 0.8 in 1987 for the total Division $5 Z$ plus Subarea 6 area.

The present report incorporates 1988 commercial catch data and research survey results to estimate stock status for the 1978-88 time period in the two unit areas 5 Zj and 5 Zm . Definition of this management unit is based on analysis of tagging results as well as commercial and survey catch distribution and more recent tagging studies (see Appendix I).

Cod are taken by both Canada and the USA in unit areas 5Zj and 5Zm and all data relating to USA catches, C/E and research vessel surveys were provided by the National Marine Fisheries Service (NMFS) through Dr. Fred Serchuk at the Woods Hole, Mass., Laboratory.

## Trends in Reported Landings

Catches from 52 Z and 5 Zm are thought to be under- or mis-reported prior to 1978 and estimates of population status prior to this time are suspect (Hunt, 1987). Catch statistics since 1977, when foreign fleets were excluded from the 200 mile economic zones of Canada and the USA, are thought to be more reliable. There have been no reported landings by foreign fleets since 1978.

Annual Landings
The USA has been the main harvester of cod in Division $5 Z$ and Subarea 6. Total landings declined to about 20000 t in 1976 but then increased to the maximum recorded value of 57195 t in 1982. Catch in 1988 is estimated to be about 44800 t (USA 32100 t and Canada 12700 t).

Reported landings by Canada are confined to 5Zj and 5Zm and, since 1985, to the Canadian zone of these two unit areas. USA catches are taken throughout the 5Ze area with peak catches in 5Zeg and are summarized by unit area in Table 1.

Fishery by Country and Gear
The USA cod fishery in 5Zj and 5Zm is almost exclusively by otter trawlers. Catches peaked at about 10500 t in 1984, fell to about 5000 t in 1987 and increased to about 7600 t in 1988.

Canadian catches of cod are taken on the "Northeast Peak" of Georges Bank primarily between April and November. Landings have been
dominated by otter trawlers, except for 1984 (Table 2, Fig. 1). In 1987, both otter trawl and longline catches increased ( $22 \%$ and $60 \%$, respectively) over 1986 and the catch by gillnet increased $300 \%$ to $1155 t$, the highest in the time series. In 1988, otter trawlers, longliners and gillnetters accounted for $60 \%$, $35 \%$ and $5 \%$, respectively, of the $12700 t$ catch.

Catches by Canada and the USA in 5 Zj and 5 Zm for 1978-88 are summarized in Table 3 and in Figure 2. Catches peaked at 26000 t in 1982, averaged to about 16000 t between 1983-87 and increased to 20000 t in 1988. Since 1985, Canada has taken about 65\% of the total catch.

## Age Composition of the Commercial Catch

Sampling Intensity
Sampling coverage of the Canadian fishery prior to 1985 averaged about one sample per 1000 t landed. In 1985, 18 samples were collected, 19 in 1986 with a substantial increase to 33 samples in 1987 and 40 in 1988. Prior to 1978, sampling levels for Canadian catches were very low and it is unlikely that reliable estimates of removals at age could be obtained.

Age Composition
Canadian samples were used to obtain statistics by age according to the method described by Gavaris and Gavaris (1983). The bias introduced by applying otter trawl length frequencies to partition longline catches may be significant in years lacking samples for this gear. A summary of catches and samples used to estimate removals at age for 1988 is given Table 4. Percent age composition of Canadian catches are shown in Table 5. The 1985 year-class accounted for $66 \%$ of the catch in numbers and $45 \%$ in weight.

For the length weight relationship, values for $a$ and $b$ were derived from Canadian commercial sampling data. With round weight in kilograms and length in centimeters and these values were $\mathrm{a}=0.0000163$ and $\mathrm{b}=2.9048$ and they were used for both Canadian and USA sampling data.

Catch at age in the USA fishery for 1978-87 was estimated by prorating the reported total removals by the ratio of 57 j and 52 m to total catches for each year. This assumes a similar distribution for age groups throughout the total 52 area, although there is some evidence from surveys to suggest that differences between the eastern and western extremes of 52 exist. The extent of spatial differences in proportional catch at age will be assessed when USA sampling data specific to $5 Z j$ and $5 Z \mathrm{~m}$ are made available.

USA sampling for 1988 was not complete and consisted of one age key for the first quarter and length frequency samples for the first to third quarters. Catch at age in 1988 was initially estimated by quarter using the USA age key to partition length frequencies in quarters 1 and 2 and a Canadian age key for quarter 3 length frequencies. Quarter 3 samples were assumed to reflect catches in the second half of the year. However, examination of the key indicated only 2 age two fish from a total of over 400 age determinations, which resulted in a very low
estimate for catch at age two. Lengths corresponding to age two fish were evident in the length frequency data and it was therefore decided to partition the USA length frequency samples using Canadian age length keys (Figure 3).

In 1987 and 1988, percent catch at age by Canada and the USA were similar, although slightly greater numbers of the 1983 year-class at age 4 were reported in USA landings. Catch at age by country is given in Table 6.

Mean length and weight at age for Canadian samples are given in Tables 7 and 8, with the plus age group set to 115 cm and 15 kg , the approximate mean for ages 10-15.

## Stock Abundance Trends

Research Surveys
Random, depth-stratified bottom trawl surveys have been conducted by the USA in the autumn since 1963 and a spring survey was added in 1968. A summer survey was conducted from 1977 to 1981. Surveys in Subdivision 5Ze were completed by Canada in March 1986-89. Mean catch per tow in numbers by age group for each of the USA surveys is given in Table 9. No adjustment for different gears or vessels used during the time series has been made. The spring survey used the larger "Yankee 41" trawl from 1973-81 and considerable differences in catch per tow could be anticipated. Total net opening of the " 41 " trawl is about 1.7 times the opening of the "Yankee 36".

New trawl doors have been used for both spring and autumn surveys since 1985. Preliminary analysis of a study to develop conversion factors indicates the new trawl doors are more effective and would increase the catches of cod and haddock (pers. comm., Dr. F. Serchuk, NMFS). The value of the conversion factor has not been resolved and catches since 1985 should be considered an over-estimate relative to pre-1985 levels.

The spring survey has shown a decline in 0+ numbers between 1981-84, when the same sampling gear was used, and was at the lowest observed level in 1984. An increase in 1985 was followed by a decline in 1986 and the 1987 survey was the second lowest level since 1971. The 1988 survey increased, primarily due to the strong evidence of the 1985 year-class at age 3. The autumn survey has been relatively stable since 1982 with below average catches and shows a slight increase in the 1986 followed by a decline in 1987. The total catch per tow in 1988 increased and was similar to the 1986 value.

Survey catch rates are not available by unit area and it was necessary to assume constant relative density across the survey area in order to use the total index as an index for $5 Z j$ and 5Zm. USA strata 16-21 approximate the 5 Zj and 5 Zm area but the proportion of the catch by stratum given in Table 10a,b indicates variable contribution between 1970-86. Strata 16-21 account for about $50 \%$ of the total numbers but varied between 17 and $78 \%$ for 1978-86.

Canada has conducted a stratified random bottom trawl survey using a

Western IIa trawl in Subdivision 5Ze during March 1986-89. Results of this survey are given in Table 11 but catch levels are not directly comparable with USA catches due to the difference in vessel and gear type. The Canadian survey also uses different strata than the USA survey and incorporates the International boundary in strata margins. For the four survey years, abundance has been variable with similar numbers in 1986 and 1988 but lower in 1987. The stratified mean for 1989 was the highest in the series. The 1984 year-class at age 2 in 1986 seems strong but is below average in 1987 and 1988, suggesting that the 1986 catch is an over-estimate. The 1985 and 1987 year-classes account for most of the catch in numbers in 1989. There is not an appropriate subset of the Canadian strata which conforms to 5 Zj and 5 Zm and it will necessary to redefine boundaries for subsequent surveys to meet this requirement.

The stratified mean catch per tow for 5Ze in the USA fall survey and Canadian spring survey are summarized in Figure 4.

Commercial Catch Rates
Catch and effort statistics by month and gear, for the Canadian fishery, were derived from Table 5 of the NAFO/ICNAF Statistical Bulletins for 1967-83. Data for 1984-88 were obtained from the Canadian Department of Fisheries and Oceans. A multiplicative model (Gavaris, 1980) was used. All observations where either the catch was less than $10 t$ or the effort was less than 10 hours were excluded from the analysis.

Examination of the residuals from the preliminary unweighted analysis resulted in the exclusion of three observations: OTB2-4, April 1967; OTB2-2 December 1968; OTB2-2, October 1982. There were no annual trends in either month or gear residuals but observations with lower catch and effort were more variable. Therefore; a weighted analysis was applied. An iterative procedure described by Judge et al (1980) was used to estimate the weights based on the partitioning of residuals along a logarithmic (catch $x$ effort) scale. The analysis of variance from the weighted regression indicates that months do not account for much of the systematic variation. The coefficients for gears follow an intuitive pattern with larger vessels associated with greater fishing power.

The results of the analysis are shown in Table 12 in the re-transformed linear scale. Trends in the linear scale (Figure 5) indicate fairly low C/E in the mid-1970's with an abrupt increase in 1977 probably due to the recruitment of the 1975 year-class. This is followed by a general decline, although catch rates increased somewhat in 1981-82 and 1985, probably due to recruitment of the 1980 and 1983 year-classes, respectively. Both the 1986 and 1987 C/E decreased from 1985. The 1988 C/E was slightly higher compared to 1987. Total effort also peaked in 1983, declined until 1986 but increased in 1987 and remained high in 1988.

A 1978-87 subset of the Canadian total series was also examined. The shorter time series was assumed to minimize the effect of learning and potential improved efficiency which may have taken place in the early to mid $70^{\prime}$ 's when fleet expansion occurred. Results of analysis of this data set were similar to those obtained with the $1967-88$ series (Table 12).

Catch and directed effort ( $>50 \%$ cod) for USA otter trawlers for 1979-87 were available by unit area and a standardized catch rate was estimated using the multiplicative model. Results are given in Table 12 and indicate substantial reduction in C/E between .1980 and 1987.

Comparison of the three catch rates examined is given in Figure 5. The 1967-88 and 1978-87 Canadian series show similar trends with a general decline since 1978. The USA C/E is less than $20 \%$ of the Canadian C/E but shows a similar decline and was at its lowest value in 1988. The abrupt increase in Canadian C/E observed in 1977 is not supported by an equivalent increase in stock biomass and may reflect improved efficiency. Therefore, it is considered more appropriate to use only the post-1978 commercial indices of abundance.

## Sequential Population Analysis (SPA)

Catch at age may be inaccurate due to spatial differences in the proportion at age in the USA fishery. Research survey indices are not specific to the management unit. Examination of Canadian C/E and fishable biomass estimated from the converged part of the population matrix (1978-83) indicates poor correlation. These uncertainties in data preclude an analytical assessment of stock status in $5 Z \mathrm{Zj}$ and 5 Zm at the present time. However, to obtain an overview of stock status, the ADAPT model (Gavaris, 1988) was used with the following formulation:

## Parameters

- Year-class estimates $\quad N_{i}, 1988 \quad i=1$ to 5
- Calibration constants for RV numbers $K_{i} \quad i=1$ to 5

Structure

- natural mortality was set to 0.2
- error in catch at age assumed negligible
- F for agegroups 6-9 in 1988 and at age 9 for other years was calculated as the weighted $F$ for ages 3-5
- intercepts not included

Input
$-C_{i, t} \quad i=1$ to 9, $t=1978$ to 1988
$-\mathrm{RV}_{i, t} \quad \mathrm{i}=1$ to $9, \quad \mathrm{t}=1978$ to 1988
Objective function

- minimize $\quad\left\{\left(o b s\left(\ln R V_{i, t}\right)-\text { (pred }\left(\ln R V_{i, t}\right)\right)^{2}\right.$
- beginning of year estimates of population size were fished down to coincide with the median month of the survey (October)

## Summary

```
- number of observations = 55
- number of parameters = 10
```

The model converged and gave significant estimates for all five slopes but gave significant population estimates only for ages 3-5. Fully recruited fishing mortality (3+) was estimated at 0.667 in 1988. Between 1978 and 1987, fully recruited fishing mortality fluctuated around a mean of about 0.5.

Mean SPA Run
To provide a rough approximation of stock status, an SPA was run with an $\mathrm{F}_{\mathrm{t}}$ of 0.5 , the approximate mean for 1978-87, as indicated from the above ADAPT run.

Fishing mortality (3+) averaged to 0.35 between 1978-81 but increased to an average of 0.48 in the 1983-87 time period. Fishing mortalities reached a high of 0.55 in 1985 and have exceeded $F_{\max }$ over the entire time series as shown in Figure 6.

Estimated 1+ population numbers ranged from 30-38 million for 1978-82 but decreased to 24 million in 1983 and have remained low since with some variability associated with recruitment. Numbers at $3+$ are strongly influenced by recruitment. Similar results are apparent in the estimate of $3+$ population biomass, which has varied between 23000 and 42000 t . Estimated recruitment at age 1 and 3+ numbers are shown in Figure 7. Estimated $3+$ biomass is given in Figure 8.

## Yield per Recruit Analysis

Mean weight at age for ages $1-15$ were derived from Canadian commercial catch samples. Very few fish older than 15 years are taken in the fishery and the level of sampling for these agegroups is inadequate to provide reliable estimates of weight at age.

Partial recruitment was determined from the fishing mortality matrix for 1978-86 for ages 1 and 2 with full recruitment assumed for ages 3 and older. Increased effort on strong recruiting yearclasses is evident in this fishery and partial recruitment at age two varies between 13 and 65 percent (Figure 8). The overall mean partial recruitment at age two for 1978-86 was about $36 \%$.

Results of yield per recruit analysis, using the Thompson and Bell model, indicate $F_{0.1}$ is 0.166 and $F_{\text {max }} 0.283$ with corresponding yields of 1.656 and $1.766 \mathrm{~kg}_{\mathrm{g}}$, respectively. With geometric mean recruitment at age 1 of about 9 million, the long term yield from this stock is about 14900 t. For most cod stocks in the Northwest Atlantic, $\mathrm{F}_{0.1}$ exploitation occurs at a fully recruited fishing mortality of about 0.20 .

## Prognosis

Assumptions used to generate input values cause the estimated stock size at the beginning of 1989 to have a degree of uncertainty
which limits the validity of catch projections for 1990. Projected catches for 1989 are 8000 t for Canada (Canadian allocation) and 7000 t for the USA (assumed the same as in 1988) which would result in a total catch of 15000 t , well above the $\mathrm{F}_{0.7}$ exploitation yield. Fishing mortalities and associated catches since 1978 have been 2-3 times the $\mathrm{F}_{0.1}$ value which imply it would be necessary to reduce total catches (Canadian and USA) by 2-3 times to achieve $\mathrm{F}_{0.1}$ exploitation.

Management Considerations
Implementation of a new management unit (5Zj and 5Zm) is based on an analysis of catch, effort, tagging and biological parameters (Appendix 1). Results of this study indicate that the 5 Zj and 5 Zm area is sufficiently isolated from adjacent areas to justify definition of the management unit.

Reducing catches by Canada to a level consistent with an F0.1 management strategy would not result in substantial increases in yield to the Canadian fleet and any decrease in effort by Canada would result in increased catch rates for the USA. Reduced effort by Canada could help rebuild the stock, but this is likely to be negated by increased effort by the USA in response to increased catch rates. The 5 Zj and 5 Zm management unit includes catches by both Canada and the USA and it will be necessary to develop consistent management.

## Acknowledgments

The co-operation and assistance provided by the National Marine Fisheries Service through Drs. Fred Serchuk and Ralph Mayo in compiling USA sampling, catch and effort data for the $5 Z \mathrm{~J}$ and 5 Zm area is very much appreciated. These data will continue to be an essential element for provision of advice on this stock.

a. Spring and autum cover LSA strata 13-25
b. Catch per tow at age for $1963-69$ obtained by applying $1970-81$ age-length keys to stratified ean catch
per tow at length distributions frow each survey.
C. Spring surveys during 1973-81 were accompliched with a "Yankee 41" trawl. In all other years, spring surveys were accooplished with a "Yankee 36 " trawl. No adjusteents have been ade for these gear differences.
d. Excludes unusually high catch of $1894 \operatorname{cod}(2558 \mathrm{~kg})$ at Station 230 (Strata tom 20-4)
e. Excludes unusually high catch of $1032 \operatorname{cod}(4096 \mathrm{~kg})$ at Station 323 (Strata tow 16-7)
F. Prelicinary estimate from length distribution

Table 10(a). Proportional distribution of cod by USA strata derived from USA spring surveys.

Report of MPD Special Meeting on the Groundfish Management Units in the Gulf of Maine Area

> Conference Room Biological Station St. Andrews, N.B.

12 April 1989

## Introduction

The Canadian fisheries management system currently incorporates the Canadian part of Subdiv. 5Ze (i.e. Subdiv. 5Zc) in the following management units for cod, haddock and pollock:

| Cod | Divisions 5Z-6 |
| :--- | :--- |
| Haddock | Subarea 5 |
| Pollock | Divisions 4VWX + 5 |

The rationale for these was established in the ICNAF era. Since then, the establishment of domestic management systems in both Canada and the USA (1977) coupled with definition of a new international boundary (1984) has created the need for a re-examination of the management unit definition. A review of these was conducted under the auspices of CAFSAC in 1986. Although a number of modifications to management unit boundaries appeared possible, the process was not completed. More information is now available from tagging experiments and was examined along with previous results. A meeting of MFD staff was held in St. Andrews on 12 April 1989 to consider the available data, historical and current, relevant to the cod, haddock and pollock management units. This report summarizes the findings and rationale used in arriving at them.

## Georges Bank Cod

Canadian landings from NAFO Div. 5Ze are reported historically from unit area 5ZeJ and 5Zem with over 90\% of the catch coming from the North Bast peak in recent years (Pigure 1). About 70\% of the USA 5Ze catch is taken in unit areas 5Zeg, 5Zeh, SZen and 5Zeo with over 40X in 5Zeg alone. There is definite evidence for a discontinuity in the landings from the Bank between these four unit areas in the west and the two unit areas on the North Bast peak in the east. Canadian catch in 4 X is spread across the entire division with substantial catches in 4Xp (Browns Bank).

Canadian and USA research surveys of 5Ze indicate videspread distribution of cod over the area. However, two centres of abundance are apparent with one in the 5Zef,m area and the other in the South Channel area. Annual and seasonal variation in the distributions occurs with more dense aggregations in $5 Z e j, m$ in the late winter period. These results indicate that a variable
proportion of the 5 ze population is found in the Canadian zone which requires further study.

Analysis of tagging data collected in the early 1960s suggests the presence of four groups of cod - offshore $4 \mathrm{X} / 52$ (Browns and Georges banks), inner Gulf of Maine, New England/South Channel and finally New Jersey. Little interaction between the Georges Bank group and that to the west of the South Channel is evident.

These findings are confirmed and amplified by more recent work conducted in 1979-87. Results indicate that most fish released in 4X were recovered in 4X with widespread movement between unit areas. Limited movement to the North East peak of Georges Bank ( 5 Zej ) was also evident. The majority of the tags released in 5 Zej were recovered in 5Zej and 5Zem with little movement to the west. This is in agreement with previous tagging studies. Movement to 4X (primarily Browns Bank) was also evident. Quantification of the extent of these movements will require further analysis, however, it is not expected that this will change the conclusions.

Sufficient differences exist in growth rates between Georges and Browns banks to preclude treating them with one management strategy.

There are a number of centres of spawning in the Gulf of Maine area. Based on distributions of eggs, larvae and juveniles it is apparent that spawning occurs on Browns Bank, northeast part of Georges Bank, along the New England coast and in the Cape Cod areas.

In summary, the examination of the data collected to date suggests that the $5 Z+6$ management unit should be divided into two as follows:

- 1. Unit areas 5Zej and 5Zem

2. Unit areas 5Zeg, 5Zeo, 5Zeh and 5Zen plus areas to the south in 5ZW and Subarea 6.

There is insufficient evidence at this time to associate 5Zej cod with those in 4 X . The separation of Management Unit $5 Z+6$ into two components, one on the northeast peak of Georges Bank and the other in the South Channel and vast, has implications for management of the resource. Hovement of cod across the International Boundary occurs, and it would be inappropriate to consider this line as a boundary for stock separation without quantifying the degree of movement. It is planned to conduct further research on the degree of movement both within 5Ze and between it and 4X. Hovever, most of the cod associated with the northeast peak of Georges Bank are contained within unit areas 5zej, m and it is, therefore, recomended that these two areas be used for the management of the resource.
