¹This series documents the scientific basis for fisheries management advice in Atlantic Canada. As such, it addresses the issues of the day in the time frames required and the Research Documents it contains are not intended as definitive statements on the subjects addressed but rather as progress reports on ongoing investigations.

Research Documents are produced in the official language in which they are provided to the Secretariat by the author.

¹Cette série documente les bases scientifiques des conseils de gestion des pêches sur la côte atlantique du Canada. Comme telle, elle couvre les problèmes actuels selon les échéanciers voulus et les Documents de recherche qu'elle contient ne doivent pas être considérés comme des énoncés finals sur les sujets traités mais plutôt comme des rapports d'étape sur les études en cours.

Les Documents de recherche sont publiés dans la langue officielle utilisée par les auteurs dans le manuscrit envoyé au secrétariat.

Abstract

Total landings for cod in Div.5Zj,m in 1991 were 20000 t , about equal to that of last year , and above the long term average of 17000 t. The 1987 yearclass (age 4) was dominant (37% in numbers). Size at age 1 for Canadian samples shows an increase over long term averages. The most recent Canadian and USA surveys show a decline in mean catch per tow, and the USA fall survey is anomalously low. A shift in distribution or in catchability of cod in this area may have occurred. Vessel and door conversion factors were applied to USA surveys and most of the decrease in the population estimates was attributed to these factors. Results of an ADAPT formulation were not significant and estimated unrealistically high exploitation in 1991. Analysis of catch and effort information suggests that exploitation rates have increased since 1989 but were similar in 1990 and 1991. Therefore population numbers for 1992 were derived using a 1991 F of 0.7 and projections completed at twice $F_{0.1} = 0.4$ for 1992 and 1993. Results of this projection indicate a catch biomass of less than 15000 t for 1992 and 1993. Actual catches in 1992 are expected to be similar to 1991, since the 1992 management plan has already been implemented. This implies a 1992 F of about 0.8, nearly twice F_{max} . Joint action by the USA and Canada will be required if conservation measures are to be effective.

Résumé

Les débarquements totaux de morue provenant des divisions 5Zj,m se sont établis à 20 000 t en 1991, ce qui équivaut à peu près à ceux de l'an dernier et est supérieur à la moyenne à long terme (17 000 t). La classe d'âge de 1987 (âge 4) dominait dans les prises (37 % du nombre). Dans les échantillons canadiens, la taille à l'âge 1 est en hausse par rapport aux moyennes à long terme. Les campagnes d'évaluation canadiennes et américaines les plus récentes révèlent une diminution des prises moyennes par trait et les résultats de la campagne d'évaluation américaine d'automne sont anormalement bas. Cela peut être dû à un changement dans la distribution ou dans le potentiel de capture de la morue dans la région considérée. La majeure partie de la baisse constatée dans les estimations de population obtenues lors de la campagne d'évaluation américaine a été imputée aux facteurs de conversion appliqués aux bateaux et aux panneaux. Les résultats d'un calcul utilisant la méthode ADAPT n'étaient pas probants et aboutissaient à une estimation irréaliste de forts taux d'exploitation en 1991. L'analyse des renseignements sur les prises et l'effort donne à penser que les taux d'exploitation ont augmenté depuis 1989, mais qu'ils étaient comparables en 1990 et en 1991. Les estimations de population pour 1992 ont donc été calculées à partie d'une valeur F de 0,7 en 1991 et les projections ont été établies à deux fois $F_{0.1} = 0,4$ pour 1992 et 1993. D'après ces projections, la prise pour 1992 et 1993 serait inférieure à 15 000 t. On s'attend à ce que les prises réelles de 1992 soient comparables à celles de 1991, le plan de gestion de 1992 ayant déjà été mis en oeuvre. Cela situe F à environ 0,8 en 1992, soit près de deux fois F_{max} . Une intervention commune du Canada et des États-Unis serait requise pour que les mesures de conservation soient efficaces.

Introduction

The present report incorporates commercial catch data and research survey results to estimate stock status of cod for the 1978-91 time period in the two unit areas 5Zj and 5Zm (Figure 1). Definition of this management unit is based on analysis of tagging results as well as commercial and survey catch distribution and more recent tagging studies (Hunt, 1990).

Cod are taken by both Canada and the USA in unit areas 5Zj and 5Zm and all data relating to USA catches and research vessel surveys were provided by the National Marine Fisheries Service (NMFS) at the Woods Hole, Mass., Laboratory.

Trends in Reported Landings

Catches by the USA in unit areas 5Zj and 5Zm are thought to be or mis-reported with extensive discarding prior to 1978 (Serchuk and Wood, 1981) and estimates of population status prior to this time are suspect. Catch statistics since 1977, when foreign fleets were excluded from the 200 mile economic zones of Canada and the USA, are thought to be more reliable. As well, spatial distribution of foreign fleet catches in Subdiv. 5Ze are unknown. There have been no reported landings by foreign fleets since 1978.

Fishery by Country and Gear

Canadian catches of cod are taken on the "Northeast Peak" of Georges Bank primarily between April and November. Landings have been dominated by otter trawlers, except in 1984 and 1989 (Table 1, Fig. 2). The below average 1989 catch by otter trawlers reflects early closure of the fishery when the combined quota for Div. 4X+5 was exceeded.

In 1990, a 6000 t increase in Canadian landings was the result of a return to historic catches by the OTB fleet and an overall catch of 14310 t, the second highest in the time series. Canadian landings in 1991 where 13455t. USA landings in 1991 where 6549 t, about the average for recent years. Management of the Canadian fishery in 1990 and 1991 was by individual and equal boat quotas of 280000 lb with by catch restrictions.

Catches by Canada and the USA in unit areas 5Zj and 5Zm for 1978-91 are summarized in Table 2 and in Figure 3. Catches peaked at 26000 t in 1982, averaged to about 15000 t between 1983-87 and increased to 20000 t in 1988. Since 1985, Canada has taken about 65% of the total catch. The reduction in 1989 to 14000 t was a result of decreased mobile gear catch by both Canada and the USA.

Age Composition of the Commercial Catch

Sampling Intensity

Sampling coverage of the Canadian fishery prior to 1985 averaged about one sample per 1000t landed. Prior to 1978, sampling levels for Canadian catches were very low and it is unlikely that reliable estimates of removals at age could be obtained. Since 1985 sampling has increased and in 1991, 45 samples were collected. Numbers of fish aged and measured for USA and Canadian

samples for 1978-91 are shown in Table 3. Combinations of length and age samples used to estimate the 1991 catch at age for Canada and the USA are shown in Table 4a,b.

Age Composition

For the length-weight relationship, values for a and b were derived from Canadian commercial sampling data. With round weight in kilograms and length in centimetres these values were weight (kg)=0.0000163 x length^{2.9048} and they were used for both Canadian and USA sampling data.

Canadian samples were used to obtain statistics by age. Initial aggregation was by gear type and quarter. The bias introduced by applying otter trawl length frequencies to partition longline catches may be significant in years (1978-80) lacking samples for this gear.

Catch at age in the USA fishery for 1991 was estimated from USA samples of 5Zj and 5Zm catches for each year. Annual samples by market category and month (or less frequent intervals if samples were not available) were combined to provide estimates of catch at age by market category.

Comparison of percent catch at length for Canadian and USA otter trawlers in the second quarter of 1991 is shown in Figure 4 and indicates some difference in the two fisheries. In general, the USA fleet appears to catch a higher proportion of larger fish.

Estimated total removals at age are given in Table 5 by country.

Percent catch at age for total landings of 5Zj,m cod are shown in Table 5 and in Figure 5 and the 1987 yearclass was dominant (37%) in 1991.

Neilson et al (1991) conclude that using the sum of Canadian and USA derived catch at age gives the best estimate of total removals by the 5Zj,m fishery. This is consistent with the approach taken by USA biologists in their assessment of Georges Bank cod (Anon, 1992)

Mean length and weight at age for Canadian samples are given in Table 7. The plus age group was set to 115 cm and 15 kg, the approximate mean for ages 10-15. There appears to be no trend in size or weight at age over the 12 year time series, although mean weight at age in 1990 and 1991 appear to be above the long term average. Mean weights at ages 2 and 3 in 1990 and 1991 are above the average and will have a substantial positive impact on estimated population biomass.

Stock Abundance Trends

Research Surveys

Depth-stratified, random bottom trawl surveys have been conducted by NMFS in the autumn since 1963 and a spring survey was added in 1968. A summer survey was conducted from 1977 to 1981. Surveys in Subdivision 5Ze were completed by Canada in March 1986-92. The USA spring survey used the larger "Yankee 41" trawl from 1973-81. However, the USA has not adjusted its surveys for this factor, based on the conclusions of an intervention study suggesting minimal

impact on catches of haddock and, presumably cod (Anon, 1992). New trawl doors have been used for both spring and autumn surveys since 1985. Analysis of a study to develop conversion factors indicates the new trawl doors are more effective by a factor of 1.56 for cod (Anon, 1992). Therefore USA survey estimates for 1977-84 were adjusted upward by this factor. The USA has also reported a difference in the fishing power of the vessels used to conduct their bottom trawl surveys (Anon, 1992). The Albatross was determined to be less efficient than the Delaware II by a factor of 0.79 (Anon, 1992) and therefore all Delaware surveys were adjusted by this factor. These conversions results in standardization of indices to the equivalent of the Albatross IV.

Hunt (1990) describes the approach used to estimate mean catch per tow specific to the 5Zj,m area for Canadian and USA surveys. The technique required selecting only sets within the 5Zj,m boundary and using strata areas also within the 5Zj,m boundary.

Results of analysis for each of the surveys are given in Table 8. The 1982 USA spring survey is influenced by one tow of 1000 fish and the resultant high catch rate has a high standard error. This tow has been excluded by USA researchers in their analyses (Anon, 1992). Examination of tows in the 1982 survey indicates above average catches in several sets and strata and therefore all tows were included in the present study.

Total catch per tow has been variable for each of the surveys but has been relatively stable in recent years. However, the 1991 Canadian survey shows a marked decline from the high 1990 value and the decline continues in 1992. The 1991 USA fall survey catch per tow is the lowest on record. Catch per tow is strongly influenced by progression of year-classes over time and in particular the 1983 and 1985 yearclasses.

Anecdotal reports from Canadian fishermen suggest that cod were found in deeper water during the 1991 season and if this trend persisted into the fall of 1991 then catchability for cod during the USA fall survey may have decreased. The USA survey includes strata in deeper water outside the 5Zj,m area. To determine if changes in the distribution had occurred, the USA fall surveys were examined to estimate relative abundance between the 5Zj,m area and the adjacent deeper water area. In 1991, the index for the management area declined abruptly but there was no increase in the adjacent area. This does not suggest a change in distribution between these areas.

YEAR	Strata to 5Zj,m	Management area 5Zj,m
1984	2.12	6.74
1985	0.84	4.75
1986	0.42	6.09
1987	0.42	2.45
1988	0.21	4.44
1989	0.50	5.68
1990	0.66	4.01
1991	0.41	0.72

The fall survey is assumed to be a post-fishery index and spring surveys are assumed to be a pre-fishery index. Therefore the fall survey is lagged by one year for comparison of indices (ie.

pre-fishery index. Therefore the fall survey is lagged by one year for comparison of indices (ie. fall 1977 age one vs spring 1978 age two). In general, all three surveys appear to track yearclass strength and provide a consistent index. The 1987 yearclass, which will be a substantial factor in the 1990-93 fishery, appears to be above average in the Canadian and USA spring surveys in 1989-91. The 1990 yearclass also appears to be above average in the Canadian 1992 survey but the 1991 yearclass at age 1 is the minimum observed.

Commercial Catch Rates

Canadian C/E for the mobile gear fleet in 1989 was not considered to be a reliable index because of the premature closure of the fishery and an updated C/E series was not possible. USA C/E was not yet available for 1988-91. Therefore commercial OTB C/E was not included in the analysis.

A longline CPUE series, using Canadian vessels of TC 2 and 3 was examined by Hunt et al (1991). However, there were several discrepancies between the series which convinced them that the CPUE series, as currently developed, is not useful for inclusion in the ADAPT formulation. For example, the CPUE declined from the highest to the lowest observed value between 1989 and 1990 when other indications were that biomass levels were currently very high. Pending further analysis of this C/E series, they concluded that it would be inappropriate to include it in the ADAPT formulation.

Estimation of Stock Size

The ADAPT formulation used to estimate used population parameters for 1978-91 included all three survey indices.

Year-class estimates $N_i, 1991 \quad i=2,9$

Calibration coefficients for each of the three surveys, where

- $K_i \quad i=1,4$ USA spring survey
- $K_i \quad i=0,3$ USA autumn survey
- $K_i \quad i=1,4$ Canadian spring survey

Assumed catchability for ages greater than age 4 (age 3 autumn) equal the oldest estimated for each survey. The following structure was imposed in ADAPT model:

- error in catch assumed negligible
- F on oldest age group set to weighted F for ages 3-8
- no intercept term fitted
- natural mortality set to 0.2
- logarithmic transform for indices

Input for the model consisted of:

- $C_{i,t} \quad i=1,9; t=1978-91$

- RV_{i,t} i=1,9; t=1978-91 USA spring survey
- RV_{i,t} i=0,8; t=1977-91 USA fall survey
- RV_{i,t} i=1,9; t=1986-92 Canadian spring survey

and the objective function required minimization of:

$$\begin{aligned} & \{\text{obs}(\ln RV_{1i,t}) - \text{pred}(\ln RV_{1i,t})\}^2 \\ & + \{\text{obs}(\ln RV_{2i,t}) - \text{pred}(\ln RV_{2i,t})\}^2 \\ & + \{\text{obs}(\ln RV_{3i,t}) - \text{pred}(\ln RV_{3i,t})\}^2 \end{aligned}$$

and a total of 20 parameters were estimated. Residuals for survey indices with zero catch at age (predominantly the USA fall survey) were excluded from the overall sum of residuals.

Coefficients of variation were very high for all three surveys. Residuals for both USA survey indices were balanced in most cases but some year effect was evident for several years and was very strong in the 1991 USA surveys (Table 9). Calibration coefficients and population estimates were not statistically significant from the above run (Table 10).

Assessment Results

Population estimates from the above ADAPT formulation are given in Table 11 and indicate that the 1985 year-class is the largest observed with about 22 million fish at age 1. The 1980, 1983 and 1987 are also estimated to be well above the 1978-89 average abundance. The 1989 year-class appears to be average in abundance at age 1. For ages 3+ abundance has decreased from a high of 16 million in 1978 to a low of about 4 million in 1991. The 3+ biomass in 1991 is less than 19000 t and at its lowest level in the 14 year average time series. Fishing mortality also shows a dramatic increase in 1991 to 1.15. Population biomass, abundance, fishing mortality for ages 3+ are given in Figures 6-8.

However, as noted above all parameter estimates are not statistically significant and do not reflect the actual abundance of the stock. The impact of conversion factors for the USA surveys and their combined effect of reducing the 1984-91 indices account for the apparent decline in abundance from that estimated in the 1991 assessment of this stock. The additional impact of the anomalously low estimate for the 1991 fall USA survey further reduces the estimate of abundance for 1991.

To assess the impact of survey conversion factors and the anomalously low USA fall 1991 survey results, Adapt formulations were examined without survey conversions and without the 1991 fall survey. Results for 1992 estimates are shown below:

	Without conversion		With conversion	
	Without 1991	With 1991	Without 1991	With 1991
1992 3+				
Biomass	40492	32067	23754	18620
Numbers (000's)	9419	7243	5811	4428
F	0.59	0.78	0.90	1.15

The impact of survey conversions accounts for most of the reduction in biomass.

Comparison of survey indices for ages 1-9 with estimated population numbers for 1978-92 is shown in Figure 8. In general the surveys track population abundance and all three surveys indicate a decline since 1990.

Catch and effort in the USA fishery are assumed to have been relatively stable in recent years. However, effort by mobile gear in the Canadian fishery is known to have increased since 1989 with the introduction of boat quotas in 1990 and 1991. Effort by Canadian fixed gear components has also increased in the last number of years. An analysis of Canadian landing statistics for days fished, as a measure of effort, is shown below (OTB= mobile gear, LL=longline, GN= gillnet):

Year	OTB	LL	GN
88	1006	355	92
89	554	860	203
90	3267	760	185
91	2532	678	272

These data suggest that the effort in 1990 and 1991 was higher than in 1988-89 and that effort in 1991 was similar to that in 1990 and not close to twice the 1990 value as indicated from the Adapt results.

Prognosis

Results of ADAPT using survey conversions and the 1991 USA fall survey are not significant and are inconsistent with other indicators of exploitation rates. However, the downward trend in abundance in recent years is probably correct as well as the relative age-specific exploitation rates. Measures of effort for 1990 and 1991 suggest that exploitation was similar for both years. Therefore, the 1992 population was estimated by prorating the 1991 F's from ADAPT (Table 12a) by the ratio of 0.7 to 1.15 and the resultant F's used with the 1991 catch to estimate a 1991 population. The projection was run for 1991-93 with fishing mortality set to twice $F_{0.1}=0.4$ in 1992 and 1993, with mean weights at age, average partial recruitment and the geometric mean for recruitment at age one. Input for the projection is shown below:

Age	January 1, 1992 Population (000's)	Average Weight (kg)	Partial Recruitment
1	8360	0.696	0.004
2	6835	1.391	0.320
3	3494	2.249	1.000
4	1945	3.579	1.000
5	819	5.012	1.000
6	550	6.448	1.000
7	1166	8.333	1.000
8	162	10.340	1.000
9	123	10.948	1.000
10+	18	15.000	1.000

Results of the projection are as follows:

	1992	1993
Biomass 3+	26673 t	28046
Numbers (000's)	23470	24649
F 3+	0.4	0.4
Catch t	11715	12264

and indicate a catch biomass of less than 15000 t for 1992 and 1993 at F_{max} . Actual catches in 1992 are expected to be similar to those of 1991 since the 1992 management plan has already been implemented. If 1992 catches are 20000 t it would imply a 1992 F of 0.8 or more than twice F_{max} . Yield and population biomass under alternative harvesting strategies are shown in Figure 10 for 1992 and in Figure 11 for 1993 assuming a 1992 catch of 20000 t. Ages 1-3 are projected to account for about 30% of the 1992 catch biomass. However, preliminary results of length frequency sampling for 1992 OTB catches indicate that the 1990 yearclass at age two accounts for over 50% of the catch in numbers (Figure 12).

Joint action by the USA and Canada will be required if conservation measures are to be effective and of benefit to Canada. Lowering Canadian catches may not be effective unless the USA respond with similar actions. The USA could take a substantial part of the total projected catch which could negate conservation measures adopted unilaterally by Canada.

Acknowledgements

The authors wish to thank Dr. Ed. Trippel and Mr. Stratis Gavaris for constructive reviews of an earlier version of the manuscript. Also the many people at the NMFS Woods Hole Laboratory who provided USA catch and sampling data and USA survey data, and Dr. Frederic Serchuk for his comments on the analysis.
