# Effects of Changing Fishing Mortality on Atlantic Salmon (Salmo salar L.) Egg Deposition in Gander River 

by

T. R. Porter and M. F. $0^{\prime}$ Connell<br>Science Branch<br>Department of Fisheries and Oceans<br>P. O. Box 5667<br>St. John's, Newfoundland A1C 5X1

1 This series documents the scientific basis for fisheries management advice in Atlantic Canada. As such, it addresses the issues of the day in the time frames required and the Research Documents it contains are not intended as definitive statements on the subjects addressed but rather as progress reports on ongoing investigations.

Research Documents are produced in the official language in which they are provided to the Secretariat by the author.

1 Cette série documente les bases scientifiques des conseils de gestion des pêches sur la côte atlantique du Canada. Comme telle, elle couvre les problèmes actuels selon les échéanciers voulus et les Documents de recherche qu'elle contient ne doivent pas être considérés comme des énoncés finals sur les sujets traités mais plutôt comme des rapports d'étape sur les études en cours.

Les Documents de recherche sont publiés dans la langue officielle utilisée par les auteurs dans le manuscrit envoyé au secrétariat.

#### Abstract

Assessments of the Gander River salmon populations indicated that from 1989-1991 the Gander River only received about $35 \%$ of its required egg deposition. An evaluation of the effects of changing the fishing mortality in the commercial and recreational fisheries indicated the egg deposition would be: 1) $40 \%$ of requirements if only the recreational fishery is closed; 2) $60 \%$ of requirements if only the commercial fishery in Gander Bay is closed; 3) 72\% of requirements if the commercial fishery in Gander Bay and the recreational fishery are closed; 4) $87 \%$ of requirements if all commercial fisheries are closed; and 5) $100 \%$ of requirements if all the commercial and recreational fisheries are closed. These evaluations assume that the total population size would be similar to the average size observed for 1989-91.

#### Abstract

Résumé Une évaluation des populations de saumon de la rivière Gander a révélé qu'entre 1989 et 1991 , la ponte n'a représenté que 35 p .100 des besoins. On a établi qu'en modifiant la mortalité due à la pêche commerciale et sportive, la ponte s'établirait comme suit : 1) 40 p .100 des besoins si on fermait seulement la pêche sportive; 2) 60 p .100 des besoins si on fermait la pêche commerciale dans la baie de Gander seulement; 3) 72 p. 100 des besoins si on fermait la péche commerciale dans la baie de Gander et la pêche sportive; 4) 87 p. 100 des besoins si on fermait toute pêche sportive et 5) 100 p .100 des besoins si on fermait toute pêche commerciale et toute pêche sportive. Ces chiffres sont fondés sur l'hypothèse d'un population comparable à la moyenne de 1989 à 1991.

## Introduction

The Atlantic salmon (Salmo salar) population entering the Gander River has declined during the 1980 's, and from 1989 to 1991 , only $33-36 \%$ of the egg deposition requirement ( $46.211 \times 10^{\circ}$ ) has been achieved ( $0^{\prime}$ Connell and Ash 1992). $0^{\prime}$ Connell and Ash (1992) also concluded that the commercial fishery in Gander Bay contributed to this decline.

This paper evaluates the possible benefits that changing the fishing mortality may have on increasing egg deposition in the Gander River. Five scenarios for reducing fishing mortality are considered, namely:

1. Closing the recreational fishery in the Gander River.
2. Closing the commercial fishery in Gander Bay, with the recreational fishery left open.
3. Closing the commercial fishery in Gander Bay and the recreational fishery in Gander River.
4. Closing all commercial fisheries exploiting salmon of Gander River-origin, with the recreational fishery left open.
5. Closing all commercial fisheries exploiting salmon of Gander River-origin and also closing the recreational fishery on Gander River.

## Methods

## Data

Commercial catch statistics for five communities in Gander Bay (Fig 1), 1974-91, were available from the Fisheries Statistics and Systems Branch of the Department of Fisheries and Oceans. Recreational catch statistics for the Gander River are presented in Table 1. The number of salmon entering the river and estimates of numbers of spawners and egg deposition are from $0^{\prime}$ Connell and Ash (1992).

Biological characteristics for Atlantic salmon in the Gander River are from $0^{\prime}$ Connell and Ash (1992). Biological characteristics of salmon caught in the commercial fishery in Gander Bay are from samples taken in the commercial fishery at Fredericton in 1989 (Table 2). Small salmon refers to salmon < 63 cm for salmon in the river and salmon $<2.68 \mathrm{~kg}$ in the commercial fishery. Large salmon refers to salmon $\geq 63 \mathrm{~cm}$ for salmon in the river, and $\geq 2.68 \mathrm{~kg}$ in the commercial fishery.

## Egg deposition from reducing fishing mortality

The effect that each of the five scenarios, referenced above, would have on increasing egg deposition in the Gander River was evaluated by applying the
closure in scenarios 1, 2, and 3 to landings during the period 1974-91 and the closures in scenarios 4 and 5 to landings during the period 1989-91.

Scenario 1: Closure of the Recreational Fishery
The potential effect that closing the recreational fishery 1974-91 would have had on the egg deposition was calculated by using the following formula:

1) $E_{r}=\left[\left(A_{g} * W_{g} * S_{g}\right)+\left(A_{1} * W_{1} * S_{1}\right)\right] * R_{f}$
where: $E_{r}=$ Potential egg deposition from closure of the recreational fishery
$A_{g}^{r}=$ Angling catch, in numbers, of small salmon
$\mathrm{W}_{\mathrm{g}}^{\mathrm{g}}=$ Mean weight of small salmon
$S_{\mathrm{g}}^{\mathrm{g}}=$ Percent female of small salmon
$A_{1}=$ Angling catch, in numbers, of large salmon
$W_{1}^{1}=$ Mean weight of large salmon
$S_{1}=$ Percent female of large salmon
$R_{f}=$ Relative fecundity (eggs $/ \mathrm{kg}$ )
The relative fecundity for all sizes of salmon was assumed to be $1,665 \mathrm{eggs} / \mathrm{kg}$ ( $0^{\prime}$ Connell and Ash, 1992)

Scenario 2: Closure of the commercial fishery in Gander Bay and the recreational fishery in Gander River left open

The potential effect that closing the commercial fishery in Gander Bay, 1974-91, would have had on the egg deposition was calculated by using the following formula:
2) $\mathrm{E}_{\mathrm{b}}=\left[\left\{\left(\mathrm{C}_{\mathrm{g}} * \mathrm{P} * \mathrm{~S}_{\mathrm{cg}}\right)\left(1-\mathrm{U}_{\mathrm{g}}\right)\right\}+\left\{\left(\mathrm{C}_{1} * \mathrm{P} * \mathrm{~S}_{\mathrm{cl}}\right)\left(1-\mathrm{U}_{\mathrm{l}}\right)\right\}\right] * \mathrm{R}_{\mathrm{f}}$
where: $\mathrm{E}_{\mathrm{b}}=\begin{aligned} & \text { Potential egg deposition from salmon which would have been } \\ & \text { released from the commercial fishery in Gander Bay }\end{aligned}$
$\mathrm{C}_{\mathrm{g}}=$ Commercial catch in kg of small salmon in Gander Bay
$\mathrm{p}^{\mathrm{g}}=$ Proportion of salmon that are Gander River-origin
$S_{c g}=$ Percent females of small salmon in commercial fishery
$S_{c l}^{c g}=$ Percent females of large salmon in commercial fishery
$\mathrm{U}_{\mathrm{g}}^{\mathrm{cl}}=$ Exploitation rate on small salmon in the recreational fishery in Gander River
$U_{1}=$ Exploitation rate on large salmon in the recreational fishery in Gander River
$C_{1}=$ Commercial catch in kg of large salmon in Gander Bay
Three calculations were performed, assuming that the proportion of Gander River-origin salmon in the catches in Gander Bay was either 1.0, 0.75 , or 0.50 .

The exploitation rates on small salmon in the recreational fishery were $0.153,0.149$, and 0.175 in 1989,1990 , and 1991 respectively, as calculated from data provided in $0^{\prime}$ Connell and Ash (1992). It was assumed that there was no angling mortality on large salmon, 1984-91. The mean exploitation rate
(0.159) for 1989-91 was assumed for all previous years for small salmon and for years prior to 1984 for large salmon.

Scenario 3: Closure of the commercial fishery in Gander Bay and the recreational fishery in Gander River

The potential effect of these closures when applied to 1974-91 can be derived making $U_{g}$ and $U_{1}=0$ (equation 2) and summing $E_{r}$ from equation (1) and $E_{b}$ from equation ${ }^{g}(2)$.

Scenario 4: Closure of all commercial fisheries exploiting Gander River-origin salmon and the recreational fishery in Gander River left open

The potential effect that closing all commercial fisheries harvesting salmon of Gander River-origin would have had on the egg deposition was calculated for 1989 , 1990, and 1991. These were years in which total escapements to the Gander River are known. The following formula was used:
3) $\mathrm{E}_{\mathrm{c}}=\left[\left(\mathrm{ES}_{\mathrm{g}} *\left(1-\mathrm{U}_{\mathrm{g}}\right) * \mathrm{~W}_{\mathrm{cg}} * \mathrm{~S}_{\mathrm{cg}}\right)+\left(\mathrm{ES}_{1} * \mathrm{~W}_{\mathrm{cl}} * \mathrm{~S}_{\mathrm{cl}}\right)\right] * \mathrm{R}_{\mathrm{f}}$
where: Ec = Potential egg deposition from salmon which would have been released from commercial fisheries
ES ${ }_{\mathrm{g}}=$ Additional escapement of small salmon
$E S_{1}^{\mathrm{g}}=$ Additional escapement of large salmon
$\mathrm{W}^{1}=$ Mean weight of small salmon released from commercial fisheries
$\mathrm{W}_{\mathrm{cl}}^{\mathrm{cg}}=$ Mean weight of large salmon released from commercial fisheries
The terms $E S_{g}$ and $E S_{1}$ are further defined:
4) $E S_{g}=\left(R E_{g} * 1 / U_{c g}\right)-R E_{g}$
5) $E S_{1}=\left(\mathrm{RE}_{1} * 1 / \mathrm{U}_{\mathrm{cl}}\right)-\mathrm{RE}_{1}$
where: $\mathrm{RE}_{\mathrm{g}}$ and $\mathrm{RE}_{1}=$ River escapement of small and large salmon respectively $\mathrm{U}_{\mathrm{cg}}^{\mathrm{g}}$ and $\mathrm{U}_{\mathrm{cl}}=\begin{aligned} & \text { Commercial exploitation rate of small and large salmon } \\ & \text { respectively }\end{aligned}$ respectively

The commercial exploitation rates were assumed to be 0.50 on small salmon $\left(U_{G g}\right)$ and 0.75 on large salmon ( $U_{c l}$ ). The biological characteristics of the addgtional fish released from the commercial fisheries were assumed to be the same as those derived from salmon sampled at Fredericton in 1989 (Table 2).

Scenario 5: Closure of all commercial and recreational fisheries exploiting salmon of Gander River-origin

The potential effect that closing all commercial and recreational fisheries harvesting salmon of Gander River-origin would have had on the egg deposition was also calculated for 1989, 1990, and 1991. The effects (E ) of closing all commercial fisheries was calculated using Equation (3) and setting $\mathrm{U}_{\mathrm{g}}$ at 0.0. The effect ( $\mathrm{E}_{\mathrm{r}}$ ) of closing the recreational fisheries was
calculated from Equation (1). The total potential egg deposition which could have occurred in 1989, 1990, and 1991 was determined by summing $E_{r}, E_{r}$, and the estimate of the egg deposition estimated by $0^{\prime}$ Connell and Ash (1992). ${ }^{\text {r }}$

## Results

There was a substantive increase in the commercial landings of small salmon in Gander Bay, beginning in 1981 (Table 1). The average landings increased from about $4.5 \mathrm{t}, 1974-83$, to about $12.6 \mathrm{t}, 1984-91$. The landings of large salmon tended to remain relatively constant over years. The landings of small salmon in the recreational fisheries declined from about 3,000 fish, 1974-83 to about 2,000 fish, 1984-91.

The potential annual effect that the various closures could have had on the egg deposition if applied during the period 1974-91, for scenarios 1, 2 , and 3, and 1989-91 for scenarios 4 and 5, are shown in Tables 3-7. These results are summarized below. For scenarios 2 and 3, the percent egg requirements are based on calculations using 0.75 as the proportion of the salmon in the commercial fishery in Gander Bay which were of Gander Riverorigin.

| Years | \% of egg requirements released from fisheries |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: |
|  | Scen 1 Close Rec | Scen 2 Close GB | $\begin{aligned} & \text { Scen } 3 \\ & \text { Close } \\ & \text { GB+Rec } \end{aligned}$ | Scen 4 Close Com | $\begin{aligned} & \text { Scen 5 } \\ & \text { Close } \\ & \text { Com+Rec } \end{aligned}$ |
| 1974-83 | 16 | 15 | 33 | - | - |
| 1983-91 | 9 | 30 | 45 | - | - |
| 1989-91 | 5 | 25 | 36 | 52 | 65 |

The above percentages are in addition to the egg deposition which actually occurred.

During the period 1989-91, the Gander River potentially could have achieved $87 \%$ of its egg deposition requirements if there was no commercial fishing mortality and the recreational fishing exploitation rate was 0.159 (Table 6). If both the commercial and recreational fisheries had been closed, about $100 \%$ of the egg deposition requirements could have been met (Table 7 ).

## Discussion

The decline in recreational fishery landings coincides with an increase in landings of small salmon in the Gander Bay commercial fishery (Table 1). The high percentage of previous spawners in the commercial fishery in Gander Bay and the similarity of the river ages of salmon sampled in the Gander Bay and Gander River suggests that the salmon in Gander Bay are probably local origin. The proportion of previous spawners, $50 \%$ for small salmon and $55 \%$ for large
salmon (Table 2) is higher than the $5-10 \%$ percent normally observed in the commercial samples taken at Twillingate, also in SFA 4 (Reddin pers. comm.). The river age of salmon sampled in Gander Bay ranged from 2 to 5 years with a mean river age of 3.5 years ( $9 \%$ river age 2 ) which is similar to the mean river age of 3.7 years for salmon sampled in the Gander River ( $0^{\prime}$ Connell and Ash, 1992). Since there are no other salmon rivers in Gander Bay, it is reasonable to assume that about $75 \%$ of the salmon caught in the commercial fishery in Gander Bay are of Gander River-origin.

The differences in mean weight of large salmon in the commercial fishery $(3.05 \mathrm{~kg}$ ) and in the river ( 3.41 kg ) (Table 2 ) is probably related to the small sample sizes. Whereas, the larger mean weight of small salmon in the commercial fishery is believed to be related to selectivity of the commercial fishery for larger fish (Table 2).

The increased fishing mortality in Gander Bay in the 1980's could have resulted in an average additional reduction of $15 \%$ (potential egg loss in 1974-83 minus loss in 1984-91) of the Atlantic salmon egg deposition requirements of the Gander River (Table 4).
$0^{\prime}$ Connell and Ash (1992) indicated that from 1979 to 1988 the Gander River received $60-65 \%$ of its egg deposition requirements. If the commercial fishery in Gander Bay had been closed, 1979-1988, 81-86\% of the egg deposition requirements could have been met (Table 4). A closure of both the commercial fishery in Gander Bay and the recreational fishery would have increased this percentage to about $100 \%$ of requirements (Table 5).

In recent years, 1989 , 1990, 1991, salmon egg depositions have only been $35 \%, 36 \%$, and $33 \%$ respectively, of requirements ( $0^{\prime}$ Connell and Ash, 1992). A closure of the commercial fishery in Gander Bay and the recreational fishery in the Gander River (scenario 3) could have increased the egg deposition to $88 \%$, $65 \%$, and $58 \%$ of egg deposition requirements for 1989, 1990, and 1991 respectively (Table 5). If all commercial fisheries were closed but not the recreational fishery (scenario 4), 1989-91, 86-89\% of the egg deposition requirements could have been met (Table 6). A closure of all commercial and recreational fisheries (scenario 5), 1989-91, could have resulted in 97-102\% of the egg deposition being met (Table 7).

The above exercises calculating potential additional returns to the Gander River should be considered to represent just one of many possible results. There is uncertainty in most of the parameter values used in the calculations, and a simulation approach may have yielded a somewhat different distribution of expected results. The final outcome, however, would probably be consistent; that is, major changes to current fishing strategies on the Gander River origin salmon population would be required in order to increase egg deposition levels necessary for rehabilitation of the stock

## Management Considerations for Restoring the Gander River Salmon Populations

Consideration needs to be given to whether the management objective is to restore the salmon population to the estimated productive capacity of the Gander River in one or two life cycles ( 5 or 10 years). It is recommended that if the objective is to restore the population in two life cycles, then the
management target should be to attain at least $75 \%$ of egg deposition requirements for each of the next 5 years and $100 \%$ of the target in years 6-10. If it is assumed that the population size during the first five year period will be similar to the size observed 1989-91, then it will be necessary to: close the commercial fishery in Gander Bay and the recreational fishery in Gander River; or 2) close all commercial fisheries exploiting Gander Riverorigin salmon, but not the recreational fisheries. Option 2 would be successful only if strict controls were placed on the recreational fishery and the illegal fishery, so that any benefits obtained from the commercial closure would not be lost.

If the objective is to restore the Gander River population in one life cycle, then all commercial and recreational fisheries would need to be closed.

The above approaches to restore the salmon populations assumes that there will be negligible bycatch and there will be no increase in illegal harvest. There are presently no reliable techniques available to estimate the population size of Atlantic salmon prior to returns to the river. Changes in natural mortality could have a substantive effect on variation in the returns to the river with any given egg deposition. In season assessments are required in order to insure management targets are met.

## Acknowledgements

We thank D. G. Reddin for providing the biological characteristics information from the commercial fishery at Fredericton, and J. B. Dempson for reviewing the document.
