¹This series documents the scientific basis for fisheries management advice in Atlantic Canada. As such, it addresses the issues of the day in the time frames required and the Research Documents it contains are not intended as definitive statements on the subjects addressed but rather as progress reports on ongoing investigations.

Research Documents are produced in the official language in which they are provided to the Secretariat by the author.

¹Cette série documente les bases scientifiques des conseils de gestion des pêches sur la côte atlantique du Canada. Comme telle, elle couvre les problèmes actuels selon les échéanciers voulus et les Documents de recherche qu'elle contient ne doivent pas être considérés comme des énoncés finals sur les sujets traités mais plutôt comme des rapports d'étape sur les études en cours.

Les Documents de recherche sont publiés dans la langue officielle utilisée par les auteurs dans le manuscrit envoyé au secrétariat.

Abstract

The major component of this fishery was a purse seine fleet of five vessels which reported landings of 2078 mt in a 2-wk period from Nov. 27 to Dec. 7, 1989. Fishery Officer hails corresponded closely to these catches and the decrease of about 500 mt over 1988 was attributed to a late start in the fishery. Logbooks accounted for 64% of purse seine catches and showed a similar spatial distribution to previous years. Other catches of herring by inshore gear accounted for 114 mt, a decrease from 1988 but within the range of recent years' landings. Biological sampling showed that the 1983 year-class (age 6) dominated the catch in numbers and weight for the fourth successive year (since age 3). A re-evaluation of tagging results did not change the conclusion that the winter fishery in 4Vn exploits a mixture of stocks and that, as a result, an analytical assessment of 4Vn herring is not possible.

Résumé

La principale composante de cette pêcherie était une flotte de cinq bateaux de pêche à la senne coulissante qui a signalé des débarquements de 2 078 t au cours d'une période de deux semaines entre le 27 novembre et le 7 décembre 1989. Les communiques des agents des pêches correspondaient étroitement à ces prises et la diminution d'environ 500 t par rapport à 1988 a été attribuée à une lent départ de la pêche. Les journaux de bord rendent compte de 64 % des prises à la senne coulissante et indiquent une répartition spatiale semblable à celle des années précédentes. La pêche au hareng par des engins côtiers a donné lieu à ces prises de 114 t, une diminution par rapport à 1988, mais une valeur qui se situe dans la gamme observée pour les débarquements au cours des dernières années. Un échantillonnage biologique a révélé que la classe d'âge 1983 (âge 6) a dominé les prises en nombre et en poids pour la quatrième année consécutive (depuis l'âge 3). Une réévaluation des résultats du marquage n'a pas changé la conclusion selon laquelle la pêcherie d'hiver dans la zone 4Vn exploite un mélange de stocks et, en conséquence, une évaluation analytique du hareng de 4Vn est impossible.

Introduction

History of the Fishery

The Sydney Bight herring fishery has two components. A relatively small (less than 500 t yr⁻¹; Table 1) trap and gillnet fishery has historically taken place inshore, including the Bras d'Or Lakes, during the spring and summer. A large vessel mobile fishery began in 1968. This was dominated by foreign fleets for the first 2 yr but subsequently has been almost exclusively a Canadian purse seine fishery operating during the late autumn and early winter months. Annual landings peaked at 17,547 t in 1972/73 but, with TAC regulation, have been less than 5000 t since 1978 (Table 1).

A review of statistics resolved a discrepancy concerning landings from the 1988 fishery noted in the previous Research Document (Stephenson and Power 1989). The total of 4837 t included some duplication and was later revised to 2572, which matched purchase slips (A. MacIsaac, DFO, pers. comm.).

Stock Structure

Previous tagging studies (summarized by Simon and Stobo 1983) indicated that the winter purse seine fishery exploits overwintering herring which are a mixture of Gulf of St. Lawrence (4T), local (4Vn) and Nova Scotia (4WX) stocks. The relative affinity with other stocks was different in fish tagged at different locations within 4Vn. Of those tagged to the north and west of the area (north of Bird Island), a higher proportion was returned from area 4T; of those tagged in the southeast, a higher proportion was returned from area 4WX. Herring tagged during the spring fishery (April-May; St. Ann's Bay) were returned primarily from 4Vn (including Bras d'Or Lakes) but also from area 4T.

Description of the 1989 Fishery

Management Plan

The 1990 Scotia-Fundy Region Herring Management Plan limited the 4Vn purse seine fishery:

- (i) to the period Nov. 1, 1989-Mar. 1, 1990;
- (ii) to a TAC of 4200 t (by "Gulf-based" vessels); and
- (iii) to the area north and west of a line drawn from Pt. Aconi in Cape Breton to the 3Pn/4Vn intersection.

Inshore (trap and gillnet) effort was not under TAC management, except that no effort increase was allowed.

Catch and CPUE

Monthly landings by gear type are presented in Table 2.

The purse seine fishery involved five vessels and took place between Nov. 27 and Dec. 7, 1989. Total reported landings amounted to 2078 t, a reduction of almost 500 t from 1988 and the lowest in 20 yr. Fishery Officer hails (from quota reports = 2096 mt) support this figure. This decrease is attributed to the late start of the fishery.

A total catch of 114 t was recorded from inshore gear in 1989, approximately one-third that of the previous year but within the range observed over the past decade.

Logbook coverage of the purse seine fishery included all vessels but accounted for only 64% of the total nominal catch (Table 3).

The spatial pattern of catch (by 10' square) was calculated from logbook information and is shown in Fig. 1. As in recent years (1983-present), catches were concentrated along the north shore of St. Ann's Bay, around Cape Smokey. The Pt. Aconi line of the Management Plan restricts purse seine activity to the northern section of 4Vn, but Stobo and Simon (1982) pointed out that the centre of the fishery had already shifted northward over the historical period of the fishery and before the line was imposed.

The purse seine fishery was concentrated within a 2-wk period. Biological sampling was adequate for a single age length key to generate numbers at age. Three detail samples resulted in 125 fish aged and a catch per detail sample ratio of 16.6 (t/detail fish).

Monthly catch numbers and weight at age are presented in Table 4. The 1983 year-class (age 6) again dominated in number and also in weight. The historical catch at age matrix is given in Table 5, and mean weights at age weighted by numbers caught in Table 6.

Recent reanalysis of tagging results from the late 1970s and early 1980s (W.T. Stobo, S.C. Courtenay and J. Gagne, DFO, pers. comm.) confirmed an earlier conclusion that the summer fixed gear fishery exploits local stocks but that the winter purse seine fishery is on a mixture of stocks. Although regulatory restriction of the fishery to the northern part of 4Vn undoubtedly increases the 4T and reduces the 4WX contribution, the proportions cannot be quantified from existing tagging data. As stated previously (since 1981), there is insufficient information to assess local stocks supporting the inshore fishery, and because of stock mixing in the winter fishery, an analytical assessment of 4Vn herring is not possible.
