¹This series documents the scientific basis for the evaluation of fisheries resources in Atlantic Canada. As such, it addresses the issues of the day in the time frames required and the documents it contains are not intended as definitive statements on the subjects addressed but rather as progress reports on ongoing investigations.

Research documents are produced in the official language in which they are provided to the secretariat.

¹La présente série documente les bases scientifiques des évaluations des ressources halieutiques sur la côte atlantique du Canada. Elle traite des problèmes courants selon les échéanciers dictés. Les documents qu'elle contient ne doivent pas être considérés comme des énoncés définitifs sur les sujets traités, mais plutôt comme des rapports d'étape sur les études en cours.

Les Documents de recherche sont publiés dans la langue officielle utilisée dans le manuscrit envoyé au secrétariat.

Abstract

Catches fluctuated between 3000 t and 4500 t from 1980 to 1991 and decreased in 1992 to 2300 t. Commercial catch rates varied widely during the 1980s reaching very high values in 1986 and 1989 perhaps reflecting increased concentrations of fish rather than higher stock sizes. Biomass estimates from research surveys decreased from about 40,000-45,000 t in the early 1980s to about 2500 t in 1992. The geographical distributions of witch in the surveys changed suddenly in 1986 after the 1985 fall survey. The area of distribution has gradually decreased since. The fishery in recent years has been prosecuted in depths deeper than those covered by the survey.

Résumé

Les prises ont fluctué entre 3 000 et 4 500 t de 1980 à 1991 et ont chuté à 2 300 t en 1992. Les taux de prises commerciales ont considérablement varié au cours des années 1980, pour atteindre des valeurs très hautes en 1986 et 1987, signes peut-être de concentrations accrues de poisson plutôt que d'une augmentation du stock. Les estimations de biomasse établies d'après les relevés de recherche sont passées d'environ 40 000-45 000 t au début des années 1980 à quelque 2 500 t en 1992. La distribution géographique de la plie dans les relevés a changé brusquement en 1986, après le relevé d'automne de 1985. La zone de distribution a progressivement diminué depuis. Ces dernières années, la pêche a eu lieu dans des eaux plus profondes que celles visées par le relevé.

Nominal Catches

The commercial fishery began for witch in this area in the early 1960s and increased steadily from about 51,000 t in 1963 to a peak of over 24,000 t in 1973 (Table 1; Fig. 1). Catches declined as rapidly as they began to 2800 t in 1980 and subsequently fluctuated between 3000 t and 4500 t to 1991. The catch in 1992 was just 2300 t, the lowest since 1964. Up until the late 1980s, the fishery was prosecuted by Poland, USSR, and Canada; however, in recent years, the fishery has been conducted mainly by Canada although significant catches are taken by EEC (Portugal) as part of an unregulated fishery in the NAFO Regulatory area of Division 3L. Most of the catch has been caught traditionally in Division 3K (Table 2; Fig. 1) except since 1986 where the catch in Division 3L has become significant due to this fishery in the NAFO Regulatory area of Division 3L. None of Division 3K extends outside the Canadian 200-mile zone, but there is a natural extension of the slope area beyond 200 miles in Division 3L.

Since 1988, there has been a very successful offshore Canadian fishery on spawning concentrations in the deep slopes of Division 3K especially in depths beyond 700 meters. Between 1988 and 1993, however, the area fished has become increasing smaller and substantially deeper. The fishery in the winter of 1993 was very poor according to log reports, and the only economic catch rates occurred in depths greater than 1400 meters which were at the limits of most domestic trawler capabilities. Catches quickly declined until they became too low for economic viability and the fishery stopped. It can be anticipated that the nominal catch in 1993 will likely be the lowest since the fishery began.

Catch and Effort

Little directed effort data are available for witch; however, for illustrative purposes a multiplicative analysis was conducted on information since 1973 where directed catch was assumed to be a catch comprised of more than 50 % witch. The results are shown in Table 3 and Figure 2. The trends in catch rates are very difficult to interpret with any degree of confidence particularly in the late 1980s where catch rates fluctuated wildly. It is possible that the high points may be more a reflection of fish concentrating in deep areas at high density levels. It may further be hypothesized that declines in recent years are a reasonably true reflection of reduced biomass especially when it is known that the spatial distribution of the effort has been systematically reducing over time.

Commercial Catch at Age

Catch at age data from the commercial fishery are shown in Table 4 for the years 1981-92. There has clearly been a reduction in the number of age groups comprising the population with a maximum age of 17 in 1981 and 14 since about 1986. In fact, in the early to mid-1970s, there were fish in the population up to age 26 years old. Nevertheless, the age structure has been fairly consistent since 1985. While no stock recruitment relationship for this stock has ever been investigated, it is worth noting that by truncating more than 10 age groups off the older portion of the stock there may very well have been a reduction in the reproductive potential of the resource and subsequent recruitment.

Biological Surveys

Stratified-random surveys have been conducted in the fall in Div. 2J, 3K, and 3L since 1977, 1978, and 1981 respectively. In the past, for years when surveys were incomplete, biomass estimates for missing strata were obtained using multiplicative regression analyses. However, with more complete coverage in recent years and significant changes in distribution (which violates the assumptions of the model) values for missing strata were not estimated.

1) Biomass estimates:

For Division 2J, biomass estimates ranged from as high as 4100 t in 1986 to a low of just over

500 t in 1992 (Tables 5 and 6). In Division 3K, during 1979-85, there was a period of relative stability where most annual biomass estimates were over 30,000 t (Tables 7 and 8). Since that time, catches have declined considerably to 935 t in 1992 the lowest in the time series. For Division 3L, biomass estimates varied generally between 6000 t and 7000 t from 1981-88 but declined rapidly since then to a low of just under 1500 t in 1992 (Tables 9 and 10).

For the three divisions combined (Fig. 3), it can be seen that with the exception of 1990 there has been a very steady and systematic decline from about 1984 through 1992 with the estimate of about 3000 t in 1992 now lower than the existing TAC of 4000 t.

2) Biomass by Depth:

Estimates of biomass by depth are presented by division in Figures 4, 5, and 6 respectively for Divisions 2J, 3K, and 3L. It is clearly seen that, for all divisions in the earlier years of higher abundance, the biomass is distributed in depths generally less than 500 meters; however, for more recent times, particularly in the 1990s, most abundance is found in depths greater than 500 meters. Based upon these observations and the knowledge that the commercial fishery operates in much deeper zones, it is also evident that the depth constraints of the survey design is restrictive in measuring the complete biomass of this species more particularly in recent years.

3) Estimates of abundance at age:

Estimates of abundance at age from fall surveys are presented in Tables 11, 12, and 13 for Divisions 2J, 3K, and 3L respectively. In all cases, there were evidently older fish in the populations in the earlier period with a broader age range although it was not as explicit as in the commercial catch at age data. Age structure has been much more stable over the last 10 years or so although the actual abundance at age has been declining rapidly in the recent period.

Distribution

Annual distribution plots of witch flounder catches from research vessel surveys in Divisions 2J, 3K, and 3L during 1978-92 are presented in Figures 7-10 respectively. From the period 1978-85 the pattern of distribution is fairly consistent with the dominant division being Division 3K as expected. In fact, the distribution in those years is also consistent with distribution patterns previously published on data collected during the 1950s and 1960s. Between 1985 and 1986, however, there was a substantial change in the pattern culminated by a considerable reduction in biomass. The high abundance of witch usually associated with the deep channels on the western side of Funk Island Bank virtually disappeared. Throughout the late 1980s, area of distribution continued to shrink towards the southeast portion of Division 3K; and by 1990 it became clear that the only fish left appeared to be concentrated along the very deep slope area. Even more disturbing is that by 1992 the only area where witch flounder showed up in the survey area was in the deep slope area of the Sackville Spur ("Nose" of the Grand Bank) outside the Canadian 200-mile zone.

Conclusion

From the information presented here, it is quite clear that this stock has been reduced to levels far below anything observed in the past. It would seem also that, for the period when reductions were most dramatic, it is unlikely that fishing intensity would have been the most significant factor. On the other hand, having observed the shrinking area of distribution in recent years coupled with the fact that fishing was most intense in this area during prespawning aggregations, it is probable that fishing may have accelerated the decline over the last couple of years. It may be argued that because the fishery has recently been prosecuted well beyond depths occupied by the surveys, biomass estimates may be biased downwards. Nevertheless, since fishing has taken place in a very restricted area and in 1993 was a virtual failure, it is difficult to accept that this stock is not at a dangerously low level.
