<sup>1</sup> This series documents the scientific basis for fisheries management advice in Atlantic Canada. As such, it addresses the issues of the day in the time frames required and the Research Documents it contains are not intended as definitive statements on the subjects addressed but rather as progress reports on ongoing investigations.

Research Documents are produced in the official language in which they are provided to the Secretariat by the author.

<sup>1</sup> Cette série documente les bases scientifiques des conseils de gestion des pêches sur la côte atlantique du Canada. Comme telle, elle couvre les problèmes actuels selon les échéanciers voulus et les Documents de recherche qu'elle contient ne doivent pas être considérés comme des énoncés finals sur les sujets traités mais plutôt comme des rapports d'étape sur les études en cours.

Les Documents de recherche sont publiés dans la langue officielle utilisée par les auteurs dans le manuscrit envoyé au secrétariat.

### Abstract

Catches from the stock have ranged from a high of 94,000t in 1966 to a low of no reported catch in 1991. Assessments have not been possible because indices of abundance were lacking. A 1991 fall survey indicated that very few cod were present in the area in spite of reduced fishing effort in recent years. The low catches of recent years may be an indication of low stock levels.

### Résumé

Les prises dans le stock considéré se sont échelonnées entre un sommet de 94 000 t en 1966 et un seuil nul en 1991, année où aucune prise n'a été déclarée. Il n'a pas été possible de procéder à des estimations, faute d'indices d'abondance. Une campagne d'évaluation réalisée en automne 1991 a révélé qu'il y avait peu de morue dans la région, en dépit de la réduction de l'effort de pêche ces dernières années. Les faibles prises récentes sont peut-être une indication du bas niveau du stock.

## INTRODUCTION

The annual catches from this stock range from 94,000 (t) in 1966 to 134 (t) in 1987. (Table 1; Fig. 1) Since 1985 catches have been less than 500 (t) and there was no reported catch in 1991.

A TAC of 20,000 (t) was first introduced in 1974 by STACRES of ICNAF and has remained unchanged since that time. The basis for the advice was first provided in 1973 (ICNAF Res. Doc. 73/106) when a yield per recruit analysis gave an estimate of F max (0.7) which along with recruitment estimates suggested yields (F max) ranging from 20,000 to 40,000 (t) (ICNAF Redbook 1973, p.68). With the prospect of poorer recruitment it was decided to set the TAC at the lower end of the range. At a 1980 meeting of CAFSAC (CAFSAC Subcommittee Report 80/18) additional data were provided to suggest an F0.1 catch consistent with earlier analysis by STACRES (20,000 t.) Catches relative to the TAC'S since 1982 are as follows.

YEAR	1982	1983	1984	1985	1986	1987	1988	1989	1990	1991

## Research vessel surveys

Line transect surveys, for groundfish, were conducted in 2G and 2H in 1978, 1979 and 1981. Random stratified groundfish surveys (Fig. 2-3) were started in 1986, with limited coverage in 2H, and conducted in 2G and 2H in 1987, 1988 and 1991. Abundance and biomass estimates are presented in tables 2-5. The 1978, 1979 and 1981 surveys have been post-stratified. A shrimp survey, in the Hopedale Channel (Fig. 4.) has been conducted since 1979 and cod abundance and biomass estimates from this series are shown in Table 6. (no survey 1989 or 1991)

The results of the groundfish surveys are undoubtedly affected by timing. The influence of the onshore - offshore migration may result in large portions of the stock being outside the survey area, in 1979, 1987 and 1988 as all were conducted during August. The limited 1986 survey in 2H was conducted in late September and had a higher biomass than surveys with much greater coverage conducted in August of 1987 and 1988.

The mean numbers per standard tow for the 1986-1991 random stratified surveys (Table 7.) show substantial year to year variation but the 1981 yearclass is the most abundant in all but 1991.

The shrimp survey series has been conducted during the early July to mid August period. Cod biomass and abundance estimates from these surveys may be influenced by variation in the onshore-offshore migration pattern. However the results indicated a decline in abundance and biomass since 1986.

### Discussion

An analytical assessment of this stock has not been possible in recent years because the required data have been insufficient or entirely lacking. Catch levels have been low and representative sampling data have not always been available. Catch rate data are also limited and no consistent series is available. The survey data are of recent origin and limited value because of problems with spatial coverage and timing.

The low catch rates of recent years may be an indication of low stock level. Reduction of TAC's in other areas and allocations to foreign fleets should have meant an increase in effort. However there has been no reported catch or effort in 1991 and no foreign catch since 1988. The fall 1991 survey indicated that the stock may be at a very low level.
