Comme telle, elle couvre les problèmes actuels selon les échéanciers voulus et les Documents de recherche qu'elle contient ne doivent pas être considérés comme des énoncés finals sur les sujets traités mais plutôt comme des rapports d'étape sur les études en cours.**

**Les Documents de recherche sont publiés dans la langue officielle utilisée par les auteurs dans le manuscrit envoyé au secrétariat.**

### **Abstract**

Simulations using modified catch equations, observed average weights at age and fishing patterns were conducted to determine the expected yield for the southern Gulf of St. Lawrence cod stock with and without a winter fishery. Results show that there is essentially no difference in expected yield under these two conditions.

### **Résumé**

Des simulations réalisées avec des équations de capture modifiées, les poids moyens et les patrons de pêche (recrutement partiel) observé ont été effectuées pour déterminer le rendement attendu pour le stock de morue du sud du Golfe du St. Laurent avec et sans pêche d'hiver. Les résultats indiquent qu'il n'y a essentiellement pas de différence dans le rendement sous ces deux conditions.

### **1) Introduction**

Growth, geographic distribution of fish according to size and selectivity of gears are all factors that can affect the yield that can be obtained from fish stocks. For example, exploiting a stock later in the year after growth has taken place may produce an increase in yield providing that the fishery at that time is not prosecuted with less selective gears and that the size-structure of the population available to the fishery is not characterized by more small fish. If the rate of growth is low then losses due to natural mortality may also outweigh any gains in yield.

The southern Gulf of St. Lawrence cod stock (4T-Vn (J-A)) undergoes an extensive annual migration. During the late spring, summer and fall, the population is found in the southern Gulf of St. Lawrence where it is exploited by inshore vessels (less than 15 m L.O.A.) and midshore vessels (15 - 30 m L.O.A.) fishing with otter trawls, Danish and Scottish seines and fixed gears (longlines and gillnets). In recent years, this fishery has accounted for between 70 and 80% of the landings. During the fall (October - December), the population migrates from the western sections of NAFO 4T (4Tkln) to the eastern areas (4Tfg) and then to the Sydney Bight area (4Vn). During the winter, the stock is primarily exploited in 4Vn by offshore vessels from Canada and France. In 1992, the original allocations in 4Vn amounted to 7,024 t (including 1,600 t for France), or 16.3% of the total TAC of 43,000 t for the stock. The remainder of the quota was allocated to fleets fishing in 4T.

A study conducted in 1987 (Chouinard and Sinclair 1987) examined the implications of a closure of the winter fishery (4Vn (January-April)) in terms of the yields that could be obtained from the stock. It was concluded at the time that an increase in yield of about 3% could be expected if the fishery was conducted exclusively in 4T. This increase was considered marginal and given the expected year-to-year variations, it was concluded that a fishery conducted only during the summer would not significantly increase the yield

from the stock.

Data used in the earlier work covered the early 1980's. Since then, many changes have occurred; there have been significant changes (reduction) in average weight-at-age, the proportion of the catch caught by fixed gears has decreased markedly, the proportion taken by France has also decreased and an Enterprise Allocation (EA) program has been introduced for many fleets. Given these changes, it was considered appropriate to revisit this issue to provide current information.

## 2) Methods

The yields with and without a winter fishery were examined by conducting long-term projections using modified catch equations. Average weight at age and partial recruitment (PR) vectors were first derived for each fishery (4Vn (January to April) and 4T (May - December)) separately using data for the years 1988-1990 (Chouinard and Sinclair 1989; Chouinard et al. 1990; Hanson et al. 1991). It should be noted that average weights are calculated with a single length-weight relationship derived from data collected during September and therefore differences in average weight-at-age are due to differences in the length-at-age in the commercial samples. Data for the first quarter were used in the calculations for 4Vn. Average weights by year and fishery are presented in Table 1. Partial fishing mortalities (see below) were obtained by multiplying fishing mortalities (F) for the years 1988-1990 (Hanson et al. 1991) by the ratio of the fishery catches to the total catches (4Vs catches in 1990 were excluded).

4Vn				4T			
Age	Year			Age	Year		
	1988	1989	1990		1988	1989	1990
3	0.000	0.000	0.000	3	0.001	0.001	0.003
4	0.030	0.001	0.000	4	0.017	0.016	0.030
5	0.008	0.006	0.003	5	0.061	0.080	0.108
6	0.028	0.016	0.024	6	0.175	0.205	0.192
7	0.029	0.030	0.037	7	0.199	0.239	0.266
8	0.037	0.029	0.055	8	0.244	0.235	0.248
9	0.045	0.035	0.053	9	0.201	0.209	0.192
10	0.070	0.048	0.051	10	0.253	0.254	0.166
11	0.141	0.025	0.046	11	0.390	0.266	0.156
12	0.070	0.058	0.063	12	0.573	0.370	0.129
13	0.006	0.099	0.044	13	0.555	0.359	0.186
14	0.014	0.033	0.065	14	0.216	0.229	0.142
				15	0.285	0.154	0.278
				16	0.249	0.199	0.278

A two-way analysis of variance of these partial F's was then used to derive age and year effects; age effects represent fishing patterns (partial recruitment) while the year effects indicate the changes in fishing mortality from one year to the next.. For the 4Vn fishery, catches of ages 15 and 16 were minimal and therefore F's for these ages were not included in the analyses. The analysis of variance tables are presented below:

For 4Vn:

<i>Source of Variation</i>	<i>SS</i>	<i>df</i>	<i>MS</i>	<i>F</i>	<i>P-value</i>	<i>F crit</i>
Ages	0.017058	11	0.001551	2.349586	0.042414	2.258517
Years	0.000412	2	0.000206	0.311952	0.735201	3.443361
Error	0.01452	22	0.00066			
Total	0.03199	35				

For 4T:

<i>Source of Variation</i>	<i>SS</i>	<i>df</i>	<i>MS</i>	<i>F</i>	<i>P-value</i>	<i>F crit</i>
Ages	0.447666	13	0.034436	4.89667	0.000285	2.119165
Years	0.039309	2	0.019655	2.794841	0.079536	3.36901
Error	0.182845	26	0.007033			
Total	0.669821	41				

The age effects derived from these analyses were then normalized to obtain partial recruitment vectors for each of the two fisheries. The resulting PR vectors (following) indicate that cod are recruited earlier (at a smaller size) to the fishery in 4T than in 4Vn (see also Figure 1). The partial recruitment vector is dome-shaped in 4Vn where the fishery is almost exclusively prosecuted by mobile gears.

Partial recruitment

Age	4Vn	4T
3	0.001	.005
4	0.017	.079
5	0.093	.312
6	0.40	.737
7	0.578	.902
8	0.712	1.000
9	0.807	1.000
10	1.000	1.000
11	1.000	1.000
12	1.000	1.000
13	0.540	1.000
14	0.540	1.000
15	0.540	0.741
16	0.540	0.891

Using these PR for each fishery, a constant recruitment of 10,000 fish, a natural mortality (M) rate of 0.2 and the average weights for the years 1988 - 1990 , stock projections were conducted using two scenarios.

The first simulation represented the status quo with a winter fishery in 4Vn during January to April and a fishery in 4T during the remainder of the year. In this scenario, F for each fishery were allowed to vary so that two conditions would be satisfied: 1) the fully-recruited F for the entire year would be equal to 0.2 and, 2) the catch biomass in 4Vn would amount to 16.3 % of the total catch (1992 allocation from 1992 Groundfish Management Plan). In the second simulation, the fishery was restricted to 4T from May to December and the fully-recruited F was set equal to 0.2. In this case, the only removals from January to April were caused by natural mortality.

### 3) Results

The results (see table below) indicate that the yields from this stock with or without a winter fishery are essentially the same. Although there is no basis to calculate confidence intervals, the yields of the two exploitation strategies are not considered to be significantly different.

	Catch ('000)	Yield (t)	% of <i>status quo</i> yield
<i>Status quo fishery (F = 0.2)</i>	2672	3558	100
<i>4T fishery only (F = 0.2)</i>	2854	3672	103

### 4) Discussion and Conclusion

There are several reasons why the yield of a summer fishery only is not significantly higher than a fishery starting in January. First, observer data tend to indicate that a larger mesh size is used in the winter fishery. Secondly, cod from this stock do not appear to grow before spawning and may lose weight during the winter and spring (K. Schwalm, Dept. of Fisheries and Oceans, P.O. Box 5030, Moncton, N.B. E1C 9B6; pers. comm.). This loss of weight could not be modeled here, however it would apply to both simulations. The spring (April-June) fishery in the southern Gulf of St. Lawrence is prosecuted mainly by mobile gears and in the period 1988-1990 accounted for between 25 and 38% of total landings on the stock (Chouinard and Sinclair 1989; Chouinard et al. 1990; Hanson et al. 1991; 1992). The summer fishery no longer has a large fixed gear component which used to catch larger fish at age. In 1990, fixed gear catches in the southern Gulf of St. Lawrence accounted for about 10% of the landings (Hanson et al. 1992). Finally, at least some of the young cod appear to remain in 4T during the winter (Clay 1991) and consequently more small fish are probably available to the fishery in the summer. All of these observations are consistent with the higher partial recruitment for young ages observed in the fishery conducted in 4T. In the calculations, this higher partial recruitment had the effect of countering the gains in weights at age and therefore did not produce appreciable gains over the current situation.

In general for this stock, increases in yield could likely be obtained by using more selective gears. Although increasing mesh size is one method of improving selectivity, modifications to the mobile gears used such as adding shortened lastage ropes or square mesh panels to facilitate escapement or changing twine size may have a

similar effect. Harvesting when fish are in better condition (i.e., after the growing season) could also increase the yield in terms of biomass. In this case and more generally, the economic dimension will need to be examined closely to determine the effect of a varying supply of fish.
