'This series documents the scientific basis for the evaluation of fisheries resources in Atlantic Canada. As such, it addresses the issues of the day in the time frames required and the documents it contains are not intended as definitive statements on the subjects addressed but rather as progress reports on ongoing investigations.

Research documents are produced in the official language in which they are provided to the secretariat.

'La présente série documente les bases scientifiques des évaluations des ressources halieutiques sur la côte atlantique du Canada. Elle traite des problèmes courants selon les échéanciers dictés. Les documents qu'elle contient ne doivent pas être considérés comme des énoncés définitifs sur les sujets traités, mais plutôt comme des rapports d'étape sur les études en cours.

Les Documents de recherche sont publiés dans la langue officielle utilisée dans le manuscrit envoyé au secrétariat.

Abstract

Catches from this stock have generally been about 1000 tons annually since 1979. Biomass has been estimated from surveys since 1976 and have generally been between 3000 tons and 6000 tons during the 1980s with no identifiable trend. In February 1993, biomass was estimated at 2000 tons compared to 3000 tons in April 1993. Ages ranged as high as 22 years old in the mid-1970s but was reduced to a maximum of 14 years old by 1980. Age distribution has remained relatively stable since that time.

Résumé

Les prises annuelles en provenance de ce stock ont été de l'ordre de 1 000 t depuis 1979. La biomasse, fondée sur des relevés de recherche depuis 1976, s'est généralement située entre 3 000 et 6 000 tonnes dans les années 1980 et ne semblait pas suivre une tendance discernable. On l'estimait à 2 000 t en février 1993 et à 3 000 t en avril 1993. La fourchette d'âges allait jusqu'à 22 ans au milieu des années 1970; en 1980, elle était tombée à un maximum de 14 ans. La distribution des âges est restée relativement stable depuis lors.

Description of the Fishery

The catches of witch flounder in NAFO Subdivision 3Ps were about 1000 tons annually during the 1960s. Catches then increased to over 4000 tons in 1967-69, then declined slowly to former levels in the late 1970s. During the last 10 years, catches have ranged from as low as 300 tons in 1983 to as high as 1300 tons in 1986 (Fig. 1). However, with a TAC of 1000 tons in place since 1988, the average catch since 1989 has been about equal to the TAC. During the 1980s, the catch was primarily a by-catch of other groundfish fisheries; however, in recent years with the severe declines in major groundfish resources (flatfish species in particular) certain sectors of the fishing industry have become much more dependent on stocks such as these. This is especially true when catch rates are economically viable and market prices and demands are high.

Catches from this stock have been taken mainly by Canadian trawlers fishing offshore on St. Pierre Bank while there are some catches taken by small Scottish seiners and gillnetters fishing in Fortune Bay off the southcoast of Newfoundland. There are also some catches taken by French fishermen off St. Pierre and Miquelon although these catches usually account for small amounts.

Biological Surveys

Stratified-random research vessel surveys have been conducted by Canada in wintertime on St. Pierre Bank since the early 1970s; however, only since about 1976 has coverage been relatively complete, at least to a depth of 300 fathoms. The results of these surveys for witch flounder are presented in Tables 1 and 2. Biomass estimates have been highly variable over the past 15 years or so, fluctuating between 2000 and 6000 tons showing little in the way of trends. It has been suggested in the past that the reason for this is that the main depths where witch flounder are not surveyed by the research vessels. While two recent surveys in 1993 are within the range of past biomass estimates, it is known that a quite successful fishery occurred in deep water beyond the range of the surveys which would lend support to this hypothesis. On the other hand, it is also true that the fishery concentrates within a relatively small area on a prespawning concentration of probably high density. While commercial catch rates may appear quite viable in a small area, it is necessary to be cautious and not misinterpret as a real indication of a healthy stock.

When survey indices are plotted by depth zone (Fig. 2), it can be observed that during the late 1970s and early 1980s there were considerable levels of the existing biomass in depths less than 100 fathoms whereas during the 1980s there were none.

Catch at Age

Abundance estimates at age from research vessel surveys are presented in Table 3. In the mid-1970s, ages ranged as high as 22 years old; however, this was reduced to a maximum of 14 years old by 1980. The age structure has remained relatively stable since that time to the present although the abundance indices have shown considerable variation on an annual basis as indicated earlier.

Conclusion

Long-term prospects for this stock are uncertain. The 1993 fishery was considered highly successful; however, it was prosecuted on a very densely aggregated pre-spawning concentration and may not be representative of stock abundance.
