${ }^{1}$ This series documents the scientific basis for fisheries management advice in Atlantic Canada. As such, it addresses the issues of the day in the time frames required and the Research Documents it contains are not intended as definitive statements on the subjects addressed but rather as progress reports on ongoing investigations.

Research Documents are produced in the official language in which they are provided to the Secretariat by the author.
${ }^{1}$ Cette série documente les bases scientifiques des conseils de gestion des pêches sur la côte atlantique du Canada. Comme telle, elle couvre les problèmes actuels selon les échéanciers voulus et les Documents de recherche qu'elle contient ne doivent pas être considérés comme des énoncés finals sur les sujets traités mais plutôt comme des rapports étape sur les études en cours.

Les Documents de recherche sont publiés dans la langue officielle utilisée par les auteurs dans le manuscrit envoyé au secrétariat.

#### Abstract

Estimated river returns destined for Mactaquac, Saint John River, 1991, were 8,751 1SW and 5,215 MSW salmon. Homewater removals/losses of about 3,300 1SW fish indicate that 179 percent of the target number of 1SW spawners was met above Mactaquac. Returns and removal of just under 2,100 MSW fish resulted in an estimated spawning escapement above Mactaquac of 79 percent of the MSW target. Target egg requirements, which are largely dependent on MSW fish have been met only three times in the last 14 years (i.e., 1980, 1984 and 1985).

Combined wild and hatchery 1SW returns in 1991 were 95 percent of the preseason parametric forecast. MSW retums were 112 percent of the preseason forecast. Since 1986, returns of 1SW fish have equalled or somewhat exceeded forecast values; before use of the revised forecast model for 1991, returns of MSW salmon had been fewer than forecast.

A relationship between egg depositions and wild 1SW returns indicates fewer returns in 1992: 5,800 or 7,600 wild 1SW fish, depending on the forecast model. Another relationship between wild 1SW retums, their fork length and MSW returns suggests that the 6,300 1SW returns in 1991 will provide 3,900 or 4,200 wild MSW returns in 1992, depending on forecast model. The product of the numbers of hatchery releases and recent return rates suggest hatchery returns in 1992 of 2,000 1SW and 1,200 MSW salmon.

Total 1SW returns in 1992 could be 7,800 or 9,600 1SW fish; total MSW returns could be 5,100 or 5,400 MSW salmon. Spawning requirements are 3,200 1SW and 4,400 MSW salmon and do not include approximately 400 MSW broodstock required to seed Mactaquac Hatchery.

## RÉSUMÉ

En 1991, les remontées en direction de la Mactaquac, fleuve Saint-Jean, ont été estimées à 8751 saumons unibermarins (ayant passé un hiver en mer) et à 5215 saumons pluribermarins (ayant passé plusieurs hivers en mer). Les récoltes et pertes en eaux natales de 3300 saumons unibermarins environ montrent que l'objectif de géniteurs unibermarins en amont de Mactaquac a été atteint à 179 pour cent. Le retour et la récolte de près de 2100 pluribermarins ont donné lieu à une échappée de géniteurs en amont de Mactaquac estimée à 79 pour cent du nombre cible de pluribermarins. Les besoins cibles de la ponte, dont l'atteinte est largement fonction du nombre de pluribermarins, n'ont été satisfaits qu'à trois reprises seulement au cours des 14 dernières années (1980, 1984 et 1985).

Les remontées confondues d'unibermarins d'élevage et sauvages de 1991 se sont élevés à 95 pour cent de la valeur de la prévision paramétrique de pré-saison. Les remontées de pluribermarins correspondaient à 112 pour cent de la prévision de présaison. Depuis 1986, les remontées d'unibermarins ont égalé ou dépassé légèrement les valeurs prévues; avant l'utilisation du modèle de prévision révisé, en 1991, les remontées de pluribermarins étaient inférieures aux valeurs prévues.

Une relation établie entre la ponte et la remontée d'unibermarins sauvages indique une remontée plus faible en 1992, qui s'élève à 5800 ou 7600 unibermarins sauvages, tout dépendant du modèle de prévision. Une autre relation entre les remontées d'unibermarins sauvages, leur longueur à la fourche et les remontées de pluribermarins porte à croire que la remontée de 6300 unibermarins de 1991 donnera lieu à une remontée de 3900 ou de 4200 pluribermarins sauvages en 1992, tout dépendant du modèle de prévision. Le produit du nombre de poissons d'élevage relâchés et du taux des remontées récentes porte à croire que les remontées de poissons d'élevage de 1992 atteindront 2000 unibermarins et 1200 pluribermarins.

Les remontées totales d'unibermarins de 1992 pourraient s'élever à 7800 ou 9600 poissons tandis que les valeurs correspondantes de pluribermarins seraient de 5100 ou de 5400 poissons. Les besoins en géniteurs sont de 3200 unibermarins et de 4400 pluribermarins; ces valeurs ne comprennent pas les 400 géniteurs pluribermarins qui ont été nécessaires à la mise en marche de la pisciculture de la Mactaquac.

## INTRODUCTION

This document is background to the management of Atlantic salmon stocks of the Saint John River above Mactaquac, New Brunswick, and, as such, provides data and analyses relevant to stock status in 1991 and forecasts for 1992.

## BACKGROUND

Physical attributes of the Saint John River drainage, salmon production area, barriers to migration, fish collection and distribution systems, the role of fish culture operations and status of the salmon stocks since 1970 have previously been described by Marshall (1989). Forecasts made in 1990 suggested that 1991 homewater returns to Mactaquac would number approximately 9,900 or $11,0001 \mathrm{SW}$ and 4,700 or $5,200 \mathrm{MSW}$ salmon, depending on forecasting technique (Marshall 1991).

The Management Plan for 1991 was identical to that of 1990 in that there was a total ban on homewater commercial fisheries, a prohibition on the retention of MSW salmon captured in the sport fisheries and the same open seasons for sport fishing. The Kingsclear Indian Band guided a sport fishery as in the previous few years and reported catch statistics.

New, however, was a native fishery with gill nets on the main Saint John between Mactaquac and Fredericton, near Gagetown and in the lower reaches of the Nashwaak River. No catch statistics were provided. The Oromocto Band fished two trap nets on the main river near Oromocto under an "Agreement" with DFO and reported catch statistics. A food fishery with gill nets was also conducted above and below the Tobique Narrows Dam on the Tobique River. Catch statistics for that fishery were provided, but are, in part, known to be erroneous.

Mean daily river discharges at Mactaquac in June, July and August, 1991, were among the lowest of the last 20 years (Fig. 1). 1SW returns to Mactaquac were later than usual (Fig. 2). The low discharge, lateness of 1SW returns, in-season predictions that MSW spawning requirements above Mactaquac would not be met, unexplained scale loss/ fishing gear-like injuries to $68 \%$ of MSW and $22 \%$ of 1 SW salmon collected at Mactaquac and the concern about the impact of the new in-river net fisheries contributed to the convening of SFA 23 salmon management advisory meetings (ZMACs) in each of July and August.

## METHODS

## Returns destined for Mactaquac

Total returns of 1SW and MSW salmon of both wild and hatchery origin from and above Mactaquac Dam consist of the summation of Mactaquac counts, estimated angling (including Kingsclear Indian Reserve) and native netting in the mainstem below the Mactaquac Dam and estimated by-catch in downriver shad, gaspereau and "other" species net fisheries.

Mactaquac counts consist of those fish captured at the fish collection facilities at the Mactaquac Dam and at the smolt migration channel at the Mactaquac Fish Culture Station. As in 1990, fish collection facilities were open a "full" season. The identification of 1SW and MSW returns from 1-year and a smaller number of 2-year smolts released at Mactaquac and juveniles
released above Mactaquac was dependent on fin clips (adipose) and fin erosion (principally dorsal fin). By-catch was estimated to be $2 \%$ of the 1 SW and $5 \%$ of the MSW river returns - values which approximate the mean estimates for the years 1981-1984. The by-catch, sport and native catches below Mactaquac were assumed to consist of fish of hatchery and wild origins in the same proportions as those counted at Mactaquac.

## Removals of fish originating at/above Mactaquac

Removals include calculated numbers of fish taken in the native fishery on the mainstem below Mactaquac and on the Tobique River; provincial, federal and native statistics for sport catch on the mainstem below Mactaquac, on the mainstem above Mactaquac (inc. Salmon River, Victoria Co.,) and the Tobique River; and a by-catch in the estuary.

Estimates of the numbers of salmon harvested by natives in up to 14 nets, mostly 5.0-5.5 in (127-140 mm) mesh below Mactaquac, i.e., Harts and Savage islands and at McKinley Ferry (all between $2-9 \mathrm{~km}$ below the Dam) were based on 89 MSW and 35 1SW fish observed by Fishery Officers who visited the sites on 14 mornings between July 7 and Sept 30 and daily counts at Mactaquac Dam.

Native fisheries also operated at the mouth of and within the Nashwaak River. Landings were estimated by Fishery Officers to have been 100-150 "salmon" which I attributed to a belowMactaquac origin. The harvest from trap nets at Oromocto and Upper Gagetown were reported by Fishery Officers and apportioned to an above- (0.68) and below- (0.32) Mactaquac origin in accordance with the production area estimated for above Mactaquac relative to that of the Nashwaak and Keswick rivers below Mactaquac (Marshall and Penney 1983).

The estimated gill net catch by the Tobique Band, June - Sept, was based on the total catch compiled by the Band after an "Agreement" was signed with DFO in late October. Fishing was conducted below the Tobique Narrows Dam (2-3 nets) and in the Tobique Headpond (6-8 nets). The reported ratio of 1SW:MSW was found to be inconsistant with ratios developed from adult releases and fishway counts and was therefore discarded in favor of the ratio reported by the Band in 1991 when catch statistics were compiled during the fishery.

Other removals include: fish monitored through the fish-lift at Tinker Dam on the Aroostook River, trucked from Mactaquac to above Tinker Dam and from Mactaquac to above Grand Falls, retained at Mactaquac for broodstock, and mortalities encountered during collection-handling operations or sacrificed for analysis. Losses of MSW fish to hook-and-release mortality were estimated at $2 \%$ of the run placed above Mactaquac (exclusive of those estimated to have been taken in the Tobique net fishery or passed into the Aroostook and above Grand Falls) i.e., similar to a previously used $10 \%$ loss on estimated MSW sport catch. Losses to poaching and disease ascribed in recent assessments, i.e., $4 \%$ of 1SW and $10 \%$ of MSW fish placed above Mactaquac (exclusive of those estimated to have been taken in the net fishery at Tobique or passed into the Aroostook or above Grand Falls) were calculated in 1991 but regarded as "spawners". For the most part, losses were apportioned to hatchery/wild components on the basis of estimated stock composition.

## Required Spawners

An accessible salmon-producing substrate of $12,261,000 \mathrm{~m}^{2}$ above Mactaquac, (exclusive of the main Saint John below Grand Falls, the Aroostook River and main Saint John and tributaries above Grand Falls), an assumed requirement of $2.4 \mathrm{egg} / \mathrm{m}^{2}$, a length-fecundity relationship ( $\log _{6}$ Eggs $=6.06423+0.03605$ Fork Length) applied to MSW and 1SW fish, 19721982, and the 1SW:MSW ratios in those years suggest that, on average, approximately 4,400 MSW fish are required above Mactaquac (Marshall and Penney 1983). Because 1SW fish normally contribute so few eggs (usually fewer than $5 \%$ females) a management philosophy limits 1SW requirements to that number which provides males for MSW females unaccompanied by MSW males, i.e., 3,200 fish (Marshall and Penney op. cit.).

## Stock Forecasts

## 1SW Wild

One forecast of wild 1SW returns originating above Mactaquac was derived from a regression of total wild 1SW fish returning to the Saint John River which were produced above Mactaquac, 1973-1989, on adjusted (method in Penney and Marshall 1984, with updates on freshwater age composition from wild 1SW fish, App. 1, 2 and 3 this paper) egg depositions in the Tobique River, 1968-1969 to 1984-1985. The 1987 and 1988 egg depositions, principal contributors to 1 SW returns in 1992, were derived using angular-transformed mean proportions for age 2.1 and age 3.1 1SW fish in the previous decade. Previous use of the entire 18 years included two years with values quite different from those of the last 10 years.

To make multiplicative effects of environment, competition, variability in recruits etc. amenable to linear regression analysis, the natural logarithms of the observed values were used (Ricker 1975). The geometric mean (GM) Y resultant of the logarithmic relationship was converted to an arithmetic mean (AM) by the formula $\log _{10}(\mathrm{AM} / \mathrm{GM})=0.2172 \mathrm{~s}^{2}(\mathrm{~N}-1) / \mathrm{N}$, where $s$ is the standard deviation from the regression line of the normally-distributed natural logarithms of the variate (Ricker 1975, p. 274). A second forecast of wild 1SW returns in 1992 was derived with a nonparametric probability density function described by Noakes (1989) and the above logged egg and grilse data.

## MSW Wild

Recent approaches to forecasting MSW returns have focused on the use of parametric and nonparametric statistics and three variables: log MSW returns in year i+1, 1SW returns and fork length of 1SW returns in year $i$ (Marshall 1991). This assessment provides forecasts of MSW returns in 1992 using current data, the regression of logged MSW returns on 1SW returns and fork length of 1SW returns, and a joint probability density function for three variables in steps, each using only two variables, i.e., the first step constructs the joint probability density function of MSW salmon returns and 1SW returns, the second step uses the residuals from step 1 and the 1SW lengths to produce the forecast and confidence limits. Harvie and Amiro (1991) detail the steps in constructing a joint probability density function using two variables and the procedure by which the multivariate smoothing parameters were determined.

## 1SW Hatchery

Since the deployment of 1-year smolts from Mactaquac in 1985, forecasts of hatchery returns have been simply the product of the mean return rate of recent years and the number of smolts (i.e., $>12 \mathrm{~cm}$ ) expected to contribute to 1 SW returns. The return rate for age 1.1 fish retuming to Mactaquac in 1991 was assumed to be the same as the mean (arcsine) of the 19881991 'adjusted' retum rates (App.4). Age 1.1 returns were adjusted by removal of the estimated returns to Mactaquac from smolts released in tributaries below Mactaquac (Marshall 1990). A 7 -year mean ratio (return rate of tagged 1SW fish to Mactaquac from smolts released at Mactaquac: return rate of tagged 1SW fish to Mactaquac from smolts reared at Mactaquac but released below Mactaquac) of 1:0.21 was used for the 1992 returns.

Additional 1SW returns of age 3.1 and age 2.1 are expected at Mactaquac in 1992 from fall fingerlings (age $0^{+}$) graded from the 1 -year smolt program at Mactaquac and released in tributaries above Mactaquac in 1988 and 1989. Similarily, returns are expected from fall fingerlings acquired by others for release to the Aroostook River and main Saint John above Grand Falls. Returns of age 2.1 's were forecast as the product of a 0.0006 return rate to Mactaquac (an intermediate value from releases of marked and unmarked fall fingerlings above Mactaquac in 1988) and the numbers released in 1989. Age 3.1's were assigned a return rate of 0.5 that given the age 2.1's. Returns from unfed fry were accorded a return rate of 0.5 of that given the fall fingerlings but are unlikely to be distinguishable from wild fish upon return to Mactaquac.

## MSW Hatchery

Returns as MSW fish from 1-year smolts released at Mactaquac in 1990 were estimated as the product of the number released and the adjusted mean (arcsine) return rate for 1-year smolts released from Mactaquac 1986-1989 (App.4). As with 1SW hatchery returns, MSW fish destined for Mactaquac from releases to tributaries below were proportioned ( 0.24 ) on the basis of MSW tag returns to Mactaquac from six different smolt classes.

As well, MSW returns of age 3.2 and age 2.2 are expected from fall fingerlings released above Mactaquac in 1987 and 1988. Returns of age 2.2 salmon were forecast as the product of their numbers and a return rate to Mactaquac of approximately 0.5 of that exhibited by those fish which returned as 1SW fish in 1991 (App. 5). Age 3.2 hatchery MSW fish, a rarity (App.5) because of the generally large size of stocked fall fingerlings, were accorded a liberal rate of approximately 0.5 of that of age 2.2 fish.

Hatchery fish which returned as maiden fish, principally 1988-1991, are expected to comprise the repeat-spawning MSW component in 1992. This return, which has in the past been less than 0.5 of the forecast, was simplified and assumed to equal the proportion that repeat spawners comprised of all MSW returns in 1991, i.e., 0.07 (App. 4).

## RESULTS

## Returns destined for Mactaquac

Estimated homewater returns in 1991 totalled 8,951 1SW and 5,255 MSW fish (Table 1). Retums included 450 1SW and 728 MSW fish estimated to have been taken in the Native fishery, 551 1SW fish taken in the sport fishery and 175 1SW and 261 MSW fish allotted to by-catch, all below Mactaquac. Counts of fish at Mactaquac in 1991 comprised $87 \%$ of 1SW and $81 \%$ of MSW returns estimated to have been destined for Mactaquac. Hatchery fish comprised 28\% and 14\% of those 1SW and MSW counts, respectively (Fig. 3).

Landings in the net fishery just below Mactaquac were based in part on the regression of MSW catch on MSW counts at Mactaquac the following day (MSW $H_{\text {avest }}=0.1654 \mathrm{~F}_{\text {ishway count(day }+1 \text { ) }}$ $+1.879 ; r^{2}=0.343 ; n=14: p<0.05$ ) for the 14 mornings for which there were observations of net catch. Regression of MSW catch per net on fishway counts was not significant. A MSW harvest of 701 fish was estimated by substitution of the season-end count at Mactaquac in the above equation. The observed numbers of net-caught 1SW salmon alone or per net did not correlate with counts at the fishway. An estimated harvest of 341 1SW fish was based on a ratio of observed catch to fishway count of 0.045:1.0. Exploitation rates implied by these estimates of 1SW and MSW salmon approximate the average values of 0.04 and 0.22 estimated for the Kingsclear net fishery in the early 1980's (Marshall 1985). An estimated harvest by Natives of 160 1SW and 40 MSW fish in the vicinity of Oromocto was interpreted as a removal of 109 1SW and 27 MSW fish originating above Mactaquac.

## Removals

Sport 1SW removals additional to those reported by the Kingsclear Band and NBDNRE in the lower main stem consist of 1,139 fish above Mactaquac (Table 2). The Tobique Indian Band reported a net harvest of 436 salmon, estimated to be comprised of 207 1SW and 229 MSW salmon. The catch was assumed to consist of hatchery and wild 1SW and MSW fish in proportions similar to those estimated to have been available to the fishery.

MSW losses above Mactaquac to poaching and disease combined were set at $10 \%$ (exclusive of those taken in the net fishery and passed above Tinker Dam and Grand Falls) as in recent years. No special account was given to the fact that $68 \%$ of all MSW salmon observed at Mactaquac had some scale loss/injury, river discharge was unusually low and water temperatures somewhat high. 1SW losses to poaching and disease were set at 4\% (exclusive of those taken in the Tobique net fishery and passed above Tinker Dam and Grand Falls). Known losses were similar to those of 1990; furunculosis was again detected in mortalities recovered by NBDNRE from Half Mile Pool on the Tobique River.

Removals by all factions were estimated at 3,304 1SW fish of which 179 made their way above Tinker Dam and Grand Falls and 2,089 MSW salmon of which 100 were transferred above Tinker Dam and Grand Falls. Hatchery broodstock retained at Mactaquac numbered 321 MSW salmon; 329 1SW salmon were sacrificed, mostly to recover nose wire tags, check on external sexing or have disease tested. Most of the carcases were distributed on two Indian Reserves close to Mactaquac.

## Spawning Escapement

Collation of the total returns (Table 1), total removals (Table 2) and numbers of fish required on average to meet an egg deposition of $2.4 \mathrm{eggs} / \mathrm{m}^{2}$ indicate that $3,481(79 \%)$ of the required 4,400 MSW spawners were attained above Mactaquac (Table 3). For 1SW fish, 179\% of requirements were met above Mactaquac. An estimated $15 \%$ of wild (based on internal sexing of 80 fish in July and extemal sexing from September onwards) and 7\% of hatchery 1SW fish (based on Sept-Oct) were female and with respective mean lengths of 57.8 and 58.7 cm had the potential to deposit about 2.5 million eggs. This number of eggs is $8 \%$ of the $2.4 \mathrm{egg} / \mathrm{m}^{2}$ target or the equivalent of about 320 MSW females.

## Stock Forecasts

## 1SW Wild

A 1992 forecast of wild 1SW fish returning to Mactaquac in the absence of homewater removals was based on the regression of returns to homewaters of 1 SW fish which originated above Mactaquac on estimated Tobique River egg depositions adjusted for smolt age. The AM estimate for 1SW returns in 1992 is 5,786 1SW fish ( $90 \%$ C.L. $4,983-6,717$; Table 4). For 1991, the method had forecast $6,481(5,470-7,680)$ 1SW fish; 6,256 fish were estimated to have returned.

A forecast of $7,603(90 \%$ C.L. 2,105-10,262) 1SW fish was obtained from the probability density function in which maximum likelihood smoothing parameters were 0.80 (eggs) and 0.38 (1SW fish) (Table 4). This forecast is virtually identical to the 1991 forecast.

## MSW Wild

A forecast of 3,931 ( $90 \%$ C.L. 2,252-6,863; Table 4) wild MSW fish destined for Mactaquac in 1991 was derived from the equation $\log _{\mathrm{e}} \mathrm{MSW}=24.013+0.127 \mathrm{E}-3$ 1SW -0.286 Length ( $\mathrm{R}^{2}=0.547 ; \mathrm{p}<.001$ ). For 1991, the method forecast 3,415 returns in $1991 ; 4,491$ fish were estimated to have returned. The probability density estimator (3-variables in two steps) for the same data provides a forecast of 4,211 ( $90 \%$ C.L. 0-16,271) MSW fish (Table 4) - higher than the forecast of 3,985 fish for 1991.

## 1SW Hatchery

The forecast of hatchery 1SW fish destined for Mactaquac in 1992 was in part calculated as the product of an estimated 178,127 one- and two-year smolts ( $25 \%$ less than the number contributing to 1991 returns) released at Mactaquac and an adjusted 0.0062 return rate (Table 5 ), i.e., 1,104 fish. Another 154 and 48 should return from smolts placed above and below Mactaquac, respectively. In addition, it was estimated that fall fingerlings released above Mactaquac, and in the Aroostook River in particular, in 1988 and 1989 would contribute another 511 1SW fish (Table 5) - about one-third of the number forecast to return in 1991. The total forecast of hatchery 1SW returns to Mactaquac is 2,027 1SW fish. The 1991 forecast by these methods exceeded returns by about $25 \%$, principally because fall fingerlings, especially those placed above Grand Falls, returned at only about one-quarter of the forecast 0.0017 return rate (App. 4 and Marshall 1991, Table 5)

## MSW Hatchery

MSW returns destined for Mactaquac in 1992 were calculated as the sum of the product of an estimated return rate of 0.0029 and 241,078 smolts released at Mactaquac in 1990 (699 fish) and 0.24 of returns from 48,105 smolts released below Mactaquac in 1989 ( 33 fish). Additional retums are expected from fall fingerlings released in 1987 and 1988 and low (lower than previously used) 0.0001 and 0.00025 survival/return rates (Table 5). The forecast of total hatchery MSW returns to Mactaquac, including repeat spawners, is 1,205 MSW fish (Table 5).

## Forecast Summary

The forecast of total homewater returns to Mactaquac, Saint John River in 1992 is 7,813 or 9,6301 SW ( 5,786 or 7,603 of wild and 2,027 hatchery origin) and 5,136 or 5,416 MSW fish ( 3,931 or 4,211 of wild and 1,205 of hatchery origin). Forecast returns minus the spawning requirements of $3,2001 \mathrm{SW}$ and $4,400 \mathrm{MSW}$ salmon result in potential surpluses of 4,613 to 6,430 1SW and 736 to 1,016 MSW salmon.

## DISCUSSION

Estimated returns in 1991 of 8,751 wild and hatchery 1 SW and 5,215 wild and hatchery MSW salmon were $95 \%$ and $112 \%$ of returns predicted by parametric methods. Comparisons of predicted and actual (estimated) returns for each of wild and hatchery fish since 1985 are as follows:

| Sea-age | Returns | 1985 | 1986 | 1987 | 1988 | 1989 | 1990 | 1991 |
| :--- | :--- | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Wild |  |  |  |  |  |  |  |  |
| 1SW | Predicted | 7,063 | 5,075 | 4,989 | 6,054 | 8,197 | 7,393 | 5,786 |
|  | Returned | 6,526 | 7,904 | 5,909 | 8,930 | 9,522 | 7,263 | 6,256 |
|  | Ret/Pred | 0.92 | 1.56 | 1.18 | 1.48 | 1.16 | 0.98 | 1.08 |
|  |  |  |  |  |  |  |  |  |
| MSW | Predicted | 8,413 | 7,702 | 8,327 | 6,983 | 6,232 | 6,325 | 3,415 |
|  | Returned | 10,436 | 6,128 | 4,352 | 2,625 | 4,072 | 3,329 | 4,491 |
|  | Ret/Pred | 1.24 | 0.80 | 0.52 | 0.38 | 0.65 | 0.53 | 1.32 |

## Hatchery

| 1 1SW | Predicted | 4,292 | 117 | 2,319 | 2,165 | 2,080 | 2,710 | 3,400 |
| :--- | :--- | ---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | Returned | 2,018 | 862 | 3,328 | 1,250 | 1,339 | 1,541 | 2,495 |

[^0]MSW returns, including fish of hatchery origin, were the seventh lowest of a 17-year data set, but the highest since 1986 (Table 6). Returns of wild 1SW fish above Mactaquac were 108\% of predicted; wild MSW fish above were $132 \%$ of the predicted value. Hatchery 1SW and MSW returns were $74 \%$ and $57 \%$ of forecasts.

Estimated harvests in the various net fisheries increased to pre- 1987 levels (Table 7) before a cooperative "Agreement" was reached with the Kingsclear Band. Indeed, new net removals immediately below Mactaquac in 1991 were variously rumored to have been as many as 3,000 fish - a number that would seriously jeopardize the on going estimation of adult returns and forecasts of returns. Whatever the level of removal, spawning escapement of MSW fish, including estimated losses to poaching and disease, was $79 \%$ of requirement - the same as in 1989 and the best since 1986, if mortality of the many "scaled" fish did not exceed that allowed in the assessment. Deficits in MSW spawning escapement, 1986-1991 (80, 63, 39, 79, 73, and 79\% of requirements), and likely losses to net fisheries should deter managers from allocating predicted surpluses during the next several years.

For the first time in five years, wild MSW returns have equalled/exceeded those predicted. Investigations by Ritter et al. (1990) determined that the inclusion of fork length of returning 1SW salmon (perhaps the most overlooked and best measured potential expression of annual variation in growth conditions - likely marine but not excluding freshwater) in the original 1SW:MSW forecast models permitted prediction of recent declines in MSW returns. MSW returns declined as 1SW returns and their length increased, i.e., better early growth at sea may lead to earlier maturation and return of normally non-maturing salmon.

A measure of "crossover" had been annually sought through changes in the sex ratio of mature 1SW fish but changes were not found to be significant, perhaps because extemal sexing of early-run 1SW fish was inaccurate. Internal sexing of 80 1SW fish in July 1991 indicates that external sexing of summer-run 1SW fish may miss some females and that Sept-Oct external sexing may more adequately reflect the male:female ratio of the entire 1SW run. A second year of testing may well contribute to a reexamination of 1SW sex information available for inclusion in the forecast model. Other hypotheses for the decline in MSW returns include proportionately greater exploitation of non-maturing 1SW fish in distant fisheries, proportionately less exploitation on maturing 1SW fish and sea conditions contributing to more/less natural mortality.

Forecasting of hatchery returns continues to be problematic, although in most recent years, the predicted and actual returns have comprised less than $20 \%$ of the run. Returns in 1991 were at least not complicated by the identification of potential sea-cage escapees - none were recorded. Of particular difficulty, however, is the forecasting of returns from juveniles originating in other hatcheries and stocked in a less discriminating manner than products from DFO hatcheries.

## ACKNOWLEDGEMENTS

Compilation and synthesis of this assessment has been made possible only with the support of provincial and federal co-workers. Fish count and removal information was provided by the staff at Mactaquac FCS, Fishery Officers in Fredericton, Plaster Rock and St. Leonard and P. Cronin, NBDNRE, Kingsclear. C.J. Harvie, DFO, Halifax, provided forecasts from non-parametric probability functions and R.E. Cutting, DFO, Halifax, reviewed the manuscript.

Harvests: MSW salmon have not been retained since 1984; up to 1990, 1SW landings have ranged from 311 in 1972 to 3,580 in 1976. In 1991 the native fishery had the highest total landings since 1986; the absence of complete catch statistics seriously hampers the stock assessment and forecasting processes.

Data and methodology: Counts of fish obtained from the collection facility at Mactaquac Dam; returns to Dam equal counts plus estimates of down river removals. Spawners equal releases above Mactaquac minus estimates of upriver removals.

State of the stock: Target egg requirements have been met only three times in the last 14 years (1980, 1984, 1985); 1SW escapement contributed to only $8 \%$ of the target egg deposition; hatchery fish comprised $14.5 \%$ and $28.5 \%$ of 1 SW and MSW returns in 1991.

Forecast: A relationship between egg depositions and wild 1SW returns indicates a return of 5,800 or 7,600 wild 1SW fish, depending on the forecast model. Another relationship between wild 1SW returns, their fork length and MSW returns suggests that the 6,300 1SW returns in 1991 will provide 3,900 or 4,200 wild MSW returns, depending on forecast model. The product of the numbers of hatchery releases and recent return rates suggest hatchery returns in 1992 of 2,000 1SW and 1,200 MSW salmon. Total 1SW returns could be 7,800 or 9,6001 SW fish; total MSW returns could be 5,100 or $5,400 \mathrm{MSW}$ salmon. Target spawning requirements do not include 400 MSW broodstock required to seed Mactaquac Hatchery.

${ }^{2}$ Includes returns from downriver stocking of smolts, 1981-1991; adjusted return rate excludes downriver returns to Mactaquac (Marshall 1989). (Marginal numbers of returns from approx. 5,000 age 2.1 smolts not inc., 1989-'91.)
${ }^{\circ}$ 1SW hatchery fish at Mactaquac were approximated at $0.690,0.106,0.172$ and 0.032 from smolts released "at" and above and age 2.1 and 3.1 fall fingerlings released above, respectively. MSW hatchery fish at Mactaquac were estimated at $0.645,0.077,0.198,0.008$ and 0.072 from smolts "at" and "above", and age 2.2, 3.2 fall fingerlings and 'repeats', respectively.

App. 5. Estimates of hatchery 1SW and MSW returns to Mactaquac, Saint John River, 1991, as estimated from numbers of various juveniles released at (At), above (Abv) or below (BI), Mactaquac and estimated returns to Mactaquac.

${ }^{\text {a }}$ Inc. two groups of CWT Ad-clipped fish released at Mactaquac.
b Downstream passage trials above Mactaquac.
${ }^{\text {c }}$ Inc. 727,400 fall fings. and 167,600 fry distributed by SALEN and 42,282 fry and 27,350 1-yr smolts distributed by Maine to Aroostook River.
${ }^{d}$ See Marshall (1990) App. 5 and footnote d, Table 5 this document; 2SW value set equal to 1 SW value.

- App. 4.
${ }^{\dagger}$ Not distinguishable from wild smolts.
${ }^{9}$ Based on proportions, footnote App. 4.

[^0]:    ${ }^{\text {a }}$ First returns from 1-year smolts.

[^1]:    ${ }^{\text {a }}$ Derived from App. 2 and 3.
    ${ }^{b}$ Mean (of last 10 years) calculated with angular transformation.
    ${ }^{\text {c }}$ Revised from Marshall (1991).
