THE STATUS OF ATLANTIC SALMON STOCKS IN GULF OF ST. LAWRENCE, WESTERN NEWFOUNDLAND AND SOUTHERN LABRADOR, 1992
by

C.C. Mullins and R.A. Jones<br>Science Branch, Gulf Region Department of Fisheries and Oceans P.O. Box 2009<br>Corner Brook, Newfoundland, A2H $6 Z 6$

${ }^{1}$ This series documents the scientific basic for the evaluation of fisheries resources in Atlantic Canada. As such, it addresses the issues of the day in the time frames required and the documents it contains are not intended as definitive statements on the subjects addressed but rather as progress reports on ongoing investigations.

Research documents are produced in the official language in which they are provided to the secretariat.
${ }^{1}$ La présente série documente les bases scientifiques des évaluations des ressources halieutiques sur la côte Atlantique du Canada. Elle traite des problèmes courants selon les échéanciers dictés. Les documents qu'elle contient ne doivent pas être considérés comme des énoncés définitifs sur les sujets traités, mais plutôt comme des rapports d'étape sur les études en cours.

Les documents de recherche sont publiés dans la langue officielle utilisée dans le manuscrit envoyé au secrétariat.

#### Abstract

Recreational quotas introduced in 1992, reduced the potential for increased angling catches as a result of commercial fishery closures. Quotas were reached in all Salmon Fishing Areas before the end of the season. Recreational catches of small salmon were above those in 1991 in all areas, except southern Labrador whereas, catches of large salmon were above those in 1991 and above $95 \%$ confidence limits for the 1984-1989 mean in all areas, including southern Labrador. The proportion of large salmon in western Newfoundland and southern Labrador recreational catches in 1992 was greater than in any previous year.

Returns of small and large salmon to eight index counting facilities were consistent with increased catches in the recreational fishery and the increase in the proportion of large salmon. The distribution of returns to counting facilities by standardized week was also similar to the distribution of catches in the recreational fishery.

Commercial landings of small and large salmon in southern Labrador in 1992 were below 1984-1989 mean cumulative landings to the 1992 closing date. However, only landings of small salmon were below the 95\% confidence limits.

## RÉSUMÉ

Les quotas de pêche récréatives imposés en 1992 ont diminué le risque d'un accroissement des prises des pêcheurs à la ligne par suite de la fermeture de la pêche commerciale. Les quotas ont été atteints dans toutes les zones de pêche du saumon avant la fin de la saison. Les prises récréatives de petit saumon étaient supérieures à celles de 1991 dans toutes les zones, sauf dans le sud du Labrador. Quant aux prises de gros saumon, elles étaient aussi supérieures à celles de 1991 et se situaient au-dessus des limites de confiance de 95\% de la moyenne de 1984-1989 dans la totalité des zones, y compris le sud du Labrador. La proportion de gros saumon parmi les prises récréatives de l'ouest de TerreNeuve et du sud du Labrador était plus grande en 1992 que toutes les années précédents.

Les montaisons de petit et de gros saumon dans huit installations de dénombrement repères étaient conformes à l'augmentation des prises de la pêche récréative et a la plus forte proportion de gros saumon. La répartition des montaisons aux installations de dénombrement par semaine normalisée correspondait aussi à la répartition des prises de la pêche récréative.

À la date de fermeture de la pêche en 1992, les débarquements commerciaux de saumon, gros et petit, dans le sud du Labrador étaient inférieurs aux débarquements moyens cumulés de 1984-1989. Toutefois, seuls les débarquements de petit saumon se situaient en dessous des limites de confiance de $95 \%$.

## INTRODUCTION

The western Newfoundland and southern Labrador, Gulf of St. Lawrence fisheries management area is comprised of seven Statistical Areas (J2, K, L, M, N, O(50), A(01)) and four Salmon Fishing Areas (12, 13, $14(\mathrm{~A})$ and $14(\mathrm{~B})$ ) (Figure 1). Salmon Fishing Area (SFA) 14 (A) (Northern Peninsula) and 14 (B) (southern Labrador) are sub-areas of Salmon Fishing Area 14. These subareas were established in 1991 and reflect the difference in runtiming of Atlantic salmon between to the two areas (Mullins and Jones, 1992).

The status of Atlantic salmon stocks in western Newfoundland and southern Labrador in 1992 is assessed by: 1) comparing commercial and recreational harvests and fishing effort in 1992 with historical harvests and effort in relation to management restrictions; 2) comparing counts of adult salmon returning to index counting facilities with returns in previous years; and 3) examining the effect of management restrictions on fisheries harvests and counting facility returns.

## Commercial Fishery

Major management changes were introduced in 1992 to regulate commercial Atlantic salmon fisheries harvests and permit declining stocks to rebuild. A five year moratorium on commercial fishing was introduced in insular Newfoundland. Commercial fisheries in SFA's 13 and 14(A), as well as in other areas of insular Newfoundland were closed in 1992.

The only commercial fishery for salmon which remained open in 1992 was in southern Labrador, SFA 14(B). The quota for this fishery was set at 13 t , a reduction of 2 t from the 1991 quota (Table 1). The quota monitoring of the southern Labrador fishery was similar to 1991 (Mullins and Jones, 1992). Landings from only the communities in Section 50(a) (Figure 2) applied to the 1992 southern Labrador quota of 13 t . The fishery in Section $50(\mathrm{~b})$ was controlled by the quota for northern Labrador (SFA 2, north of Cape Charles; Figure 1), as in 1991.

The total number of licensed salmon fishermen in the southern Labrador area in 1992 was reduced to 79 from 84 in the previous year. This was the result of a voluntary surrender of some licenses for financial compensation. Fifty-four of the active licenses in 1992 were in Section 50(a), down from 58 in the 1991 season and 25 were in Section $50(\mathrm{~b})$, down from 26 in 1991. Fishermen in Section $50(\mathrm{~b})$ were licensed by the Newfoundland Region.

Commercial gear restrictions in southern Labrador for 1992 were unchanged from those in previous years (Mullins and Jones 1991).

## Recreational Fishery

Major management changes were also introduced in the recreational salmon fishery in 1902. First, Salmon Fishing Area (zonal) angling quotas, in addition to individual river quotas, were introduced in order to achieve maximum spawning potential from salmon not taken in commercial fisheries. These quotas were equivalent to the previous three year (1989-1991) average catch. Second, when either an individual river quota or the Salmon Fishing Area (zonal) quota was reached anglers were permitted to continue to catch and release salmon until the end of the season. Catch and release was permitted primarily to maintain the presence of anglers on the rivers for protection but also to prevent a disruption in the season for outfitters who had booked clients in anticipation of a longer season.

The zonal quotas in western Newfoundland were for small (<63 cm; one-sea-winter) salmon but in southern Labrador, SFA 14(B), the quota was for the total catch of large and small salmon. Large (>=63 cm; multi-sea-winter) salmon as well as small, were permitted to be retained in SFA 14(B). The 1992 quotas and seasons for each SFA as well as river specific quotas and seasons are given in Table 2.

The individual river quotas which were in effect for 1991, remained in place during the 1992 season. One new addition to the list was a 100 fish quota for the Adies Lake segment of the Humber River. This brought to ten, the number of rivers managed by river quota in western Newfoundland. A number of other rivers managed on an individual basis in western Newfoundland, were closed for the entire season as in previous years.

Recreational fishing seasons in western Newfoundland rivers in 1992, were essentially unchanged from seasons since 1985 (Table 1). Season opening and closing dates (Table 2) were changed only to accommodate a Saturday opening and Sunday closing. These seasons, as in previous years, were subject to within-season closures due to low water levels and quota restrictions.

In southern Labrador the 1992 angling season was extended by two weeks from the season in 1991 and one week from seasons since 1974 (Table 1).

The recreational season bag limit of 15 fish , introduced in 1986, and reduced to 10 fish in 1991, was reduced to 8 fish in 1992. The 1992 possession limit of two days catch and the daily bag limit of two fish retained were the same as introduced in 1986. The catch and release limit of 4 fish per day was in effect for the entire season.

## MATERIALS AND METHODS

Atlantic salmon commercial and recreational harvest statistics have been updated from previous reports, therefore, summary tables may differ slightly from those in Mullins and Jones (1992). This difference is most relevant to 1989-1991 commercial harvests because of a delay in receiving purchase slips from some buyers.

Commercial harvests in southern Labrador, as in previous years, were compiled from fish plant sales slips and from Supplementary 'B' slip records of local sales. Supplementary 'B' slips were compiled by Inspection and Conservation and Protection Branch personnel. In 1992, as in 1991 and 1990 (Mullins and Jones 1991), because of weekly quota monitoring, local sales were first compiled weekly, then monthly totals were entered on
Supplementary ' $\mathrm{B}^{\prime}$ slips. Previous to 1990 , local sales had simply been reported monthly, by community, directly onto Supplementary 'B' slips (Jones and Mullins, 1992; Claytor et. al. 1991; Ash and o'Connell 1986).

Commercial landings in the communities of Carroll's Cove, Camp Islands and Cape Charles in Section 50 (b) (Figure 2), were deducted from the quota for northern Labrador (SFA 2, north of Cape Charles) in 1992, as in 1991. These landings were compiled as part of the SFA 14 (B) catch statistics, as in previous years.

Recreational harvest (retained and released fish) statistics in 1992 were compiled from weekly salmon angling reports completed by river guardians throughout the angling season, as in previous years (Mullins and Claytor 1989).

Commercial and recreational fisheries harvests of Atlantic salmon in 1992 were compared with average historical harvests for years in which salmon management plans were similar. Years with similar salmon management were chosen as 1974-1977, 1978-1983 and 1984-1989 (Table 1). Management plans introduced in 1978-1983 were different than those in 1974-1977 because they targetted conservation of large salmon stocks by reducing commercial and recreational seasons. Management plans in 1984-1989 were similar because of similar seasons and because they included closure of the SFA 12 commercial fishery to reduce interception of nonNewfoundland origin salmon. In 1990, to achieve conservation targets in western Newfoundland and southern Labrador rivers, commercial quotas were introduced in SFA's 13 and 14. These quotas were reduced in 1991 (Mullins and Jones, 1992) and again in 1992. Therefore, harvests in the last three years are not comparable with regard to salmon fisheries management restrictions.

Comparisons were also made between 1992 recreational harvests and the previous five year mean.

Counts of migrating salmon at index counting facilities on Pinchgut Brook, North Brook, Hughes Brook, Lomond River, Bound Brook, Torrent River and Western Arm Brook were made by DFO personnel or DFO supervised personnel in 1992. All data were compiled by DFO personnel. The periods of operation of these facilities were similar to previous years:

| SFA | Counting Facility | Date of operation |
| :--- | :--- | :--- |
| 13 |  |  |
| 13 | Pinchgut Brook counting fence | 4-July to 23-September |
| 13 | Nughes Brook counting fence | 26-June to 8-October |
| $14(A)$ | Lomond River fishway fence | 18-June to 8-October |
| $14(A)$ | Bound Brook counting fence | 15-June to 2-November |
| $14(A)$ | Torrent River fishway | 1-June to 26-October |
| $14(A)$ | Western Arm Brook counting fence | 1-July to 23-September |

## RESULTS AND DISCUSSION

## HARVEST SUMMARIES

## Western Newfoundland and Southern Labrador

Not all Atlantic salmon harvests in western Newfoundland and southern Labrador in 1992 were made by licensed fishermen. An estimated 10.3 t of small and large salmon (Table 3) were taken by illegal fishing gear. The largest of these harvests was from cod-traps and illegally set gillnets in Salmon Fishing Area 13. These catches outweighed conservation efforts by anglers in 1992. Assuming and average small and large salmon weight of 2.3 kg , illegal salmon harvests in western Newfoundland and southern Labrador represented approximately 23\% of all recreational (Table 4) and commercial fishing mortality $(16,9 t)$ in the area. By comparison, the number of small salmon which would otherwise have been killed but were caught and released (H\&R) by anglers in 1992 represented only 15\% of the total (Retained $+H \& R$ ) fishing mortality.

Recreational salmon quotas were reached in all western Newfoundland and southern Labrador Salmon Fishing Areas (Table 2) and were followed by catch and release fisheries. Catch and release landings of small salmon (Table 4) comprised $12 \%$ of the total (Retained $+H \& R$ ) catch os small salmon. The largest released catches were on the LaPoile River, SFA 12 and the largest number of retained small salmon was on the Humber River, SFA 13 (Table 5).

The catches of small salmon in the SFA 12,13 and 14 (A) quotas were above catches in 1991 but were no different than the 1984-1989 means for the same period (Figure 4). Had the overall abundance of small salmon increased in 1992 relative to 19841989, catches would be expected to be higher than the 1984-1989 means. The catch of small salmon in the SFA 14 (B), southern Labrador, quota was below the 1984-1989 mean. However, the catch of large salmon was above the 1984-1989 mean, indicating an increase in large salmon abundance in southern Labrador (Figure 4) .

Catches of small salmon dropped off quickly in all Salmon Fishing Areas after the zonal quotas were reached (Figure 5), indicating that catch and release fisheries were not prosecuted to the same extent as retention fisheries. Only in SFA 13, however, were the weekly catches of the catch and release fishery below the 1984-1991 weekly means for the same period (Figure 6).

The catch of large salmon in SFA 14 (B), southern Labrador, had already declined before the zonal quota was reached (Figure 5), resulting in angling exploitation over the entire large salmon run. Only a portion of the small salmon run was exploited by the 1992 quota (Figure 5). The quota in southern Labrador did not result in a reduction in the angling exploitation rate on large salmon. The earlier run-timing of large salmon as well as their greater abundance in 1992 relative to small salmon, resulted in large salmon comprising a greater proportion of the recreational harvest in 1992 compared to previous years (Figure 4) .

Angling effort declined after zonal quotas were reached in all Salmon Fishing Areas. Only in SFA 12 and 13, however, did angling effort decline below the 1984-1991 weekly means in the latter portion of the season (Figure 7). Decreased angling activity, later in the season in these areas may have diminished the deterent to poaching derived from the presence of anglers on the rivers.

The total (Retained $+H \& R$ ) catch of large salmon in western Newfoundland and southern Labrador in 1992 was the highest in the past 19 years (Figure 8) and was above the $95 \%$ confidence limits of the 1984-1989 and 1978-1983 means (Table 6). However, the total (Retained $+H \& R$ ) catch of small salmon for the area, was not above the 1984-1989 or the 1978-1983 mean (Table 6; Figure 6 ). The resultant increase in the proportion of large salmon angled in 1992 was $235 \%$ above the previous five year mean. Western Newfoundland

In the insular Newfoundland portion of the area, the increase in recreational catches of small salmon from those in 1991 and the increase in catches of large salmon from 1991 and long-term means was similar to the whole area (Table 7; Figure 9).

## Salmon Fishing Area 12, Southwest Coast

The SFA 12 recreational quota of 600 small salmon was reached on July 6 (Table 2), nine weeks before the end of the season and four weeks before the zonal quota was caught in any other SFA. Released catches following the quota indicate that had the quota been set at the previous five year (1987-1991) mean of 860 fish (Table 8), the 1992 season would have been one week longer (Table 4).

In SFA 12, 39\% of the angling effort and $42 \%$ of the total catch of small salmon occurred after the zonal quota was reached (Table 4).

The largest catches of small and large salmon in the area were from Lapoile River but the largest amount of angling effort was on Burnt Island River (Table 5).

Recreational catches in 1992 produced the fourth largest angling catch (Retained $+H \& R$ ) of small salmon and the largest catch (H\&R) of large salmon in SFA 12 in the past 19 years (Table 8; Figure 10). This increase in numbers of small and large salmon suggests a positive impact on stocks in this area as a result of the commercial salmon fishery moratorium in other areas.

Catches (Retained $+H \& R$ ) of small salmon were $72 \%$ above those in 1991, however, were only $2 \%$ above the 1984-1989 mean (Figure 10) and within 95\% confidence limits (Table 8), suggesting that the abundance of small salmon did not increase significantly in 1992 relative to most years since 1984.

Recreational catch statistics indicate that only large salmon increased in abundance in 1992 relative to the 1984-1989 mean. Catches (H\&R) of large salmon were $144 \%$ above mean catches in 1984-1989 (Figure 10) and above 95\% confidence limits (Table 8). Large salmon also comprised a greater proportion of the SFA 12 total recreational catch in 1992 than in any year since 1977 (Figure 10). Increased large salmon abundance in this area was, no doubt, influenced by the elimination of the commercial gillnet fisheries in other areas which selectively harvested larger salmon.

Management measures introduced in 1992 produced an increase in total recreational catches relative to 1991 , however, angling effort did not increase (Figure 10). As a result, the catch-per-unit-effort (CPUE) in 1992 was 75\% above that in 1991 (Table 8). The CPUE, however, was only 17\% above the 1984-1989 mean (Table 8).

## Salmon Fishing Area 13, Bay St. George / Bay of Islands

The SFA 13 recreational quota of 5,000 small salmon was taken six weeks before the end of the season (Table 2). Had the quota been set at the previous five year mean of 5,850 fish (Table 9), instead of the previous three year mean, the SFA 13 fishery might have been lengthened by approximately two weeks based on released catch rates in the two weeks after the quota was taken (Table 4).

River quotas were taken on only two of the seven rivers under river quota management prior to the zonal quota being reached (Table 2). Had all rivers been managed under an individual quota the season in which salmon could be retained would have been longer, as a result of quotas being reached later on some rivers.

The largest catches and effort in the area were from the Grand Codroy River in Statistical Area $K$ and the Humber River in Statistical Area L (Table 5). The Humber River had the largest effort and the largest catch of small salmon, however, the Grand Codroy produced the largest number of large salmon.

Catches (Retained $+\mathrm{H} \& \mathrm{R}$ ) of small salmon in 1992 were $15 \%$ above those in 1991 but 5\% below the 1984-1989 mean (Figure 11), suggesting that the number of small salmon angled in 1992 was similar to previous years. In the Statistical Area K portion of SFA 13, however, catches were 9\% below those in 1991 as well as below the 1984-1989 mean (Table 10). The increase in catches of small salmon for SFA 13 was primarily due to the $63 \%$ increase in catches in Statistical Area L (Table 11).

Catches (H\&R) of large salmon in the area, in contrast to small salmon, were $364 \%$ above catches in 1991 and above the 19841989 mean (Figure 11) and 95\% confidence limits (Table 9), suggesting an increase in large salmon abundance in 1992. This increase, as well as being influenced by the closure of the commercial salmon fishery, also follows an increase in small salmon catches in Statistical Area K in 1991 (Mullins and Jones, 1992), suggesting possible increased sea-survival of this yearclass.

The increase in CPUE in 1992 relative to 1991 (Table 9) was the result of increased catches and stable effort in 1992 relative to 1991 (Figure 11).

## Salmon Fishing Area $14(\mathrm{~A})$, Northern Peninsula

The SFA $14(A)$ recreational quota of 3,900 small salmon was reached on August 12, four weeks before the end of the season (Table 2). Of the three individual river quotas on the Northern Peninsula only the Lomond River quota was caught (Table 2).

The largest angling catches in the area were from River of Ponds and Portland Creek (Table 5). River of Ponds produced the largest catch of small salmon and Portland Creek produced the largest catch of large salmon. The large salmon catch on Portland Creek was 71\% above the 1991 catch, and 364\% above the 1984-1989 mean (Table 5). Salmon angling did not begin on Torrent River until August 3, just nine days before the SFA 14 (A) recreational quota was reached. In nine days, 477 small salmon were angled and retained on Torrent River (Table j). The 558 total (Retained + $H \& R$ ) catch for the season on Torrent River was approximately $200 \%$ above the 1984-1989 mean.

Angling catches (Retained $+H \& R$ ) of small salmon in SFA $14(A)$ in 1992 suggest an increase in small abundance from 1991, but there was no change relative to historical levels. Catches were $49 \%$ above those in 1991 (Figure 12), but only 15\% above the 1984-1989 mean (Figure 12) and within 95\% confidence limits (Table 12). The largest catches were in the Statistical Area M (Table 13) portion of the area but the largest increases relative to catches in 1991, were in Statistical Areas N and A(01) (Tables 14,15 ).

Catches (H\&R) of large salmon in the area, were $367 \%$ above the 1984-1989 mean (Figure 12) and above the 95\% confidence limits (Table 12). This increase was due entirely to increased catches of large salmon in Statistical Area M (Table 13). Statistical Area $N$ (Table 14) produced only minimal large salmon catches for the area and no large salmon were angled in Statistical Area A(01) (Table 14).

The large increase in angling catches of large salmon in 1992 relative to 1991 and the 1984-1989 mean, suggests an increase in large salmon abundance relative to those years. The increase in catches of large compared to small salmon also suggests a more positive impact on the abundance of large salmon, as a result of management measures implemented in 1992.

## Salmon Fishing Area $14(B)$, Southern Labrador

The SFA $14(B)$ recreational fishery quota of 1,100 small and large salmon was reached on August 12. The fishery was then permitted to remain open until September 20 for catch and release angling (Table 2).

The early closure did not result in a decrease in angling effort in southern Labrador rivers in 1992 (Figure 13). Total (Retained + H\&R) angling effort was 15\% above the effort in 1991 and equal to the average effort for the 1984-1989 angling seasons, continuing the trend of increasing effort since 1984. Beginning in 1984, angling of large salmon was restricted to catch and release only in insular Newfoundland, but these fish could be retained in southern Labrador.

Catches (Retained $+H \& R$ ) of small salmon in 1992 suggest that the abundance of small salmon was below historical levels in southern Labrador rivers. The catch of small salmon was $20 \%$ below the catch in 1991 and approximately $30 \%$ below the 1984-1989 mean (Table 16; Figure 13). Fifty percent of the cumulative catch was taken one week later ( $\mathrm{p}<.01$ ) in 1992 than in 1984-1991 (Mullins and Jones, 1992), indicating that returns to the rivers had decreased. If stocks had increased in 1992 relative to previous years, $50 \%$ of the catch would be expected to have occurred earlier due to the quota being reached.

Anglers retained (no releases of large salmon were observed) 238 large salmon in southern Labrador in 1992 (Table 4). This was $386 \%$ above the catch in 1991 (Table 16; Figure 13) and 44\% above the 1984-1989 mean, suggesting that the abundance of large salmon improved relative to historic levels.

It is possible, in southern Labrador, that the increase in numbers of large salmon retained relative to small salmon in 1992 was due wholly or partly to 'high-grading'. This practice of releasing small salmon in order to save tags for larger ones has been reported by river guardians on numerous occasions. Increased abundance of large salmon due to commercial quotas in SFA 14 (B) and the closure of commercial fisheries in other areas are also possible influences.

The largest angling catch of small and large salmon in southern Labrador was taken on the Pinware River (Table 5) as in previous years. This river produced 229 of the 238 large salmon angled in 1992.

The commercial salmon harvest in 1992 was the lowest on record (Table 17; Figure 14). The 16.8 t of salmon landed was $50 \%$ below the 1991 landings and 61\% below the 1984-1989 mean ( Table 14).

The low commercial harvest was influenced by the 13 t quota in Section $50(\mathrm{a})$ which was caught on July 6 (standardized week 29). However, because the northern Labrador quota of 120 t was not caught, fishermen in Section 50 (b) continued to fish until the end of the season (October 15). Therefore, the total commercial harvest was expected to be higher than the actual landings. In spite of the longer season in Section $50(\mathrm{~b})$, no salmon landings were reported after week 31 (Figure 15). Section 50 (b) produced only $25 \%$ of the total landings in 1992 (Table 18), compared to 49\% in 1991 (Mullins and Jones, 1992).

The total commercial harvest would not have been greatly influenced by the $6 \%$ reduction in the number of salmon licenses available to be fished in the area in 1992.

The cumulative harvest of small salmon up to week 29, when both the Section $50(\mathrm{a})$ and Section 50 (b) fisheries were open, was 81\% below the 1984-1989 mean and below the 95\% confidence limits (Figure 16). The cumulative harvest of large salmon was $43 \%$ below the 1984-1989 mean up to week 29 but was within the 95\% confidence limits, indicating that the reduction in catches of large salmon was not as severe as for small salmon. Compared to landings since 1984, there was an increase in the proportion of large salmon in the 1992 commercial harvests (Figure 14). Increased abundance of large salmon could have been the result of a reduction in natural or fishing mortality at sea.

The total cumulative harvest of small and large salmon up to week 29 , was approximately $22 \%$ below the cumulative harvests for the same period in 1991 and below all years since 1984 (Figure 16).

## INDEX RIVERS

## Statistical Area R

## Pinchgut Brook

An adult salmon counting fence was operated for the first time in 1992 on Pinchgut Brook, a tributary of Harry's River (Table 2). The fence was located near the mouth of the river, at the point of discharge into a lake flowing into Harry's River. A total of 222 small and 5 large salmon were counted (Table 19). Fifty percent of small salmon were counted prior to the SFA 13 recreational quota being reached on August 1 (Figure 17) and were available to anglers on Pinchgut Brook. The angling catch above the counting fence was 10 small salmon retained and two large salmon released, approximately $10 \%$ of the count at the fence.

Angling catches on this segment of Harry's River averaged 17 small and zero large salmon in 1986-1989 (Mullins et al., 1989; Mullins and Claytor, 1989; Mullins and Jones, prep). Lower catches of small salmon relative to previous years and higher released, catches of large salmon on Pinchgut Brook were consistent with the recreational catch for all of Harry's River in 1992 (Table 5).

## Statistical Area L

## Hughes Brook

Returns of small and large salmon to the counting fence near the mouth of Hughes Brook in 1992 were above the 1984-1989 mean (Table 19). Returns of large salmon were more than three times the 1984-1989 mean.

The 1992 smolt count at Hughes Brook was higher than in any previous year (Table 19), suggesting the potential for higher adult returns in 1993.

## North Brook

Returns of small and large salmon to the counting fence at the mouth of North Brook, a tributary of the Humber River, Deer Lake, in 1992 were above those in 1991. The count of small salmon in 1992 was $152 \%$ greater than in 1991 and the count of large salmon totalled 12 fish in 1992 compared to only one fish in 1991 (Table 19).

Returns of small salmon were $49 \%$ above the 1986 -1989 mean and returns of large salmon were $200 \%$ above the $1986-1989$ mean. This counting fence did not begin operation until 1986.

## Statistical Area M

## Lomond River

Total returns of adult salmon to the fishway on Lomond River in 1992 were the highest ever recorded (Table 20). Compared to mean counts during the last five years (1984-1988) of operation of the fishway, 1992 returns were up $36 \%$. Returns of small salmon were 23\% above the 1984-1988 mean but large salmon returns were 220\% above the 1984-1988 mean.

## Bound Brook

Returns of small salmon to the counting fence on Bound Brook in 1992 were $122 \%$ above those in 1991 and 18\% above the 1984-1989 mean. No large salmon returned to the fence in 1992 (Table 20). The fence did not begin operation until 1986.

## Torrent River

Total returns of adult salmon to the fishway on Torrent River in 1992 were the highest since 1987 (Table 20). Returns of small salmon were $66 \%$ above those in 1991 and $16 \%$ above the 19841989 mean. Returns of large salmon, however, were $132 \%$ above returns in 1991 and $74 \%$ above the 1984-1989 mean.

The run-timing of small salmon returns to the fishway was similar to the timing of recreational catches in the SFA 14 (A) fishery. Counts of small salmon had begun to decline by August 12 (Figure 18), which was consistent with the timing of the decline in angling catches after the zonal quota was reached (Figure 5). The week in which $50 \%$ of the small salmon were counted at the fishway in 1992 (standardized week 30) was the same as the runtiming to the fishway since 1984 (Mullins and Jones, 1992).

## Statistical Area N

## Western Arm Brook

Returns of small salmon to the counting fence on Western Arm Brook in 1992, were 34\% above the 1984-1989 mean (Table 20). Large salmon returns were $700 \%$ above the $1984-1989$ mean. An average of only one large salmon per year had been counted since 1984. Eight large salmon were counted in 1992. This was the largest return of large salmon since 1973 when 30 were counted.

The majority ( $60 \%$ ) of small and large salmon returns to the counting fence occurred prior to the recreational quota in SFA 14(A) being reached (Figure 19) which is consistent with returns to Torrent River fishway in Statistical Area M. The majority of salmon returning to SFA $14(\mathrm{~A})$ in 1992 would have been available to the recreational fishery.

The sea-survival of the salmon smolts counted at Western Arm Brook in 1991 was 3.6\%. The 1992 smolt count at Western Arm Brook (Table 20) was $15 \%$ above the 1991 count; assuming a similar seasurvival to the previous year, returns of adult salmon to the river in 1993 should be about 15\% greater than in 1992.

Table 5. Percentage change in Atlantic salmon catch and effort (Retained $+\mathrm{H} \& \mathrm{R}$ ) in western Newfoundland and southern Labrador rivers in 1992 from those in 1991 and from the 1984-1989 mean. ' + ' indicates an increase and '-'indicates decrease in 1992 catches. H\&R refers to effort and catch after zonal quotas were reached.

* 1984-89 mean values for Lomond River are for 1984-1988.

Footnotes: 1. 1985 and 1986 Western Arm Brook small salmon counts, due to low water conditions which delayed the upstream migration, are adjusted values based on the ratio of mark to unmarked at the counting fence (Claytor and Mullins, 1988). The actual for these years counts were 168 and 252 , respectively.
2. 1988 Western Arm Brook upstream counts determined from kelt counts in 1986 and 1989.
3. 1989 Western Arm Brook upstream count based on recapture ratio of 1:0.1 marked to unmarked kelts in 1990.
4. 1990 Western Arm Brook upstream count based on recapture ratio of 1:2.6 marked to unmarked kelts in 1991.
5. 1991 Torrent River small and large in July was the 1991 total count multiplied by the \% s mall and large for July in 1985-1990.

Figure 1. Boundaries of Salmon Fishing Areas (SFA), Statistical Areas (Capital Letters), Statistical Sections (Numbers), for Western Newfoundland and Southern Labrador, Gulf Region.

Figure 2. Location of communities within Coastal Areas in Western Newfoundland and Southern Labrador, Gulf Region. For community numbers see Table 2.

Fig. 3. Location of salmon rivers in Western Newfoundland and Labrador. Refer to Table 2 for map index.

Figure 4. Cumulative recreational catch of small and large salmon in 1984-1992 up to the closing date in 1992. Horizontal lines represent the 1984-1989 means.

 Large ( $>=63 \mathrm{~cm}$ )

 week quota was reached.

Figure 6. Comparison of weekly catches of small and large salmon in 1992 with the 1984-1989 weekly mean. Arrows indicate week quota was reached.

Figure 7. Comparison of angling effort in 1992 with the 1984-1989 mean by standardized week. Arrows indicate week quota was reached.
