CAFSAC Research Document 92/51

Catches of 4T-Vn (Jan.-Apr.) cod in the 4Vs winter fishery, 1980-1992.
J. Mark Hanson and Gloria A. Nielsen

Marine and Anadromous Fish Division, Gulf Fisheries Centre, P.O. Box 5030, Moncton, N.B. E1C 9B6

1 This series documents the scientific basis for fisheries management advice in Atlantic Canada. As such, it addresses the issues of the day in the time frame required and the Research Document it contains are not intended as definitive statements on the subjects but rather as progress reports on ongoing investigations.

Research Documents are produced in the official language in which they are provided to the Secretariat by the authors.

1 Cette série documente les bases scientifiques des conseils de gestion des pêches sur la côte atlantique du Canada. Comme telle, elle couvre les problèmes actuels selon les échéanciers voulus et les documents de recherche qu'elle contient ne doivent pas être considérés comme des énoncés finals sur les sujets traités mais plutôt comme des rapports d'étape sur les études en cours.

Les documents de recherche sont publiés dans la langue officielle utilisée par les auteurs dans la manuscrit envoyé au secrétariat.

## SUMMARY

The occurrence of significant numbers of $4 \mathrm{~T}-\mathrm{Vn}$ (Jan.Apr.) cod in the 4 Vs winter fishery was first reported during the 1990 assessment of the 4VsW cod stock. Based on visual separation of the length-at-age distributions, $7,656 \mathrm{t}$ of the January-April catches in 4 Vs were attributed to the $4 \mathrm{~T}-\mathrm{Vn}$ (Jan. - Apr.) cod stock. Environmental conditions during the 1991 winter fishery in 4 Vn and 4 Vs were very similar to those observed during 1990 and an analytical technique was sought to estimate possible landings of $4 \mathrm{~T}-\mathrm{Vn}$ cod in the 4 Vs winter fishery. The cod in 4 VsW and $4 \mathrm{~T}-\mathrm{Vn}$ (Jan. - Apr.) grow at significantly different rates; $4 \mathrm{~T}-\mathrm{Vn}$ (Jan.Apr.) cod are much smaller at age than 4 VsW cod. An analytical method that uses length-at-age distributions for the two stocks when separate as templates to partition the quantities of the two stocks from mixed catches was evaluated. The method performed very well on an age-by-age basis when tested with a synthesized data set consisting of known mixtures of the two stocks. However; usage of the method to partition stocks from a mixed stock fishery requires accurate length-at-age data for the two templates representing the pure stocks and for the mixed fishery during the year in question. Catches in $4 V s$ were partitioned into subareas 4 Vsb and 4 Vsc to determine during which years significant catches of 4 T Vn (Jan. - Apr.) cod might occur. Catches in 4Vsb during the 4Vs winter fishery have only exceeded 3,000 t in 1982 and 1986 to 1992 ( 10,000 t in 1991). A comparison of lengths-at-age in $4 \mathrm{Vn}, 4 \mathrm{Vsb}$, and 4 Vsc suggested that average sizes at age in 4 Vsb resembled those of $4 \mathrm{~T}-\mathrm{Vn}$ cod more than 4 VsW cod in recent years. Sufficient data were available to calculate catches of $4 \mathrm{~T}-\mathrm{Vn}$ (Jan. -Apr.) cod in the 4 Vs winter fishery between 1980 and 1991. Where possible, catches were analyzed separately for the winter fisheries in 4 Vsb and 4 Vsc ( 1986 and 1988 to 1992). Estimated catches of $4 \mathrm{~T}-\mathrm{Vn}$ (Jan. - Apr.) cod in 4 Vsc ranged between 0 and 730 t during this period compared to 2,300 to $6,300 \mathrm{t}$ in 4 Vsb . The estimated catch of $4 \mathrm{~T}-\mathrm{Vn}$ (J.-A.) cod during the winter 1992 fishery in 4 Vs was $4,170 \mathrm{t}$. Estimated catches of $4 \mathrm{~T}-\mathrm{Vn}$ (Jan. - Apr.) cod in the 4 Vsb winter fishery represented and average of $55 \%$ of the total 4Vsb January to April landings during 1982, 1986 and 1988 to 1992. There currently is no allocation for catches of $4 \mathrm{~T}-\mathrm{Vn}$ (Jan. Apr.) cod in 4Vsb under the current management plan. The management plan should be modified to account for these catches.

## RÉSUMÉ

La présence de quantités importantes de morue de $4 \mathrm{~T}-\mathrm{Vn}$ (janvier à avril) dans les prises hivernales réalisées dans 4 Vs , a été déclarée pour la première fois au cours de l'évaluation du stock de morue de 4VsW en 1990. Selon la séparation visuelle des différentes tailles de morue par classe d'âge, 7656 t des prises de la pêche de janvier à avril dans $4 V$ s ont été attribuées au stock de la morue de $4 T-V n(J-A)$. Les conditions écologiques qui ont prévalu au cours de la pêche hivernale de 1991 dans 4 Vn et 4 Vs étaient très semblables à celles observées en 1990, et nous avons cherché une technique d'analyse qui nous permettrait d'estimer les débarquements possibles de morue de $4 \mathrm{~T}-\mathrm{Vn}$ dans les prises de la pêche hivernale de 4 Vs . La morue de 4 VsW et celle de $4 \mathrm{~T}-\mathrm{Vn}(\mathrm{J}-\mathrm{A})$ croissent à des rythmes très différents. La morue de $4 \mathrm{~T}-\mathrm{Vn}(\mathrm{J}-\mathrm{A})$ est beaucoup plus petite que
celle de $4 V s W$ du mème âge. Nous avons évalué l'efficacité d'une méthode analytique qui se fonde sur la répartition des différentes tailles par classe d'age pour les deux stocks, afin qu'ils servent de modèles pour sélparer les prises mixtes en fonction des deux groupes d'appartenance. La méthode s'est révélée très efficace, groupe d'âge par groupe d'âge, lorsqu' on l'a essayee sur un ensemble de données synthétisé, comprenant des mélanges connus de ces deux stocks. Toutefois, l'utilisation de cette méthode pour distinguer deux stocks différents dans une pêche mixte nécessite des données précises sur la taille par classe d'âge pour les deux modèles qui représentent les deux stocks purs et pour la pêche mixte, durant l'année en question. Les prises dans 4 Vs ont été réparties parmi les sous-divisions 4 Vsb et 4 Vsc , afin de déterminer en quelles années on peut s'attendre à d'importantes prises de morue de $4 \mathrm{~T}-\mathrm{Vn}$ ( $\mathrm{J}-\mathrm{A}$ ). Les prises de la morue de 4 Vsb durant la pêche hivernale dans 4 Vs ont seulement dépassé le cap des 3000 t en 1982 et de 1986 à 1992 ( 10000 t en 1991). Une comparaison des tailles par classe d'age dans 4 Vn , 4 Vsb et 4 Vsc suppose que les tailles moyennes par classe d'âge de la morue de 4 V bb ressemblent davantage à celles de la morue de 4 T -Vn ainsi qu'à celles de la morue de 4 VsW , depuis quelques années. Nous avions assez de donnees pour calculer les prises de morue de $4 \mathrm{~T}-\mathrm{Vn}$ ( $\mathrm{J}-\mathrm{A}$ ) dans la pêche hivernale de 4Vs entre 1980 et 1991. Dans la mesure du possible, nous avons analysé séparément les données sur les prises des pêches hivernales dans 4 Vsb et 4Vsc (1986, et 1988 a 1992). Les prises estimatives de la morue de $4 \mathrm{~T}-\mathrm{Vn}$ (J-A) dans 4 Vsc variaient de 0 à 730 t durant cette période, contre 2300 t à 6300 t dans 4 V bb. Les prises estimatives de la morue de $4 \mathrm{~T}-\mathrm{Vn}$ ( $\mathrm{J}-\mathrm{A}$ ) durant la pêche hivernale de 1992 dans 4 V s étaient de 4170 t . Les prises estimatives de la morue de $4 \mathrm{~T}-\mathrm{Vn}$ ( $\mathrm{J}-\mathrm{A}$ ) dans la pêche hivernale de 4 Vsb representaient une moyenne de 55 p. 100 du total des débarquements de la morue de 4 Vsb (J-A) durant 1982, 1986 et de 1988 à 1992. Il n'y a actuellement aucune disposition à l'égard des prises de morue de $4 \mathrm{~T}-\mathrm{Vn}$ ( $\mathrm{J}-\mathrm{A}$ ) dans la pêche de 4 Vsb en vertu du plan de gestion actuel. Ce plan de gestion devrait être modifié pour tenir compte de ces prises.

## INTRODUCTION

One of the principal assumptions of analytical stock assessments is that the reported landings account for all of the catches from a particular stock. This requirement can become a problem if the species is migratory. It has long been known from tagging studies (e.g., McKenzie 1956; McCracken 1959; Powles 1959; Martin 1962; Martin and Jean 1964; Kohler 1975) that Atlantic cod from the $4 \mathrm{~T}-\mathrm{Vn}$ (Jan.-Apr.) stock primarily spend the winter in the Sidney Bight area (subdivision 4 Vn ; Fig. 1) and that some fish migrate as far south and east as Banquereau Banks (subdivision 4Vsc). Tagging studies also indicated that many of the cod caught during winter in the northern part of area 4 Vs (subdivision 4 Vsb ) were of $4 \mathrm{~T}-\mathrm{Vn}$ (Jan.-Apr.) stock origin (McCracken 1959; Powles 1959; Martin and Jean 1964). Because cod catches were thought to be small during winter in this area, the winter movements of $4 \mathrm{~T}-\mathrm{Vn}$ (Jan.-Apr.) cod beyond the 4 Vn boundary were not considered to be a problem in terms of managing the stocks. Consequently, detailed studies (including tagging studies with large numbers of fish) designed to determine the extent and variability of the winter migrations of $4 \mathrm{~T}-\mathrm{Vn}$ (Jan.Apr.) cod were never initiated. Recent changes in locations fished by the otter trawl fleet and biological evidence from the area 4 V s winter landings indicate that the extent of movements of cod from the $4 \mathrm{~T}-\mathrm{Vn}$ (Jan.-Apr.) stock outside of
the 4 Vn overwintering area needs to be reevaluated.
Cod from the 4T-Vn (Jan.-Apr.) stock are much smaller at age than those from the 4 VsW stock. During the 1991 assessment of the 4 VsW cod stock, Fanning and MacEachern (1991) noted that the average size-at-age of fish landed in the 1990 winter fishery was smaller than usual. Further, the length-at-age distributions for some age-classes appeared to be bimodal: one mode was near that of $4 \mathrm{~T}-\mathrm{Vn}$ cod during January to April and the second mode was near that of first-half-of-year catches in the 4VsW longline fishery. Based on these observations, the first quarter of 1990 catches from subdivision 4 Vs were visually partitioned into a $4 \mathrm{~T}-$ Vn (Jan.-Apr.) and 4 VsW stock components. Consequently, $7,656 \mathrm{t}$ of cod caught in the 4 Vs winter fishery were considered to be of $4 \mathrm{~T}-\mathrm{Vn}$ (Jan.-Apr.) stock origin and this amount was added to the catches of the $4 \mathrm{~T}-\mathrm{Vn}$ (Jan.-Apr.) stock and subtracted from catches of the 4VsW stock (Fanning and MacEachern 1991; Hanson et al. 1991). We recognized, however, that a more objective method was needed to partition the catches. In addition, ice-conditions during January to April 1991 and 1992 were similar to those observed during the 1990 winter fishery in subdivisions 4 Vn and 4 Vs , and it was thought likely that similar mixing of the stocks in the 4 Vs winter fishery had occurred.

Chouinard and Nielsen (pers. com.) used a maximum likelihood procedure (MacDonald and Pitcher 1979) to estimate the catch of $4 \mathrm{~T}-\mathrm{Vn}$ (Jan.-Apr.) cod in the 1991 winter fishery in the 4 Vs area. This method uses estimates of mean size-at-age and the associated variances for two stocks, taken when the stocks were separate, to calculate the proportions of the two stocks in a mixed population (i.e., the 4 Vs winter catch). One drawback of the method is that it requires the assumption of either a normal, lognormal, or gamma distribution for the data. Furthermore, it is tedious to use. Using this method, Chouinard and Nielsen estimated that $3,607 \mathrm{t}$ of the $12,806 \mathrm{t}$ of cod landed in area 4 Vs during January to April 1991 came from the 4T-Vn (Jan.-Apr.) stock. To avoid potential problems caused by assuming specific data distributions, we examined a method that uses length-at-age distributions directly to separate stocks from a mixed population and have used it to calculate catches of $4 \mathrm{~T}-\mathrm{Vn}$ cod in the 4 Vs winter fishery for as many years as possible.

There are two very similar techniques that use the Expectation Maximum algorithm with length-at-age distributions to calculate the proportions of two stocks in a mixed population. The Kimura and Chikuni (1987) method, which is used in this study, differs from the Hoenig and Heisey (1987) method in that the former assumes no sampling errors in the known length-at-age distributions. The two methods yield identical results when sample numbers are large (Hoenig and Heisey 1987), which is certainly the case in the expanded length-at-age distributions used to analyze commercial catches.

This study provides:
(1) a summary of catches and cod sampling in subdivisions 4 Vn and 4 V s during January to April since 1971;
(2) where sufficient samples exist, a comparisons of average lengths at age in the winter catches in $4 \mathrm{Vsb}, 4 \mathrm{Vsc}$, and 4 Vn to identify years in which there
may have been large numbers of $4 \mathrm{~T}-\mathrm{Vn}$ (Jan.-Apr.) cod caught during the 4 Vs winter fishery;
(3) a comparison of the length-at-age distributions from the 1990 winter fishery in 4Vs with those for the preceding quarter (October to December 1989) to determine whether the apparent bimodality in length-at-age distributions for the catches in the 1990 4Vs winter fishery were an isolated incident;
(4) an evaluation of how well the Kimura and Chikuni (1987) method separates mixtures of known proportions of the 4 T and 4 VsW stocks, in a synthesized data set, when: (a) only total length frequency distributions are available for the mixed samples and (b) when individual length frequency distributions are available for each age-class in the mixed samples; and
(5) estimates of landings and catches-at-age of $4 \mathrm{~T}-\mathrm{Vn}$ (Jan.-Apr.) cod in the 4 Vs winter fishery for as many years as possible, splitting the catches into the 4 Vsb and 4 Vsc subareas where sufficient samples were collected.
(6) estimates of catches and catches-at-age of $4 \mathrm{~T}-\mathrm{Vn}$ (J.-A.) and 4 VsW cod during the 1992 winter fishery in subdivisions 4 Vsb and 4 Vsc .

## DATA AND ANALYSES

Age-length distributions

The Kimura and Chikuni (1987) method requires accurate length-at-age distributions from each of the two stocks thought to contribute to a mixed sample to use as templates to partition the catches of the two stocks from the mixed population. Ideally, the templates are based on samples collected at the same time as the mixed population samples but from an area where the two stocks do not mix. This is to avoid changes in length-at-age distributions caused by seasonal growth. It is also necessary to have accurate length-at-age distributions for the period when the stocks are thought to be mixed because the method performs poorly when only a total length-frequency distribution is available for the period of mixing (see results). All length-at-age distributions used in this study were determined by means of the same age-length program that is routinely used in the $4 \mathrm{~T}-\mathrm{Vn}$ (Jan.-Apr.) and 4VsW cod stock assessments.

The length-at-age distributions routinely used for the 4 VsW cod stock assessment represent the January-March period rather than the January-April period of interest in this study. Therefore, we obtained the raw data for 4 VsW cod commercial catches since 1971 and ran length-at-age analyses (mobile gears only) for the period of potential mixing (January to April), the period immediately before the mixing (October to December - with one year added to each age), and for the period immediately after the potential mixing (May and June). Sampling intensity (i.e., numbers of otoliths collected) has varied widely in the 4 VsW stock during the 1971 to 1992 period included in this study (Table 1). For the presumed mixed populations, sufficient otoliths were available to permit
analysis for 1978 and 1980 to 1992. For the presumed pure 4VsW fish, there were very few otoliths collected during May and June in most years. Fortunately, there were adequate otoliths collected for the October-December period for most years between 1980 and 1992. For 1987, however, very few otoliths were collected during either the October-December 1986 or May-June 1987 periods and the samples for these two periods were combined to provide length-at-age distributions for the pure 4VsW stock.

Sufficient samples were available to calculate length-at-age distributions (mobile gears only) for $4 \mathrm{~T}-\mathrm{Vn}$ (Jan.-Apr.) cod from the winter fisheries in 4 Vn (Jan.-Apr.) for all years since 1971 (Table 1).

Catches in the $4 V s$ winter fishery

All available data on winter catches in 4 Vs were separated into catches in subdivisions $4 \mathrm{Vsb}, 4 \mathrm{Vsc}$, and 4 Vsu (unspecified) and summarized on a month-bymonth basis to determine whether fishing patterns have changed in recent years. Data from the Statistics Branch of the Scotia-Fundy Region were available from 1971 to present. Catch data were available from the Statistics Branch of the Newfoundland Region for 1985 to 1992. Unfortunately no data were available for the foreign fishery (primarily prior to 1977) and the official NAFO data do not separate the catches into 4 Vsb and 4 Vsc components. The mobile gear sector landed an average ( 1980 to 1992) of $95 \%$ of the total catches in the winter fishery. The fixed gear sector (mostly longlines) landed less than $1,000 \mathrm{t}$ annually during the same period (Table 2).

## Statistical Analyses

The utility of the Kimura and Chikuni (1987) method for separating catches of $4 \mathrm{~T}-\mathrm{Vn}$ (Jan.-Apr.) cod from mixed stock catches in the 4 Vs winter fishery was evaluated using two sets of synthesized data. The mixtures of known proportions of the two stocks were determined from the total length frequency or length-atage distributions for 1990 catches in 4 Vn (Jan.-Apr.) as the pure $4 \mathrm{~T}-\mathrm{Vn}$ (Jan.Apr.) cod data and October-December catches in 4 Vs during 1989 (one year added to each age) as the pure 4 VsW cod data. Both age-length analyses were run with catches of $10,000 \mathrm{t}$ to ensure that the total length frequency distributions and length-at-age distributions represented the same biomass of fish.

The first analysis used only the total length frequencies as the data for the mixed population. This analysis only assumes that the length frequency data routinely collected from the commercial fishery were representative of the catches. The total length frequencies for the two stocks when separate were combined at multiples of $10 \% 4 \mathrm{~T}-\mathrm{Vn}$ (Jan.-Apr.) fish, beginning at $0 \% 4 \mathrm{~T}$ fish. The Kimura and Chikuni method was applied to these synthesized mixtures using the length-at-age distributions (based on the actual landings) for the January to April $19904 \mathrm{~T}-\mathrm{Vn}$ catches and the October-December 1989 4Vs catches as the pure distributions (or templates). The program used to analyze these mixtures was run using the SAS/IML software (SAS 1989). The output consisted of the relative
proportions (by number) of each stock in the mixture (by age), length-at-age distributions, and a total length-frequency distribution for each stock. The appropriate length-weight regression was applied to the total length-frequency distribution to calculate the biomass of each stock in the mixture.

The second analysis used the same length-at-age data as above but analyzed the data age-by-age. This analysis assumes that sufficient otoliths were collected to be representative of both stocks in the catches. The program used in the analysis is the same as above, but modified for age-by-age analysis. The output consisted of length frequency distributions on an age-by-age basis and the proportion (by number) of each stock in the mixture (for that age-class). Biomass was calculated in the same manner described above.

## RESULTS AND DISCUSSION

Monthly catches in $4 V s b$ and $4 V s c$

Data on catches in the two subareas of 4Vs were incomplete prior to 1977 because data from the foreign fleets were not available. From 1971 to 1976, the available data represented 0 to $38 \%$ of the NAFO and ICNAF total catches (Table 3). Complete information on catches by subarea were available from Scotia-Fundy region since 1977, however, complete information on location of catches from Newfoundland Region was only available since 1985. Nevertheless, the available information since 1977 represents over $78 \%$ of the official landings from the NAFO Statistical Bulletins and were considered to be representative of the total catches for the purposes of this study.

The spatial distribution of catches during the winter months have clearly changed in recent years. Beginning in 1977, winter catches in 4Vsb have ranged between 325 t during 1978 to almost $10,000 \mathrm{t}$ during 1991 (Fig. 2). From 1978 to 1985, catches in 4 Vsb comprised 4 to $30 \%$ of the landings in 4 Vs during January to April. The catches in 4 Vsb since 1986 have comprised 28 to $73 \%$ of the total 4Vs landings. Sampling of the commercial catches did not change correspondingly. With the exception of 1991, 1992, and 1988 (and in 1988 numbers of otoliths collected were very low - $260^{\circ}$ otoliths for landings of $11,000 \mathrm{t}$ ), collections of otoliths since 1984 in 4 V sb have under-represented the catches by about $50 \%$. Now that a change in the pattern of the fishery has been identified, special effort is being made to collect sufficient otoliths to permit calculation of separate length-at-age distributions for areas 4 Vsb and 4 Vsc . The number of otoliths needed to permit stock separation is higher (roughly 400 otoliths for each of 4 Vsb and 4 Vsc in January-April and 4 VsW in October-December) than that required for simple age-determinations.

The temporal pattern of catches in 4 Vn and 4 Vs has not changed during the study period. For 1977 to 1991, the largest monthly catches in 4 Vn occur in January and February (Table 4); the largest monthly catches of cod in 4 Vsb were taken in February and March; and the largest monthly catches in 4 Vsc were taken in March and April. During 1992, the landings during January in 4 Vsb were the highest recorded since 1977. This temporal pattern in the fishery is not
surprising because many of the same boats fish in the three areas, moving out of 4 Vn as they reach their quotas and into 4 Vs (most recently 4 Vsb , then 4 Vsc ). In years when 4 T cod migrate extensively out of 4 Vn , such a fishing pattern would maximize the landings from the $4 \mathrm{~T}-\mathrm{Vn}$ (Jan.Apr.) stock.

The proportion of catches of unspecified 4 Vs origin have ranged between 0 and $6.5 \%$ of the total, since 1980 (Table 4). Where possible, these unspecified catches were apportioned to 4 Vsb and 4 Vsc in proportion to the landings in each subarea.

## Length-at-age analyses

Average lengths-at-age during January to April 1980 to 1991 for cod caught in subdivision 4 Vsb were compared to those in subdivisions 4 Vsc and 4 Vn to determine whether there were years when average lengths-at-age of cod caught in 4 Vsb might indicate significant movements of $4 \mathrm{~T}-\mathrm{Vn}$ (Jan. - Apr.) cod into 4Vsb. Caution is needed in interpreting these comparisons because sample sizes were small for 4 Vsb in some years. Average lengths of cod caught during January to April in 4 Vsb were intermediate between those of cod caught in 4 Vsc and 4 Vn in most years (Table 5). For 1983 and 1985, the average sizes-at-age in 4Vsb closely resembled those in 4Vsc. For 1990 to 1992 , the average sizes-at-age of 4 Vsb cod were very similar to those of $4 \mathrm{~T}-\mathrm{Vn}$ cod. Coincidentally, 1990 to 1992 were the three years of highest landings in 4Vsb during January to April (Table 3).

Fanning and MacEachern (1991) separated the winter 1990 catches in 4Vs into 4 T and 4 VsW components (mobile gears only) based on visual identification of modes. These length-at-age distributions and the dividing line used by Fanning and MacEachern are reproduced in Table 6 . For comparison, we have also included the October-December 1989 data for the 4 Vs cod stock, which also appears to show polymodal distributions, particularly for ages 7 to 11 . The same person did the age-determinations for both periods, thus age-determinations were consistent between periods. The causes of the apparent modes are unknown.

The positions of the 4 VsW modes used by Fanning and MacEachern (1991) were those of the 4 Vn winter fishery for $4 \mathrm{~T}-\mathrm{Vn}$ (Jan.Apr.) cod and those of the first half year longline catches in 4 VsW for the 4 VsW cod. The longline based length-at-age distribution overestimates the apparent differences in positions of modes between stocks because longlines catch larger individuals at age than mobile gears (here based on October-December 1989 samples with one year added to each age). Secondly, inclusion of May and June 1990 data means that some seasonal growth has already occurred, further increasing the apparent differences in average lengths-at-age between stocks. The average lengths-at-age in the 4 VsW cod longline and otter trawl landings were:

Average length-at-age of 4 VsW cod

|  | Age (y) |  |  |  |  |  |  |  |  |  |  |
| :--- | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: |
| Gear | 3 | 4 | 5 | 6 | 7 | 8 | 9 | 10 | 11 | 12 |  |
| Longline | 43.0 | 48.0 | 54.8 | 58.7 | 62.1 | 71.0 | 71.8 | 76.6 | 89.9 | 96.1 |  |
| Otter trawl | - | 44.6 | 47.8 | 51.2 | 54.5 | 60.5 | 58.0 | 57.0 | 68.5 | 67.8 |  |

These differences in average size-at-age (greater than 10 cm for cod age- 8 and older) would result in an overestimation of the size of the $4 \mathrm{~T}-\mathrm{Vn}$ cod component in the catches because they overestimate the average size of 4 VsW cod in the January to April fishery, which is primarily prosecuted by otter trawlers.

## Analysis of synthesized data

The method described by Kimura and Chikuni (1987) can only be applied on an age-by-age basis. The results of the analyses based only on overall lengthfrequencies in the mixed sample showed a strong symmetrical bias when the Kimura and Chikuni (1987) method was used to separate the mixture into the two stock components:
\%4T fish in test data (TEST) and as separated analytically (K \& C)

| TEST | 0 | 10 | 20 | 30 | 40 | 50 | 60 | 70 | 80 | 90 | 100 |
| :--- | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: |
| $K \& C$ | 17 | 26 | 33 | 42 | 49 | 56 | 62 | 67 | 73 | 79 | 83 |

Even when no 4 T cod were present, the analysis based only on the overall length distribution showed that significant numbers of 4 T cod were present in the mixture (and vice versa). Clearly, the Kimura and Chikuni (1987) method cannot be used with total length frequencies alone. In contrast, the method performed very well when used on an age-by-age basis.

There were very few differences between the proportions-at-age in the test data and those calculated on an age-by-age basis by the Kimura and Chikuni method (Table 7), and those differences were small (< 4\%). From these results, we concluded that the Kimura and Chikuni method could be used to estimate the
catches of $4 \mathrm{~T}-\mathrm{Vn}$ cod in the January-April fishery in 4 Vs where sufficient samples were collected from subdivisions 4 Vn and 4 Vs for both the period of mixing and from the period when the stocks were separate. Sampling of the $4 \mathrm{~T}-\mathrm{Vn}$ (Jan.-Apr.) stock for the January to April period by port samplers and the International Observer Program has been adequate to date. As noted earlier, numbers of otoliths collected in subdivision 4 Vs during the period of interest have varied substantially between years; this limits the number of years for which catches of $4 \mathrm{~T}-\mathrm{Vn}$ cod in the 4Vs winter fishery could be estimated (i.e., 1980 to 1992). More years could be analyzed if data from adjacent years could be used when the template for one or both pure stocks were missing.

Unfortunately, templates from adjacent years cannot be used in place of those for the year being analyzed. We examined the extreme case where both templates for 1990 pure stocks were replaced by templates from either 1989 or 1991. Neither templates based on 1989 nor 1991 length-at-age distributions adequately described the known 1990 mixtures (Table 8). This result was not unexpected. The technique was designed to be sensitive to differences between length-at-age distributions and significant annual variation in average length-at-age and length-at-age distributions is a normal occurence for samples collected from the commercial fisheries of nearly all fish stocks.

## Catches of $4 T$ cod in the $4 V s$ winter fishery

The estimates of catches of $4 \mathrm{~T}-\mathrm{Vn}$ cod in the 4 Vs winter fishery for 1980 to 1991 were first performed on all 4 Vs catches combined and, where sampling of otoliths permitted, on 4 Vsb and 4 Vsc catches separately. Estimates for 1992 were only based on 4 Vsb and 4 Vsc catches analyzed separately. Based on 4 Vs as a whole, the calculated landings of $4 \mathrm{~T}-\mathrm{Vn}$ cod between 1980 and 1991 ranged between 277 and $4,487 \mathrm{t}$ while landings in 4 Vsb ranged between 1,000 and $10,000 \mathrm{t}$ (Table 9). For all but 1990 and 1991, this represented less than 48 of the total $4 \mathrm{~T}-\mathrm{Vn}$ (Jan.Apr) catches. These were the two years when the average lengths-at-age of cod caught in 4 Vsb resembled those in $4 \mathrm{~T}-\mathrm{Vn}$ (Jan.-Apr.) more closely than those in 4 Vsc (Table 5) and the two years of highest catches in 4 Vsb . However, analyzing all 4 Vs data combined underestimated catches of $4 \mathrm{~T}-\mathrm{Vn}$ (Jan.-Apr.) in the 4 Vs winter fishery.

Sufficient otoliths were collected to permit calculation of catches-at-age of $4 \mathrm{~T}-\mathrm{Vn}$ (J.-A.) cod in 4 Vsb separately from those in 4 Vsc for 1982, 1986, and 1988 to 1992. With the exception of 1987, when few otoliths were collected in either subarea, these were the only years when greater than $3,000 \mathrm{t}$ of cod were landed from 4Vsb between 1 January and 30 April (Table 9). Estimated catches of $4 \mathrm{~T}-\mathrm{Vn}$ (Jan.-Apr.) cod in 4 Vsb were always much greater than those in 4 Vsc (Table 10) and represented on average $55 \%$ of the landings in 4 Vsb (see below). The estimated catches of $4 \mathrm{~T}-\mathrm{Vn}$ (J.-A.) cod in 4 Vsc ranged between 68 and 730 t whereas catches in 4Vsb ranged between 2,100 and 6,300 trom 1986 to 1992.

Since 1986, the catches of $4 \mathrm{~T}-\mathrm{Vn}$ (Jan.-Apr.) cod in subdivisions 4 Vsb and 4 Vsc combined represent a significant source of fishing mortality outside of the
$4 T-V n$ (Jan.-Apr.) stock area that is not accounted for in the Groundfish management plan:

Catches ( $t$ ) of $4 \mathrm{~T}-\mathrm{Vn}$ (Jan.-Apr.) cod in 4 Vs winter fishery when catches from 4Vsb and $4 V s c$ were analyzed separately.

| Year | 1982 | 1986 | 1987 | 1988 | 1989 | 1990 | 1991 | 1992 |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- |
| Estimated landings in 4Vs | 805 | 3,469 | 2,087 | 2,496 | 2,475 | 4,606 | 6,330 | 4,170 |
| As \% 4T-Vn (Jan. -Apr.) |  |  |  |  |  |  |  |  |
| landings in stock area |  |  |  |  |  |  |  |  |

The estimated landings of $4 \mathrm{~T}-\mathrm{Vn}$ cod in the 4Vs winter fishery during 1991 represented almost $17 \%$ of the catches in the $4 \mathrm{~T}-\mathrm{Vn}$ (Jan. -Apr.) stock area. The catches during the 1992 fishery in $4 V$ represents $9.7 \%$ of the total TAC for the $4 \mathrm{~T}-\mathrm{Vn}$ (Jan.-Apr.) stock and $17.1 \%$ of the allocation of the mobile gear fleet within Division 4 T (May to December 1992 fishery). These same catches also represented an overes'timation of fishing mortality on the 4 VsW stock during January to April 1986 to 1992 of 15 to $46 \%$. If only 4 Vsb is considered, the $4 \mathrm{~T}-\mathrm{Vn}$ (Jan. -Apr.) component has represented 26 to $77 \%$ of the landings in 4Vsb for 1982 and 1986 to 1992. There apparently was little movement of $4 \mathrm{~T}-\mathrm{Vn}$ (Jan.-Apr.) cod into 4Vs during January to April 1982 because estimated catches were 700 to 800 $t$ regardless of whether the analysis was performed separately on 4Vsb and 4Vsc or on 4 Vs as a whole.

The proportionately small catches of $4 \mathrm{~T}-\mathrm{Vn}$ cod in 4 Vsc compared to those in 4 Vsb (Table 10) are consistent with results of the tagging studies that indicated small numbers of $4 \mathrm{~T}-\mathrm{Vn}$ cod migrated as far as Banquereau Banks (in subdivision $4 V s c$ ) in some years (McKenzie 1956; McCracken 1959; Powles 1959; Martin 1962; Martin and Jean 1964; Kohler 1975). One effect of basing analyses on 4 Vs as a whole was that the large numbers of otoliths collected from 4Vsc, where there were few incursions of $4 \mathrm{~T}-\mathrm{Vn}$ cod, resulted in a significant underestimation of catches of $4 \mathrm{~T}-\mathrm{Vn}$ cod in 4 Vs . The estimated catches in 4 Vsb alone always exceeded those for 4 Vs analyzed as a whole, therefore, future analyses should be performed separately for subdivisions 4 Vsb and 4Vsc (as they were for the 1992 estimates). It is also important that the numbers of otoliths collected from the mobile gear fleet in $4 V \operatorname{sW}$ during October to December be sufficient (e.g., 400 or more) to permit calculation of an accurate template for the pure 4 VsW stock. The sampling of the commercial fishery in 4 VsW will be modified to meet these goals.

The estimated catches-at-age and biomasses of $4 \mathrm{~T}-\mathrm{Vn}$ (Jan. - Apr.) cod in the 4 Vs winter fishery from 1986 to 1991 (Table 10) were added to the catches of the $4 \mathrm{~T}-\mathrm{Vn}$ (Jan. - Apr.) stock and subtracted from the catches of the 4 VsW stock for the two assessments (Hanson et al. 1992; Mohn and MacEachern 1992). The estimates
based on separate analyses of 4 Vsb and 4 Vsc data were used for 1986 and 1988 to 1991. The analysis based on 4 Vs as a whole was necessarily used for the 1987 catches. Nevertheless, the estimated catch of $4 \mathrm{~T}-\mathrm{Vn}$ (Jan.-Apr.) cod in the 1987 winter fishery in 4 Vs was about $2,100 \mathrm{t}$.

The catch-at-age of the $4 \mathrm{~T}-\mathrm{Vn}$ (Jan.-Apr.) and 4 VsW components of the 4 Vs winter 1992 fishery have been calculated:

Catch-at-age (thousands) of $4 \mathrm{~T}-\mathrm{Vn}$ (J.-A.) and 4 VsW in 4 Vs during 1992 winter fishery

| Area/age | 3 | 4 | 5 | 6 | 7 | 8 | 9 | 10 | 11 | 12 | Total |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| $4 \mathrm{~T}-\mathrm{Vn}$ (Jan.-Apr.) component |  |  |  |  |  |  |  |  |  |  |  |
| 4Vsb | 0 | 135 | 793 | 181 | 428 | 701 | 283 | 183 | 135 | 58 | 2,897 |
| 4Vsc | 0 | 0 | 155 | 0 | 0 | 27 | 35 | 0 | 8 | 8 | 233 |
| Total | 0 | 135 | 948 | 181 | 428 | 728 | 318 | 183 | 143 | 66 | 3,130 |
| 4 VsW component |  |  |  |  |  |  |  |  |  |  |  |
| 4Vsb | 6 | 293 | 1920 | 2436 | 409 | 94 | 30 | 89 | 16 | 3 | 5,296 |
| 4Vsc | 10 | 47 | 295 | 542 | 238 | 112 | 14 | 33 | 10 | 12 | 1,313 |
| Total | 16 | 340 | 2215 | 2978 | 647 | 206 | 44 | 122 | 26 | 15 | 6,609 |

These catches-at-age will be used in the assessments of the two stocks in the coming year.

The estimated catch of $4 \mathrm{~T}-\mathrm{Vn}$ (Jan.-Apr.) cod in the 1990 4Vs winter fishery from this study was substantially lower than those provided by Fanning and MacEachern (1991); 4,606 t versus 7,656 t. As pointed out earlier, however, the visual separation of the stocks based on modes and length-at-age distributions from first half-year longline samples would overestimate the 4 T -Vn component in the mixed stock catches. The catches-at-age and biomasses of $4 \mathrm{~T}-\mathrm{Vn}$ cod in the 1990 winter fishery in 4 Vs were calculated using templates based on otter trawl data (October to December 1989) and longline data (January to June 1990) to illustrate the difference in estimates caused by the larger sizes-at-age of cod caught by longlines versus otter trawls:

Catch-at-age (1000s) and biomass (tonnes) of $4 \mathrm{~T}-\mathrm{Vn}$ cod landed in 4Vs during January-April 1990 based on longline (LL) and otter trawl (OTB) data.

|  | Age |  |  |  |  |  |  |  |  |  | - |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Gear | 3 | 4 | 5 | 6 | 7 | 8 | 9 | 10 | 11 | 12 | Biomass |
| LL | 0 | 58 | 809 | 1813 | 843 | 1102 | 733 | 882 | 101 | 36 | 8085 |
| OTB | 0 | 65 | 94 | 1082 | 602 | 276 | 709 | 824 | 5 | 0 | 4606 |

The estimated catch of $4 \mathrm{~T}-\mathrm{Vn}$ (Jan. - Apr.) cod calculated from longline data was almost twice that calculated from otter trawl data. The estimate based on the longline template, $8,085 \mathrm{t}$, was remarkably close to that estimated visually ( 7,656 t) by Fanning and MacEachern (1991). Because the winter fishery in 4Vs is prosecuted primarily by otter trawlers, the use of a template based on longline data was inappropriate.

Chouinard and Nielsen (pers. com.), using the MacDonald and Pitcher (1979) method, estimated that $3,607 \mathrm{t}$ of $4 \mathrm{~T}-\mathrm{Vn}$ cod were caught during the 1991 winter fishery in 4 Vs compared with 4,487 t estimated using the Kimura and Chikuni (1987) method on catches for 4 Vs as a whole in this study. These results are consistent and the difference between the two estimates likely reflects the assumptions about the shape of the length-at-age distributions required by the MacDonald and Pitcher (1979) method. No attempt was made to apply the method of MacDonald and Pitcher (1979) to the data separated into subareas 4Vsb and 4Vsc, which is the preferred method of analyzing the catch data for the winter fishery in 4 Vs .

Significant catches of $4 \mathrm{~T}-\mathrm{Vn}$ (Jan.-Apr.) cod have been taken in the winter fishery in 4 Vsb since 1986 and these landings have increased since then as total cod landings have increased in $4 V$ sb during January to April. It has long been known that significant numbers of $4 \mathrm{~T}-\mathrm{Vn}$ (Jan.-Apr.) cod migrate as far as 4 Vsb and this migration is expected to continue. Consequently, calculation of catches of $4 \mathrm{~T}-\mathrm{Vn}$ (Jan. - Apr.) cod will likely be an annual requirement as long as catches in 4Vsb continue at the levels observed since 1986. There is, however, no allocation of $4 \mathrm{~T}-\mathrm{Vn}$ (Jan. - Apr.) cod to the 4 Vs fishery in the current management plan. Nevertheless, these catches of $4 \mathrm{~T}-\mathrm{Vn}$ (Jan.-Apr.) cod must be included in the catch data used in the assessment of this stock and removed from the catch data used in the assessment of the 4 VsW stock. If resource managers wish to allocate catches of $4 \mathrm{~T}-\mathrm{Vn}$ cod to the 4 Vs winter fishery, then these catches must be counted against the TAC of the $4 \mathrm{~T}-\mathrm{Vn}$ (Jan.-Apr.) stock. If it is desirable to reduce exogenous catches of $4 \mathrm{~T}-\mathrm{Vn}$ (Jan. - Apr.) cod, catches from the 4 Vsb area should be brought under control by introduction of additional management measures. One such measure could be closure of the 4Vsb fishery from 1 January
to 30 April each year.

## ACKNOWLEDGEMENTS

The authors thank G. Chouinard, R. Jones, and H. Dupuis for reviewing the document, the members of the Groundfish Subcommittee of CAFSAC for their review and comments at the May 1992 meeting, and the members of the Statistics, Sampling, and Surveys Subcommittee of CAFSAC for their comments during the March 1992 meeting. Technical support was provided by J. Murphy and L. Currie.
