# ASSESSMENT OF ATLANIIC SAIMON IN THE MARGAREE RIVER, NOVA SCOTIA, 1991 

by

G. Chaput, R. Jones, and L. Forsythe<br>Department of Fisheries \& Oceans<br>Science Branch, Gulf Region<br>P.O. Box 5030<br>Moncton, New Brunswick<br>E1C 9B6

${ }^{1}$ This series documents the scientific basis for fisheries management advice in Atlantic Canada. As such, it addresses the issues of the day in the time frames required and the Research Documents it contains are not intended as definitive statements on the subjects addressed but rather as progress reports on ongoing investigations.

Research Documents are produced in the official language in which they are provided to the Secretariat by the author.
${ }^{1}$ Cette série documente les bases scientifiques des conseils de gestion des pêches sur la côte atlantique du Canada. Comme telle, elle couvre les problemes actuels selon les échéanciers voulus et les Documents de recherche qu'elle contient ne doivent pas ètre considéres comme des énoncés finals sur les sujets traités mais plutôt conme des rapports d'étape sur les études en cours.

Les Documents de recherche sont publiés dans la langue officielle utilisee par les auteurs dans le manuscrit envoyé au secrétariat.

#### Abstract

The recreational catches of Atlantic salmon (Salmo salar) from the Margaree River between June 1 and Oct. 15, 1991, were estimated by creel survey at 391 1SW salmon ( $<63 \mathrm{~cm}$ fork length) and 596 MSW salmon released. The recreational fishery exploitation rate estimates, based on recaptures of salmon tagged and released at the estuary, were 0.19 for 1 SW salmon and 0.17 for MSW salmon. The estimated returns of Atlantic salmon to the Margaree River in 1991 were 1909 ( $90 \%$ C.I. 794 to 3891) 1SW salmon and 3484 ( $90 \%$ C.I. 1853 to 5785) MSW salmon, resulting in potential egg depositions by MSW salmon of $326 \%$ ( $90 \%$ C.I. $170 \%$ to $547 \%$ ) of target requirements ( $334 \%$ of target by 1SW and MSW salmon). Potential egg depositions have exceeded target requirements since 1985 ( $137 \%$ in 1985 to $1067 \%$ in 1990). The high densities of juvenile salmon ( 20.8 to 73.0 parr $/ \mathrm{m}^{2}$ ) in the Margaree River in 1991 are a reflection of the high spawning escapements achieved in recent years.

## RESUME

Les captures de Saumon atlantique (Salmo salar) de la pêche récréative de la rivière Margaree, pour la période du $1^{\text {ier }}$ juin au 15 octobre, 1991, ont été estimés par enquête à 391 saumons unibermarins récoltés (longueur à la fourche inférieur à 63 cm ) et 596 saumons pluribermarins relâchés. Les taux d'exploitation de la pêche récréative, estimés par la méthode de recaptures de saumons étiquettés dans l'estuaire de la rivière, s'elevaient à 0,19 pour les saumons unibermarins et 0,17 pour les saumons pluribermarins. Les retours de Saumon atlantique à la rivière Margaree en 1991 ont eté estimés à 1909 (I.C. $90 \% 794$ à 3891 ) saumons unibermarins et 3484 (I.C. $90 \% 1853$ a 5785 ) saumons pluribermarins. Les survivants de ces retours de saumons pluribermarins auraient contribués plus de $326 \%$ (I.C. $170 \%$ à $547 \%$ ) du niveau cible d'oeufs pour la rivière Margaree ( $334 \%$ du niveau cible par les saumons unibermarins et pluribermarins). Les dépots potentiels d'oeufs ont excédé au niveau cible depuis 1985 ( $137 \%$ en 1985 à $1067 \%$ en 1990 ). Les hautes densités des juveniles dans la rivière Margaree en $1991\left(20,8\right.$ a 73,0 tacons $/ \mathrm{m}^{2}$ ) sont dues aux niveaux elevés de géniteurs atteints récemment.

## INTRODUCTION

This is the $8^{\text {th }}$ assessment of the Margaree River Atlantic salmon (Salmo salar) resource. Previous assessments have been presented for 1983, and 1985 to 1990 (Chaput and Jones 1991a; Claytor and Chadwick 1985; Claytor et al. 1987; Claytor and Chaput 1988; Claytor and Jones 1990; Claytor and Leger 1986; Gray and Chadwick 1984).

The Margaree River is situated in Cape Breton Island, Inverness County, Nova Scotia (Statistical District 2, Salmon Fishing Area 18) (Fig. 1). The two principal branches, the Southwest Margaree and the Northeast Margaree, meet at Margaree Forks to form the Margaree River which flows into the Gulf of St. Lawrence. Most of the recreational fishery takes place in the Northeast Margaree and the Margaree River proper, although the Southwest Margaree is fished in the fall. The Margaree River salmon has traditionally been considered as having two run components, the summer run which for statistical purposes ends on August 31, and the fall run occurring from Sept. 1 onwards.

Since 1979, numerous regulatory restrictions have been imposed to increase the summer component of the salmon run (Chaput and Claytor 1988). Mandatory release of multi-sea-winter (MSW) salmon ( $\geq 63 \mathrm{~cm}$ fork length) angled before Sept. 1 has been in place since 1979. Since 1985, all MSW salmon have been released regardless of date of capture. There was a change in the angling season in 1991 relative to previous years; the angling season was extended from June 1 to Oct. 31, rather than closing on Oct. 15, except for waters upstream of Cranton Bridge which were closed to angling after Oct. 15. The season limit of 101 SW salmon ( $<63 \mathrm{~cm}$ fork length) kept per license, the requirement that all 1SW salmon kept be tagged, and mandatory MSW salmon hook and release regulations were maintained. Restrictions on the commercial fishery were introduced in 1984 through a season reduction from 8 weeks to 3 weeks followed by closure of the fishery in 1985. The commercial fishery of Salmon Fishing Area 18 has remained closed since. Commercial landings prior to 1985 are summarized in Claytor and Jones (1990).

Some of the changes in this assessment relative to the 1990 assessment include:

- the method of estimating river catch using the creel catch estimate,
- the estimation of an integrated exploitation rate applied to angling catches in summer and fall,
- the use of "bootstrap" techniques for obtaining non-parametric estimates of variance for several parameters, and
- the use of simulations to generate estimates of catch, returns and escapements with associated confidence intervals for the estimators.

The results of electrofishing surveys are presented and used as indicators of past spawning escapements and to evaluate past and present habitat saturation by the juveniles in the Margaree River.

The angling catches from other Gulf Nova Scotia rivers, based on license stub returns are presented.

## MATERIALS AND METHODS

## Estimates of harvests and catches

Recreational catch estimates were obtained from three sources.

1. Fisheries officers from the Dept. of Fisheries and Oceans (DFO) at Margaree Forks, Nova Scotia,
have provided estimates of angling catch for the period 1947 to 1991 . MSW salmon hook and release estimates were not provided in 1991.
2. Recreational catches, since 1984, have been estimated from license stub returns (LIC) (O'Neil et al. 1985, 1986, 1987, 1989, 1991). Catch estimates for 1989 and 1990, and preliminary estimates for 1991 were obtained from S. O'Neil, DFO Halifax, Nova Scotia. The estimation procedures for the LIC data are outlined in O'Neil et al. (1991). Anglers are only required to report the number of MSW hooked and released from a given river for the entire season, therefore, seasonal breakdowns are not possible.
3. Angling catch was estimated by creel surveys, designed by DFO Science Branch, for 1987 to 1991. The creel survey method used in 1991 was identical to the 1990 "bus route" access point survey (Robson and Jones 1989) combined with lattice sampling (Chaput and Jones 1991a). The 10 index pools surveyed in 1990 were also surveyed in 1991 for the period June 1 to Oct. 15. Between Oct. 16 and Oct. 31, 8 index pools were surveyed including two pools on the southwest branch of the Margaree River (Fig. 1). The sampling day was divided into AM and PM periods. Each sampling period lasted 7.5 hours with the AM period commencing at 600 or sunrise depending on season and the PM period finishing at 2100 or sunset depending on season. Weekly strata were used for the time period between June 1 and Aug. 30, 1991. A total of three strata were constructed for the fall period: Aug. 31 to Sept. 22, Sept. 23 to Oct. 15, and Oct. 16 to Oct. 31. Both the AM and PM periods were sampled on the same day at least once in each stratum. The sampling effort was 5 of 7 days with one of the sample days designated for obtaining angler counts at the 32 angling pools. The Horvitz-Thompson unweighted matrices were used to estimate total catch and effort by stratum (Robson 1990). Variance estimates of effort (hours) and angling catch by size group (1SW and MSW salmon) for the summer (June 1 to Aug. 30) and fall (Aug. 31 to Oct. 15) were obtained using the Yates-Grundy variance estimator (Robson 1990). The variance estimates of the catch for the Oct. 16 to 31 sampling period were obtained by bootstrap methods (Chaput 1992) because no within day replicates were obtained. The $95 \%$ confidence intervals for the estimates were calculated using $\pm 2$ standard deviations as in the previous assessment. The creel survey field methods for Margaree River are described in Appendix A.

The estimates of total river catch were obtained using logbook reports. Creel catch at index pools was expanded to total river catch using the proportion of the logbook catch originating at index pools. The distributions of the river catch estimates for 1 SW and MSW salmon by season were generated using 6000 replications and bootstrap estimates of individual parameter uncertainty (Chaput 1992).

Volunteeer angler logbook reports which detailed the daily catch by size, release method, effort (hours) and pools fished were received and processed as in previous assessments (Claytor and Jones 1990). Logbook data were used to expand creel catch estimates to total river catch and to provide estimates of reporting rates of recaptured fish in the recreational fishery.

## Salmon Check-In Program (SCIP)

A pilot volunteer catch declaration program was initiated in 1991 for the Margaree River. Anglers were asked to report the 1 SW salmon catches to one of 5 stations where the angled fish could be sampled for biological characteristics, date of capture, location captured, etc. The declaration stations included four local business establishments and the Margaree Fish Culture Station (DFO). The program was a cooperative initiative between DFO and the Margaree Salmon Association.

## Estimation of Exploitation Rate (ER)

The exploitation rate was estimated using mark/recapture methods, similar to those used since 1988,
and the following formula:

$$
\text { ER = Tags Recaptured } / \text { Tags Available. }
$$

Two trapnets, identical in construction and installation to those of the previous assessments (Claytor and Chaput 1988), were fished within tidal waters between June 11 and Aug. 30, 1991. All salmon captured in the trapnets were marked using blue, individually numbered Carlin tags secured with a double stainless steel wire attachment directly under the dorsal fin. Tag recaptures in the angling fishery were reported in logbooks, at SCIP stations and by mail.

## Estimation of Tags Available

Losses of tagged fish due to emigration and mortality were considered minimal and were not considered further. Losses due to tag shedding by marked fish were estimated by marking all 73 MSW salmon collected for broodstock on Aug. 27 with Carlin tags prior to confinement in the holding tanks at the Margaree Fish Culture Station. The tagging method was similar to that used at the estuarine trapnets. Fish were examined for tags when spawned in late October, early November. The tag shedding rate (tags lost per day) was calculated as the ratio of the number of tags lost to the number of tags initially placed divided by the number of days since tagging (taken as 65 days in 1991). The number of tags available to anglers was estimated from the number of marked fish released multiplied by the proportion of tags retained where the proportion retained equalled (1tag shedding rate times median days to recapture) (Table 1).

## Estimation of Tags Recaptured

The tags returned voluntarily were adjusted to account for the reporting rate. The reporting rate of tag recaptures from the angling fishery was estimated for 1SW and MSW separately. The proportion of logbook tag recaptures to logbook catch reported was assumed to represent $100 \%$ reporting. The proportion of tags recaptured at index pools to estimated catch at index pools represented the partial reports. The ratio of creel catch proportions to logbook catch proportions equalled the reporting rate.

## Estimation of Returns

The estimate of returns in 1991 was obtained using the formula:

$$
\text { Returns }=\text { Angling Catch / ER (see Table 1). }
$$

The confidence around the returns estimate was quantified using simulation techniques. The returns equation was solved a total of 6000 times with the angling catch and exploitation rate allowed to vary for each replication. Variation in angling catch and exploitation rate was simulated using bootstrap techniques as described in Table 1.

## Estimation of Spawning Requirements and Spawning Escapements

The spawning requirements for the Margaree River were calculated using the formula and biological characteristics summarized in Table 2. The spawning escapement to the Margaree River was calculated using the following formula (Claytor and Jones 1990):

Sport Catch X (1-ER)
Spawners $=$
ER

For the years 1947 to 1986, DFO estimates of catch were used. For 1987 to 1991, creel survey estimates of sport catch were used. Prior to 1987, the exploitation rate for both 1 SW and MSW salmon was assumed to be uniformly distributed between 0.206 and 0.379 for both summer and fall angled fish(Claytor and Chaput 1987). The returns for 1987 to 1989 were estimated using an assumed exploitation rate for the summer (uniform distribution between 0.206 and 0.379 ) and derived exploitation rates for the fall varying from 0.11 to 0.35 for 1SW salmon and 0.09 to 0.26 for MSW salmon (Chaput and Jones 1991b). The returns and escapements in 1990 were reassessed using the simulation and bootstrapping techniques. Since 1979, summer MSW sport catch and since 1985, all MSW sport catch regardless of date of capture was added back to the spawners formula above, less $5 \%$ for hook and release mortality. The estimate of the percent of egg target met by MSW spawners exlcudes eggs collected by the DFO hatchery.

## Hatchery Releases and Returns

Releases of hatchery reared fish, by life stage, to the Margaree River were updated for 1991. The proportions of hatchery and wild salmon returning to the Margaree River were determined from angler logbooks, creel survey, SCIP reports, broodstock collections, trapnet catches, and counting fence data at Lake O'Law Brook.

## Electrofishing Surveys

A total of five electrofishing stations were sampled in July 1991. The methods were similar to those described by Chaput and Claytor (1989). Estimates of wild Altantic salmon juvenile population numbers, densities, and mean size by size group were obtained for each station. Population estimates were calculated using the Zippin method (Zippin 1956). The percent habitat saturation index (PHS) was calculated according to the method proposed by Grant and Kramer (1990):

$$
\begin{aligned}
& \text { PHS }=100 \times \sum D_{i} \times T_{i} X 1.19 \\
&\text { where } \left.D_{i} \text { is the density (per } \mathrm{m}^{2}\right) \text { of size class }{ }_{i} \\
& T_{i} \text { is the territory size }\left(\mathrm{m}^{2}\right) \text { for size class }{ }_{i} \text { predicted from the territory size- } \\
&\text { body size regression (Grant and Kramer } 1990) .
\end{aligned}
$$

The index was calculated for the 1991 stations and for previous years as an indication of present juvenile abundance relative to previous levels and potential levels.

## RESULTS

## Recreational Catches and Catch Rates

The DFO estimated catch of 1SW salmon from the Margaree River between June 1 and Oct. 31, 1991 was 246 (Table 3). MSW salmon catch estimates were not obtained by field personnel in 1991.

Preliminary license stub estimates of catch from the Margaree River for 1991 were 743 1SW salmon and 1786 MSW salmon (Table 4). The previous 5 year mean license stub catch from the Margaree River was 770 1SW salmon and 1900 MSW salmon. The angling catch and effort for the Margaree River represented $60 \%$ of the 1SW salmon catch, $50 \%$ of the MSW salmon catch and $72 \%$ of declared effort (rod-days) for SFA 18 in 1991. (Table 4).

Creel catch estimates of MSW salmon from the index pools in 1991 were down substantially from 1990 catches for both the summer and fall periods. The MSW salmon catch in 1991, up to Oct. 15, was $46 \%$ of the 1990 catch. The 1991 ISW salmon catch estimate up to Oct. 15 was $95 \%$ of the 1990 catch estimate (Table 5). The effort estimate was $94 \%$ of the 1990 value. Forks Pool was favored over all other index pools during June to October in 1990 but only for August and September in 1991 (Fig. 2). Effort was reduced substantially at the lower index pools (LTHOM, SEAL, and FORKS) in late fall in 1991 relative to previous time periods and 1990 (Fig. 2) because high water conditions rendered the pools unfishable during most of the late fall. Effort increased with the progression of the seasons in both AM and PM periods during 1990 and 1991 (Fig. 3).

The 1SW and MSW salmon catch proportions from the index pools, estimated using logbook catches versus tag recapture distributions, were similar for MSW salmon but differed for 1 SW salmon catch from the fall (Table 6). The estimated proportion of MSW salmon from index pools in 1990 was also similar between the two data sources (Table 7). The effort proportions based on angler counts were most different from either tags or logbook data. In the 1990 assessment, the tag recapture proportions were used for expanding the 1990 fall catch of 1SW and MSW salmon but proportion of effort had to be used for the summer (Chaput and Jones 1991a). A reanalysis of the 1990 data using logbooks versus tag recaptures for the fall resulted in only minor changes in estimated catch and returns for 1990 (Table 7; Chaput 1992). As a result, logbook proportions were used for expanding the index pool catches to total river catch in 1990 and 1991.

The 1991 estimated catch of 1 SW salmon, up to Oct. 15, from the Margaree River was 391, $153 \%$ of the 1990 estimated catch (Table 8). The MSW salmon catch up to Oct. 15, 1991 was 595 , about $35 \%$ of the 1990 catch (Table 8). The catch of MSW salmon was down in both the summer and fall periods in 1991 relative to 1990.

The logbook reports for 1991 (Table 9), when compared to previous years, illustrate some consistent patterns in the catch rates of 1SW salmon and MSW salmon.

|  |  |  | YEAR |  |  |
| :--- | ---: | ---: | ---: | ---: | ---: |
| Summer | 1991 | 1990 | 1989 | 1988 | 1987 |
| Effort (Rod days) |  |  |  |  |  |
| 1SW (\#/rod day) | 0.073 | 359 | 490 | 412 | 163 |
| MSW (\#/rod day) | 0.129 | 0.092 | 0.078 | 0.117 | 0.166 |
| Fall (Sept.1 - Oct. | 15) |  |  | 0.106 | 0.403 |
| Effort (Rod days) | 391 | 306 |  | 0.147 |  |
| 1SW (\#/rod day) | 0.082 | 0.092 | 0.041 | 0.111 | 0.063 |
| MSW (\#/rod day) | 0.355 | 0.127 | 0.325 | 0.682 | 0.250 |
| Fall (Oct. 16 - 31) |  |  |  |  |  |
| Effort (Rod days) | 39 |  |  |  |  |
| 1SW (\#/rod day) | 0.103 |  |  |  |  |
| MSW (\#/rod day) | 0.487 |  |  |  |  |

The logbook anglers were almost three times more successful at hooking a MSW salmon in the fall of 1991 than in 1990. Summer success in 1991 was similar to 1990 and has been relatively constant since 1987. Catch rates increased in the fall relative to the summer, and the catch rates during the season extension in 1991 were higher yet than early fall catch rates.

Logbook catch rate and creel catch rate trends do not always agree. Catch per unit effort from creel data gave a dramatically different impression of abundance for 1991 relative to 1990 than did the logbook data: the creel MSW catch per hour in 1990 was about three times greater than the 1991 catch rates for both summer
and fall. Logbook and creel catch rate trends were similar for summer and fall 1991 (Table 9): the logbook angler success rate in the fall of 1991 was three times higher than for the summer, similar to the creel data trend.

## Distribution of Tagging Effort and Recaptures

A total of 164 1SW salmon and 203 MSW salmon were marked and released from the estuarine trapnets between June 11 and Aug. 30, 1991 (Table 10). The largest portion of the catch occurred in August representing $77 \%$ of total salmon marked and released (Fig. 4). The modal length of 1 SW salmon was 52 cm whereas MSW salmon had a modal length of 75 cm (Fig. 4).

About $15 \%$ of the 1SW salmon tags and $12 \%$ of the MSW salmon tags were returned by anglers (Table 10). Of the 31 SW salmon marked and released during the broodstock seining on Aug. 27, 1991, $29 \%$ were recaptured by anglers whereas $10 \%$ of the 21 MSW salmon marked and released were subsequently recaptured (Table 10).

All the recaptures of 1SW salmon marked and released from the trapnets before July 30 (pre week 31), were reportedly caught before Aug. 19 (Table 11). The 1SW salmon marked and released in August were recaptured throughout Aug., Sept., and Oct. (Table 11). The median days to recapture for estuarine trapnet marked 1SW salmon was 19 days (Table 1).

MSW salmon marked and released before July 30 (pre week 31) were recaptured in both the summer and fall seasons, as were some of the MSW salmon marked in August (Table 11). The median days to recapture for MSW salmon marked at the trapnets was 35 days (Table 1).

## Estimation of Returns Equation Parameters

The angling catch data used in the estimation of returns for 1947 to 1991 are summarized in Table 12. The parameters which made up the returns equation in 1991 are presented in Table 1. The 1990 data were reanalysed using a similar technique although not all the parameters were analysed in the same way (Appendix B; Chaput 1992). The main differences were:

- Reporting Rate: in 1990, RR was calculated for 1 SW and MSW combined because of the small number of tag returns (3) from the logbook anglers. In 1991, RR was calculated seperately for 1SW and MSW salmon. Adjusted reporting rate means that RR values greater than 1 were set equal to 1 in the simulations.
- Tags available were calculated using tags placed, the tag loss rate and the median days to recapture for 1SW and MSW. In the 1990 assessment, Chaput and Jones (1991) had used mean days to recapture rather than median.
- ER's in 1991 were considered to be integrated values over the entire angling season for the following reasons:

1 - no marks were placed after Aug. 30, 1991,
2 - marked fish were recaptured throughout the summer and fall.
In 1990, summer ER was assumed to be between 0.206 and 0.379 . New estimates of fall ER for 1SW and MSW salmon for 1990, generated using the simulation technique, were 0.19 for 1 SW and 0.13 for MSW salmon (Table 8).

The returns in 1991, based on angling catches up to Oct. 15, were 1909 1SW salmon ( $90 \%$ C.I. 794 to 3891 ) and 3484 MSW salmon ( $90 \%$ C.I. 1853 to 5785) (Table 8, 13). The 1991 returns were $191 \%$ and $31 \%$ of 1990 returns of 1SW and MSW salmon respectively but were as high as the highest returns noted since 1984 (Table 13).

The escapements in 1991 were estimated at 1507 1SW salmon ( $90 \%$ C.I. 644 to 3116) and 3453 MSW salmon ( $90 \%$ C.I. 1836 to 5740) (Table 13). These escapements resulted in an estimated egg deposition by MSW salmon equal to $326 \%$ of target ( $90 \%$ C.I. $170 \%$ to $547 \%$ ) or $334 \%$ by both 1 SW and MSW salmon (Table 13). Potential egg depositions by MSW salmon have exceeded target egg depositions since 1985, even at the lower confidence limit (Table 13).

## Electrofishing Surveys

The densities of fry at the five sites were high in 1991, ranging from 36.2 to 230.2 fry per $100 \mathrm{~m}^{2}$ (Table 14). Parr densities were also high, ranging from 20.8 parr per $100 \mathrm{~m}^{2}$ at the Trout Brook site (Lake Ainslie tributary) to 73.0 parr per $100 \mathrm{~m}^{2}$ at one of the Forest Glen Brook sites (Table 14). Higher densities of fry ( 383 per $100 \mathrm{~m}^{2}$ ) and parr ( 88 per $100 \mathrm{~m}^{2}$ ) were recorded at Forest Glen Brook sites in 1987 (Chaput and Claytor 1989). Fry densities at the MacFarlane's Brook site were 2 to 4 times those observed between 1975 and 1978 whereas parr densities were 2 to 10 times higher (see Chaput and Claytor 1989). The fry densities at the Big Brook site are the highest ever recorded since 1964. The parr densities at the Big Brook site were similar to those of the late 1980's, about half those of the 1960's but 4 times those of the 1970's. The PHS index values for the Margaree River ranged from $13.8 \%$ to $59.7 \%$ (Fig. 5). With the exception of Trout Brook, the PHS index values suggested that density-dependent responses, such as emigration, mortality or reduced growth rates, were likely occurring in the Margaree River.

## Lake O'Law Fence

A counting fence on Lake O'Law Brook was operated from May 2 to Nov. 18 1991. Movements of Atlantic salmon by life stage are summarized below.

The estimated rearing area for Lake O'Law Brook is $97,200 \mathrm{~m}^{2}$. The egg requirements are 233,280 which would be acheived by 36 MSW salmon. The fence was located about 1.5 km upstream of the confluence with the Margaree River. Counts through the fence were 2.1 times the required number.

## Hatchery Contributions

Releases of hatchery progeny to the Margaree River by life stage are summarized in Table 15. The proportions of hatchery and wild 1 SW and MSW salmon by collection method are summarized in Table 16. The trapnets provide the best indication of the proportion of wild salmon in the runs because of the larger sample size and the estuarine location from which samples were obtained. Prior to Aug. 31, the 1SW salmon run was $81 \%$ wild origin and the MSW salmon run was $91 \%$ wild origin (Table 16). The high proportion of hatchery origin fish in the broodstock samples and the SCIP/Creel samples relates to the larger number of samples which were collected from Hatchery Pool, the pool situated next to the Margaree Fish Culture Station.

## Marine Exploitation of the Margaree River Atlantic Salmon

The Margaree River Atlantic salmon kelts, as well as returning previous spawners, are regularly intercepted in the Newfoundland and Quebec north shore commercial fisheries (Table 17). One salmon, from the 1989 spawning migration, was recaptured in the Greenland commercial fishery in 1990 (Table 17).

## DISCUSSION

The angling catch, returns, and escapement estimates, obtained using simulation techniques, permitted the inclusion of uncertainty in several of the estimation parameters. The results were simpler to interpret and provided a clearer picture of the overall confidence around the returns and escapements estimates.

The return of MSW Atlantic salmon to the Margaree River in 1991 was down substantially from the record return of 1990. The spawning escapement in 1991 was three times the target spawning requirement. The similarly high escapement to the Lake O'Law fence, two times the requirement for that size of tributary, provided supporting evidence for the estimated escapement to the entire river. The return of 1SW salmon in 1991 was strong and may provide some positive forecast of MSW salmon returns in 1992.

The use of angling catch and exploitation rate to estimate returns is, unfortunately, far from perfect. The exploitation rate should be calculated every year because river conditions have a very large impact on exploitation rate. The integrated ER calculated in 1991 oversimplifies the pattern of exploitation. The estimated ER is correct for fish entering the river prior to September but it is likely too high for those fish which entered after. In that case, the returns are underestimated.

In previous assessments, the angling catches from the summer and fall were treated as two distinct components representing the respective sizes of the runs. The mark/recapture data from 1991 indicate that this was not the case. Some of the fall recreational catch consisted of fish which had been marked and released in the summer. The exploitation rates derived in 1988 to 1990 for fall angled fish actually correspond to exploitation rates for fish entering and angled in the fall. This overestimated the fall returns while underestimating the summer returns. The overestimation was probably not excessive since the large portion of the fall catch was expected to be fall fish. A marking study which covers the entire season would provide some indication of the relative proportions of summer and fall run fish in the catches. An estimate of population size,
independent of angling recaptures, would provide the best indicator of stock status.
The densities of Atlantic salmon juveniles in the Margaree River were high. The PHS index values were in the range that predicted the occurence of density-dependent effects in the tributaries. The PHS index is a measure of spatial saturation only and ignores other factors such as quality of habitat, productivity, and predation (Grant and Kramer 1990). These authors suggested that the PHS index could be used as a rough guide for setting maximum stocking densities. Stocking fish into a stream where the PHS is greater than 27 would likely cause a density-dependent response in either the resident or stocked population (Grant and Kramer 1990). On that basis, hatchery-reared juveniles should not be stocked in the tributaries of the Margaree River which were surveyed in 1991.

The abundance of juveniles has increased dramatically from the low levels noted in the 1970's and have either equalled or surpassed the juvenile densities noted in the late 50 's and early 60 's. It is interesting to note that the PHS index for the Forest Glen Brook sites has not varied over time and has not shown the dramatic increase in 1991 relative to previous years as was seen at the Big Brook site. The Forest Glen Brook appears to have received adequate spawning throughout the time period studied whereas lesser tributaries such as Big Brook have responded to the increased adult escapement between 1986 and 1991.

The Atlantic salmon resource of the Margaree River has increased in abundance since 1985 to the point where surpluses of fish to presently designated spawning requirements are occurring every year. A forecast for 1992 and beyond is not available but given the escapements that have been estimated since 1985, returns of MSW salmon will likely exceed spawning requirements in 1992 and beyond if factors such as habitat degradation are minimized.

Figure 1. Margaree River, NS, showing index pool locations for 1991 creel survey, trapnet location, and electrofishing stations (*---).

Figure 2. Angiling effort (mins) per visit at the Index pools by month for 1990 and 1991. One visit is equivalent to 60 mins of observation time.

Figure 3. Comparison of AM and PM stratum angling effort by month for Margaree River, 1990 and 1991.

Figure 4. Length frequency distribution and timing of catches of Atlantic salmon at the trapnets on the Margaree River, 1991.

Figure 5. Grant and Kramer (1990) Percent Habitat Saturation index for Atlantic salmon juveniles from the Margaree River, 1976 to 1991. Symbols are as follows: $\mathrm{a}=$ Big Brook sites, $\mathrm{b}=$ MacFarlane's Brook site, $\mathrm{c}=$ Trout Brook site, and all other symbols are Forest Glen Brook sites. Dotted line denotes the 27\% PHS value delimiting the inflection point in the logistic regression of density dependent effects on PHS (Grant and Kramer 1990).

APPENDIX A. Instructions for conducting the creel survey of the Margaree River Atlantic salmon recreational fishery, 1991.

The creel survey is designed as a bus route where the clerk travels along a predetermined route with prescribed stops of fixed duration at several points on the route. The direction of travel for Margaree River is in an upstream direction. There are ten (10) designated stops of fixed duration along the route:

| Lower Thompkins Pool (LTHOM) | -60 minutes |
| :--- | :--- |
| Seal Pool (SEAL) | -60 |
| Forks Pool (FORKS) | -120 |
| Doyles Bridge Pool (DOYLES) | -60 |
| Little McDaniel Pool (LMCD) | -60 |
| Cranton Bridge Pool (CRAN) | -60 |
| Hart Pool (HART) | -60 |
| Hatchery Pool (HATC) | -60 |
| Ross Bridge Pool (ROSS) | -60 |
| Tent Pool (TENT) | -60 |

After Tent Pool, Lower Thompkins Pool should be sampled, etc.
The day is divided into two sampling periods (AM and PM) starting at 600 and 1330 hours and lasting 7.5 hours each. The actual start time may vary somewhat on the schedule and these start times should be respected. The clerk starts at the pool selected for that day, and stays at that pool for the indicated period of time. The actual observation of angling activity should begin at the pool exactly at the time indicated, not get out of vehicle at that time. After the required observation time for the first pool is completed, the clerk walks back to the vehicle and moves to the next pool in the sequence, in an upstream direction. The actual creel period begins when the clerk arrives at the pool where angling can be directly observed. The creel period for that pool corresponds to the creel durations indicated above.

The clerk moves through the sequence of pools until the sampling period is completed (up to 1330 for AM creels and 2100 for $P M$ creels). The last pool sampled may only be for 15 minutes but even this period of observation should be completed.

Data to be collected at each pool:
On arrival, the clerk counts the number of anglers actually fishing and records this number with the start time on the form. As changes occur in the number of anglers, the clerk records with the corresponding change (for example, +1 or -2 designating one more angler or 2 less anglers fishing) and the time the change occurred. At the same time, fish which are hooked, lost, kept, released, etc. are recorded. The following designations should be used:

LOST - fish is hooked but unsuccessfully landed. This category includes fish which are on for 5 seconds and fish which are on for 15 minutes if the intent of the angler was to land the fish but fish broke away. This type may have a size category, grilse or MSW but more often does not.

GRILSE - KEPT - grilse which is landed and kept by the angler. Attempts should be made to look at the fish to determine if it is a wild or adipose clipped fish, if it has an external tag or if a tagging mark is present, to get length and a scale sample if possible.

GRILSE - REMOVED HOOK - grilse which is released from the hand by the angler. Should note if it is wild or adipose clipped, if external tag is present or if tagging mark is present. APPENDIX A (Cont'd).

GRILSE - CUT LINE - grilse which is released by snapping the line, not handled on shore. Wild or probably be unknown. Tag or untagged may also be unknown.

MSW - REMOVED HOOK - Large salmon which is released by hand. Attempts should be made to determine if the fish is wild or hatchery origin, if it has an external tag or if tagging mark is present. No scales should be collected.

MSW - CUT LINE - Large salmon which is intentionally released by cutting or snapping the line. Wild or hatchery origin may not be evident. Presence of tag may also be unknown.

All the above activities should be noted if they occur.

## APPENDIX A (cont'd).

At the end of the creel period for the pool, the number of active anglers and the time the observation period ends are recorded.

Anglers which leave the pool while the clerk is on site should be interviewed if possible. The following data should be obtained for each angler:

- time started fishing at given pool
- time finished fishing at given pool
- numbers of fish by size category lost, hooked and released, kept.
- fish which are kept should be sampled for length, scales and sex if fish is or was cleaned. Look for external tags, adipose fin clips, tagging scars below the dorsal fin, etc.
- for sampled fish, obtain angler name and address if the individual would like information of the kept fish and angling success in general on the river, to be sent at the end of the year.

For the Oct. 16 to Oct. 31 creel, the following pools will be monitored:

| Lower Thompkins Pool (LTHOM) | -60 minutes |
| :--- | :--- |
| Seal Pool (SEAL) | -60 |
| John Archie (SWARCH) | -30 |
| Forks Pool (FORKS) | -90 |
| Gerard Chiasson (SWGCH) | -30 |
| Doyles Bridge Pool (DOYLES) | -60 |
| Little McDaniel Pool (LMCD) | -60 |
| Cranton Bridge Pool (CRAN) | -60 |

## RIVER COUNTS

Since only 10 pools are surveyed during the present creel and the Margaree River has in excess of 60 pools (historically), the effort on the entire river must be determined in order to estimate catch from the entire river. Counts of anglers are obtained at 32 pools on the.river on specific days. The clerk starts at the designated pool and working in an upstream direction, counts the number of anglers at each pool and the time of observation. River counts will be obtained in AM and PM periods. No interviews are conducted but opportunistic samples of fish length, scales, tag marks, adipose clipped, etc. may be obtained if the opportunity presents itself. The counts are recorded on the special forms.

APPENDIX B. Formulation for the estimation of the returns of Atlantic salmon to the Margaree River, 1990 . Boldtype indicates parameters which changed value for every repetition:

RETURNS (1SW; MSW) =

## CATCH (1SW; MSW)

EXPLOITATION RATE (1SW; MSW)
CATCH (1SW; MSW) = Catch Summer + Catch Fall
Est. Creel Catch from Index Pools (CCI)

Proportion of Catch from Inder Pools (PCI)
CCI ---> 1SW summer assumed distribution $N(135,2601)$
1SW fall assumed distribution $N(33,441)$
MSW summer assumed distribution N(192, 3844)
MSW fall assumed distribution $N(533,24180)$
PCI ---> variability simulated using bootstrapping.
Using logbooks:
summer $N=20$ 1SW prop. $27 / 40=0.68$
MSW prop. $29 / 55=0.53$
fall $N=22 \quad 1 S W$ prop. $\quad 20 / 32=0.63$
MSW prop. $\quad 20 / 50=0.40$
Using tag returns from angling fishery:
fall $\quad$ 1SW prop. $\quad 7 / 13=0.54$

MSW prop. $\quad 6 / 16=0.38$

EXPLOITATION RATE (1SW; MSW) = Tags Recaptured / Tags Available
Estimated for fall only.
Assumed for summer, uniform distribution between 0.206 and 0.379 for both 1 SW and MSW.

Tags Returned Voluntarily (1SW; MSW)

Reporting Rate (RR)
Bootstrap estimates of $R R$ for 1990 estimated from:
Tag Recaptures from Index Pools (1SW + MSW)
Creel Catch Estimate at Index Pools (1SW + MSW)
$\mathbf{R R}=$
Tag Recaptures by Logbook Anglers ( $1 \mathrm{SW}+\mathrm{MSW}$ )
---------------------------------------------
Logbook Catch (1SW + MSW)
Nonbootstrap value $=(13 / 566) /(3 / 82)=0.62$
Note: Logbook catch of 82 is updated value from that reported by Chaput and Jones (1991).

Tags Available (1SW; MSW) = Tags Placed X Proportion Retained(PR)
PR $=1$ - (Tag Loss Rate) X Median Days to Recapture
In 1990, tag retention experiment was performed. Of 18 fish marked and held for 21 days, 5 tags had been shed. Tag loss rate (per day) $=0.013$.

Recapture data is bootstrapped to obtain median days to recapture.

1SW Recaptures: $N=13$, Range 1 to 25 days, Median $=4$ days
MSW Recaptures: $N=17$, Range 0 to 20 days, Median $=6$ days

## APPENDIX B (cont'd).

## Note: In the 1990 assessment, mean days to recapture were used (Chaput and Jones 1991) <br> 1SW: Mean $=10.9$ days MSW: Mean $=7.7$ days

SUMMARY EQUATION

RETURNS (1SW; MSW) $=\quad$| CCI (Summer) | CCI (Fall) X Tags Placed X PR X RR |
| :--- | :--- |
| ER (Summer) $X$ PCI (Summer) | PCI (Fall) X Tags Returned Voluntarily |

Solve RETURNS a large number of times to generate the distribution from which the Confidence Limits can be determined.
