¹This series documents the scientific basic for the evaluation of fisheries resources in Atlantic Canada. As such, it addresses the issues of the day in the time frames required and the documents it contains are not intended as definitive statements on the subjects addressed but rather as progress reports on ongoing investigations.

Research documents are produced in the official language in which they are provided to the secretariat.

¹La présente série documente les bases scientifiques des évaluations des ressources halieutiques sur la côte Atlantique du Canada. Elle traite des problèmes courants selon les échéanciers dictés. Les documents qu'elle contient ne doivent pas être considérés comme des énoncés définitifs sur les sujets traités, mais plutôt comme des rapports d'étape sur les études en cours.

Les documents de recherche sont publiés dans la langue officielle utilisée dans le manuscrit envoyé au secrétariat.

ABSTRACT

The fall distribution and acoustic backscatter of herring in NAFO Divisions 4T and 4Vn obtained from fall acoustic surveys for the years 1990, 1991 and 1992 indicate that the Chaleur Bay area is the main area of concentration for herring in October and early November. Most herring schools were found in the East Miscou, Shigawake and Maisonneuve strata of Chaleurs Bay in 1991 and 1992, while the 1990 backscatter was mostly recorded in the western part of the bay. The Cape Breton area accounted for 22% of the backscatter in 1992, and 10% or less in 1991 and 1990; the main area of concentration being Aspy Bay strata. Biomass estimates indicate that 1990 had the highest value of the three years, while the proportion of transects with backscatter present and the percentage of mileage covered with backscatter recorded both reveal a higher value for 1992, followed closely by 1991. Fall spawners represented 81.6% of the 1992 total backscatter, 74.7% in 1991 and 49.1% in 1990. The 1987 year class accounts for 36% of these fall spawners in 1991 and 29% in 1992. The 1990 survey had large amounts of juvenile herring in the trawl sets, which were mostly spring spawners; juveniles of ages 1 and 2 comprised 46% of the total backscatter. Temperatures in all areas ranged between 0 and 12°C for both the 1991 and 1992 surveys. In general, stronger haloclines and thermoclines were observed in the inshore strata.

RESUME

La distribution géographique et la diffusion acoustique des bancs de harengs détectés durant les relevés acoustiques de 1990, 1991 et 1992, dans les divisions 4T et 4Vn de l'OPANO, indiquent que la baie des Chaleurs est la principale région de concentration du hareng en octobre et début novembre. En 1991 et 1992, la plupart des bancs de hareng furent détectés dans les strates de Miscou Est, Shigawake et Maisonneuve, tandis qu'en 1990, 78% de la diffusion acoustique fut détectée dans la partie ouest de la baie. Dans la région du Cap Breton, 22% de la diffusion acoustique y fut détectée en 1992, et seulement 10% ou moins en 1991 et 1990; la strate principale étant celle de Aspy Bay. L'estimation de la biomasse d'après l'intensité de la diffusion acoustique indique que l'année 1990 est la plus élevée. D'autres indices, tels que la proportion de transects avec de la diffusion acoustique détectée et le pourcentage de la distance totale couverte sur laquelle il y avait de la diffusion acoustique présente, indiquent que les valeurs les plus élevées étaient en 1992, suivie de près par 1991. Les géniteurs d'automne représentaient 81% de la diffusion acoustique totale en 1992, 74.7% en 1991 et 49.1% en 1990. De ceux-ci, la classe d'âge de 1987 comptait pour 36% du total en 1991 et 29% en 1992. En 1990, une bonne proportion des échantillons étaient composés de harengs juvéniles qui représentaient 46% de la diffusion acoustique totale; la plupart étant des géniteurs de printemps âgés de 1 et 2 ans. La température des masses d'eau variait entre 0 et 12°C pour les années 1991 et 1992. En général, les haloclines et thermoclines les plus prononcées se situaient dans les strates côtières.

INTRODUCTION

From 1984 to 1989, Gulf Region conducted acoustic surveys of late fall concentration of herring in the southern Gulf using the ECOLOG system (Shotton 1986, Shotton et al. 1987 a and b, Cairns et al. 1988 and 1989, Cairns and Wright 1990). Since 1990, a Simrad EY200 echo sounder with a single-beam 120 KHz transducer has been used.

This paper provides the fall distribution and acoustic backscatter of herring in NAFO Divisions 4T and 4Vn for the years 1990 to 1992. The 1990 acoustic survey was held mostly in November, while the 1991 and 1992 surveys were in October. Survey effort was concentrated in the Chaleurs Bay and Cape Breton areas, where NAFO division 4T herring congregate in the fall.

METHODS

SURVEY DESIGN, AREA AND SAMPLING

Acoustic surveys were conducted according to a stratified random design, using random parallel transects within strata. Transect lines were selected from a series of points spaced 200 meters apart on the seaward boundary of a stratum. Perpendicular lines were drawn from the selected points to approximately the 10 fathom depth line inshore or to the opposite boundary line in the case of offshore strata. Strata and their boundaries were those used in 1989 (Cairns and Wright 1990) plus added strata (Figure 1, Table 5).

Survey time among strata was allocated so that the density of coverage varied with the expected herring biomass. Each year, available survey time per stratum was thus directly proportional to the mean backscatter density recorded in past surveys plus the proportion of seiner set sites per stratum. To ensure that all areas were adequately covered, we adjusted the initial time allotments so that a minimum of 4 transects were selected in each stratum. However, the East Miscou stratum, being much larger than all others, is allotted a fixed time for coverage depending on the number of sea days available.

Whenever possible, coverage of inshore strata, where most herring schools are found, was done at night when fishing for species identification and biological samples was possible. In 1991 and 1992, a CTD (conductivity and temperature versus depth) probe was cast at preselected stations, to obtain temperature and salinity profiles of the area surveyed.

1992 Survey

Acoustic transects were run from October 1 to 22nd on the research vessel E.E. Prince. Transects were run 24 hours a day at an average speed of 8 knots. Available survey time per stratum was allocated so that the density of coverage was directly proportional to the mean backscatter density recorded for the years 1985 to 1989 and 1991, plus the 1989, 1990 and 1991 proportion of seiner set sites per stratum. The sequence of coverage was from east to west in the inner Chaleurs Bay, followed by the Gaspe area, East Miscou, eastern PEI, northwest and northeast Cape Breton, and Sydney Bight (Figures 2 and 3). Overall, more than 95% of planned transects were covered.

1991 Survey

Acoustic transects were run from October 10 to 24 on the research vessel Alfred Needler. Transects were run 24 hours a day. Available survey time per stratum was allocated so that the density of coverage was directly proportional to the mean backscatter density recorded for the years 1985 to 1989, plus the 1989 and 1990 proportion of seiner set sites per stratum. The sequence of coverage was East Miscou, followed by the Gaspe area, east to west in the inner Chaleurs Bay, northwest and northeast Cape Breton, and Sydney Bight (Figures 4 and 5).

On the third transect of the survey (Oct. 10), towed body and cable got snagged in submerged gear line and signal was lost. Damage was done to the new cable sheath and splicing was done. On Oct. 17, the transceiver's motherboard had to be replaced. Further cable problems occurred on Oct. 18 to 20 which forced us to reduce ship speed.

1990 Survey

Acoustic transects were run from October 26 to November 8 on the research vessel Alfred Needler. Transects were run 24 hours a day. Available survey time per stratum was allocated so that the density of coverage was directly proportional to the mean backscatter density recorded for the years 1985 to 1989. The sequence of coverage was East Miscou, followed by the Gaspe area, east to west in the inner Chaleurs Bay, northwest and northeast Cape Breton, and Sydney Bight (Figures 6 and 7). Cable problems also occurred early in the survey and splicing was done on October 26 and 29.

Biological Sampling

Fishing for species identification and biological samples were only possible at night using a midwater trawl. The Alfred Needler used an IYGPT trawl in 1990 and 1991, while on the E.E. Prince, an Engles 400 midwater trawl was used in 1992. Wherever large concentrations of acoustic backscatter were detected in a particular stratum, a set was cast. The total catch of herring and other species was estimated, and a sample of up to 350 herring were measured. Also, a subsample of 3 herring per 0.5 cm group was kept and frozen for detailed laboratory analysis.

Temperature and Salinity

A total of 83 CTD profiles were taken during the 1992 survey. In 1991, 68 casts were done. The instrument used was a Seabird SBE 9 Seacat Profiler. The CTD profiles were taken at least once per stratum, and in the majority of cases, at least once at both boundaries of the stratum. In order to summarize the data, the strata were divided into four areas: the Gaspe Peninsula, the eastern end of the Bay des Chaleurs, the western end of the Bay des Chaleurs and Cape Breton.

ACOUSTIC DATA ANALYSIS

Equipment

The acoustic equipment consisted of a Simrad 120-25-E single beam transducer. The echo sounder used was a Simrad EY200. The signal received by the echosounder was digitized using a Femto model J9001 dual channel digitizer.

The SIMRAD EY200 transceiver used on the acoustic survey does not have a constant ping rate, but the digitizer samples at a constant frequency. It was found that the sample size per ping vary (C.V. of up to 30 %). Area Scattering coefficient (S_a) are not calculated for each ping but averaged over a larger integration interval. The number of pings per unit of integration was found to have a much smaller C.V. (3 % or less). Further analysis has shown that there is no correlation ($r^2 < 0.1$) between the number of samples per integration interval and the ping rate. Hence, the variable ping rate does not bias the data.

Calibration

Two methods were used to calibrate the acoustic equipment. The first method consisted of using a dummy load on the transceiver. This calibration was unsuccessful due to loading of the EY200 on the calibration circuit. The second method of calibration was to use a Biosonics 120 kHz calibration ball. This method is combined to TVG calibrations for the various transceiver settings used during the survey. The calibration data obtained showed a combined fixed and TVG gain of 16.887 dB at Gain 4 and Attenuation 0.

The calibration parameters used were:

Source level and Receiver Sensitivity: 31.99 dB

TVG: 20 log R

Equivalent Ideal Beam Angle: -17.5 dB

Pulse Length: 1 m sec

Frequency: 120 kHz

Sampling Threshold: 0.25 mV

Calibrations constants for 1991 and 1990 were calculated from 1992 calibrations. During the 1991 cruise, and again after the cruise, the transceiver was repaired and the motherboard was changed. These repairs may have caused a variation in the transceiver fixed gain. An attempt to quantify the variation caused by the on cruise motherboard change, by checking the bottom signatures before and after the change, showed that the gain difference may be as high as 5.3 dB. However, unknown factors such as the time at which the original motherboard went out of alignment, towed body position and effects of the second motherboard change make it impossible to attribute these changes solely to the on cruise motherboard change. Therefore, we assumed that no internal gain changes in the EY200 occurred from 1990 to 1992. In 1990, a TVG of 40 log R was used on the EY200. The calibration was compensated for this by adjusting the source level accordingly.

Data Editing and Processing

All data acquisition, editing and processing were done using the Femto Model 9001 Hydroacoustic Data Processing System (HDPS). To select acoustic targets attributed to herring, verification was made by fishing whenever possible. Most of the major acoustic concentrations were identified in this manner. (Tables 5 to 7). The visual configuration and distribution of positively identified herring acoustic targets, confirmed by many trawl sets over the years surveyed, plus acoustic logbook observations, helped in the selection process when fishing was not possible. Calculation of mean and variance of acoustic backscatter and biomass estimates follow procedures outlined by O'Boyle and Atkinson (1989) (Appendix 1).

The proportion of transects with recorded backscatter was determined. Also, an estimate of the total mileage surveyed and the proportion thereof which had backscatter recorded was done, based on the charted maps of backscatter distribution.

Target Strength

Foote's (1987) formula was used to calculate target strength based on length and weight of sampled fish (Appendix 1). Mean length were derived from the length frequency samples, while the weight-length regression was obtained from the detail samples. One single target strength per year was calculated for the Cape Breton strata, as fish size distribution was fairly homogenous throughout the area. In Chaleurs Bay, strata with predominantly juvenile herring present were identified and assigned a different target strength than the strata with adult herring (Table 1).

Foote's (1987) formula was derived from nighttime measurements on in situ herring. Experimental evidence has shown that target strength is higher during the day than at night (MacLennan and Simmonds, 1992). Experiments with caged fish have shown that the diurnal change in target strength correlates well with the tilt angle of the body. This is probably caused by some change in fish behaviour associated with light level. Buerkle (1990) noted that fish orient at different tilt angles during the day than at night and suggests that applying nighttime target strengths to daytime fish orientations likely overestimates biomass.

Since the difference between nighttime and daytime target strengths could not be quantified, the data summary tables were divided into day and night time periods (night = 1900 to 0700 HR) and an estimate of the percentage of backscatter recorded during either time periods is included.

RESULTS

DISTRIBUTION AND BACKSCATTERING OF ACOUSTIC TARGETS

The distribution of herring encountered during surveys in the Chaleurs Bay and Cape Breton areas for the years 1992, 1991 and 1990 are mapped in Figures 2 to 7. Backscatter and biomass estimates per transect for each year and both areas are presented in Tables 2 to 4, subtables a, b, c and d. The total backscatter and biomass estimates per strata for these same areas are found in Tables 5 to 7.

1992 Survey (Oct. 1-22)

The 1992 acoustic survey backscatter per transect by area and time period is detailed in Tables 2a) Chaleur nighttime, 2b) Chaleur daytime, 2c) Cape Breton nighttime and 2d) Cape Breton daytime. The total per strata values (nighttime plus daytime) are summarized in Table 5, with the visual distribution in Figures 2 and 3.

Close to 45% of the total 1992 backscatter was recorded in the East Miscou stratum (number 23). Another 25% of the total was located in the Chaleur inshore strata, with the highest concentrations found in the northern strata of Grande-Riviere and Shigawake, followed by the southern stratum of Maisonneuve, all of which were extensively covered and have comparatively low variance values.

The Cape Breton area accounted for 22% of total backscatter, almost entirely found inshore, with Aspy Bay and Neil Harbour strata to the northwest having the highest values.

1991 Survey (Oct. 10-24)

The 1991 acoustic survey backscatter per transect by area and time period is detailed in Tables 3a) Chaleur nighttime, 3b) Chaleur daytime, 3c) Cape Breton nighttime and 3d) Cape Breton daytime. The total per strata values (nighttime plus daytime) are summarized in Table 6, with the visual distribution in Figures 4 and 5.

A large proportion, 50% of the total backscatter, was recorded in the east Miscou stratum in 1991. The Chaleur inshore strata accounted for another 37% of the total, once again with the northern strata of Shigawake having a high value, followed by the southern strata of Maisonneuve.

In Cape Breton, 10% of the total backscatter was recorded, concentrated mainly in the Aspy Bay stratum. No offshore strata were surveyed in 1991.

1990 Survey (Oct. 26 -Nov. 8)

The 1990 acoustic survey backscatter per transect by area and time period is detailed in Tables 4a) Chaleur nighttime, 4b) Chaleur daytime, 4c) Cape Breton nighttime and 4d) Cape Breton daytime. The total per strata values (nighttime plus daytime) are summarized in Table 7, with the visual distribution in Figures 6 and 7.

Most of the 1990 backscatter was recorded in the western part of Chaleur Bay, with 58% of the backscatter in the Carlisle offshore stratum. The three sets which were made there consisted mostly of juvenile herring. Together with the New Richmond and Richmond Offshore strata, also in the western part of the bay, these three strata accounted for 78% of the 1990 total backscatter.

The remaining 22% of backscatter recorded is dispersed. The Cape Breton strata of New Waterford and Aspy Bay accounted for 10% of the total backscatter.

Total Backscatter and Biomass Estimates

Total acoustic backscattering and biomass estimates, using Foote's (1987) formula for target strength, in the Southern Gulf from 1988 to 1992 are presented in Table 8. The current randomly selected parallel transects sampling design was initiated in 1988. Included in Table 8, for the years 1990 to 1992, are the proportions of transects surveyed during nighttime (1900 - 0700 HR) and the proportion of backscatter and biomass which was recorded at night.

The 1990 survey has the highest backscatter and biomass values, with 78% of the total backscatter from the western part of Chaleur Bay, consisting mostly of juvenile herring. If the proportion of smelt present in sets was subtracted from estimated biomass, the 1990 biomass estimate would decrease by 193990 tons.

In 1991 and 1992, the Chaleur Bay offshore strata had the highest proportion of total backscatter and biomass, due to the East Miscou stratum which accounted for most of this total. If the proportion of smelt present in sets was subtracted from estimated biomass, the 1992 biomass estimate would decrease by 6916 tons.

The proportion of backscatter and biomass detected at night was 75% in 1991 and 1992, and 80% in 1990. The highest number of transects surveyed was in 1992. This considerably reduced the coefficient of variation values, especially in the inshore strata of both Chaleur Bay and Cape Breton.

Proportion of Transects with Backscatter

The number of total transects per stratum and the proportion of transects with backscatter from the 1988 to 1992 herring acoustic cruises can be found in Table 9.

The 1992 survey had the highest proportion of transects with backscatter overall (0.67) as well as for each of the areas; Chaleur inshore (0.73), Chaleur offshore (0.64) and Cape Breton inshore (0.82). 1991 shows the second highest proportions with an overall value of 0.46, followed by the year 1988 (0.25). In contrast, 1990 showed the lowest values, with an overall proportion of 0.22, and for Chaleur inshore (0.13), offshore (0.16). The 1989 survey was only partially completed and is not considered here.

The area showing annually the highest proportion of transects with backscatter is Cape Breton inshore, although the number of transects surveyed in this area is lower than the Chaleur Bay inshore and offshore areas.

Percentage of Transect Length with Backscatter

Table 10 is a resume of total transect length covered per strata, together with the total transect length showing herring backscatter, and the percentage of transect length covered with backscatter, for the years 1988 to 1992.

The 1991 and 1992 surveys have the highest percentage length of transect with backscatter. Overall, 1991 had 16.8%, with the Chaleur area at 17.1% and the Cape Breton area at 16.7%. In 1992, the overall value was 13.6%, with Chaleur having 13.1% and Cape Breton 16.8%. In comparison, the 1990 survey had the lowest percentages of these three years, with an overall value of 8.8%, with Chaleur area at 6.1% and Cape Breton at 15.3%.

Annually, the area showing the highest percentage length of transect with backscatter is Cape Breton inshore.

TRAWL SETS, SAMPLE COMPOSITION AND CTD PROFILES

Lengths, weights and spawning affinity of herring acoustic cruise samples from 1990 to 1992 are summarized in Table 1.

1992 Survey (Oct 1 - 22)

The 1992 survey set locations can be found on Figures 2 and 3, plus per strata sets in Table 5. Length frequency distributions of herring samples are shown in Figures 8a and 8b.

Mostly adult herring were found in sets both in Chaleur Bay and the Cape Breton area. Juvenile herring were found in New Carlisle and Anse a Beaufils strata sets. Over 90% smelt were present in sets from New Richmond inshore and offshore strata at the western end of Chaleur Bay. The Cape Breton area samples had large herring which were on average 5 cm longer.

The Chaleur Bay samples were composed of 71% fall spawners while the Cape Breton area had 96% fall spawners.

1991 Survey (Oct. 10 - 24)

The 1991 set locations can be found on Figures 4 and 5, per strata location in Table 6. Length frequency distributions of herring samples are shown in Figure 9a for Chaleur Bay and 9b for Cape Breton.

All sets in both areas were composed of adult herring, except for a small proportion of juveniles in the West Miscou set. Larger herring were again found in the Cape Breton area samples. Chaleur Bay samples consisted of 68% fall spawners while Cape Breton had 99%.

1990 Survey (Oct. 26 - Nov. 8)

Set locations for the 1990 survey can be found on Figures 6 and 7, plus per strata distribution in Table 7. Length frequency distributions of herring samples are shown in Figure 10.

In Chaleur Bay, over 80% of herring backscatter was found in the western end, with samples composed primarily of juvenile herring. Adult herring were found in the eastern Chaleur Bay samples. Some smelt were present in sets from New Richmond (80%), Richmond offshore (8%) and Carlisle offshore (5%). Larger adult herring were found in the Cape Breton area samples.

Due mainly to the large number of juvenile herring samples which were mostly spring spawners, the total Chaleur Bay area samples consisted of 32% fall spawners while Cape Breton samples were composed of 92% fall spawners.

Catch-at-age

Catch-at-age for 4T-4Vn herring combined weighed by the total backscatter proportions for each area (Chaleur and Cape Breton) is presented in Table 11.

The fall spawners represented 81.6% of the 1992 total backscatter, and 74.7% in 1991. In 1990, this percentage was down to 49.1%, mainly because of the large proportion of juveniles which are mostly spring spawners. The strong 1987 fall year-class accounts for 36% of fall spawners in 1991 and 29% in 1992.

For the spring spawners, the strongest year-class was in 1988 which accounted for 29% of the 1990 biomass. The large amounts of juveniles found in 1990 were mostly spring spawners; ages 1 and 2 accounting for 46% of the total backscatter.

Temperature and Salinity

The TS (temperature-salinity) plots by area derived from the CTD profiles encompass all the temperature and salinity data points over all depth ranges. Figure 11 summarizes the 1992 acoustic cruise data while the 1991 temperature-salinity plots by area are shown in Figure 12. Temperatures in all areas ranged between 0 and 12 °C for both years. In 1992, the Cape Breton area had a narrower range of temperatures (from 2 to 4 °C) and a wider salinity range than in 1991. The east Chaleur and Gaspe areas have quite similar patterns for both years. Salinity gradients were stronger in the inshore strata of the western part of the Chaleur Bay in 1991. In general, stronger haloclynes and thermoclines were observed in the inshore strata.

DISCUSSION

The 1992 acoustic survey held from Oct. 1 to Oct. 22 was the most extensive of Gulf Region acoustic surveys; furthermore, no major equipment failure or cable breaks occurred. This survey had the highest proportion of transects with backscatter recorded and was close to the 1991 value for highest mileage covered with backscatter recorded. This suggests a more widespread distribution of herring in both the Chaleur Bay area and northern Cape Breton. A ball calibration was done on our acoustic equipment on May 11th, 1993 in conjunction with the TVG calibration, to confirm the receiver fixed gain and digitizer gain. The calibration files were within 0.2 dB of the ball calibration results, and thus assumed to be correct. The biomass estimate derived from these TVG calibration files and our calculated target strengths for 1992 was 203797 tons. This value is lower than the VPA model using the ADAPT framework in the assessment for 4T fall spawners, 1992 (Chaput et al. 1993).

The 1991 acoustic survey held from Oct. 10 to Oct. 24 was marred with equipment failure and cable breaks. The splicing of the cable and motherboard change, plus the inability to quantify the variation in fixed gain resulting from that change, make our 1991 estimate questionable. Other indicators such as the highest mileage covered with reported backscatter and a high proportion of transects with backscatter would indicate that the 1991 distribution and abundance would be similar to 1992.

The 1990 survey held from Oct. 26 to Nov. 8 had a biomass estimate which was high compared to 1991 and 1992. No major equipment problem occurred, although there were some cable problems and splicing was done. The TVG set at 40 log R could affect quantification by increasing the estimate of low amplitude signals (Allen Clay, pers. comm.). The large proportion of the biomass estimate attributed to juvenile herring could reflect the large fall 87 and spring 88 year classes. However, this large biomass estimate does not coincide with other indicators. The 1990 survey had the lowest proportion of transects and the lowest mileage covered with reported backscatter, compared to 1991 and 1992. The equipment change in 1991 and poor logbook records of transceiver settings in 1990 could be possible sources of error.

The proportion of backscatter recorded during nighttime hours was fairly constant, between 75 and 80% for the years 1990 to 1992. Any daytime overestimate of biomass derived by applying nighttime target strengths to daytime backscatter would be relatively constant over this time period.

ACKNOWLEDGEMENTS

Sincere thanks go to Clarence Bourque and Collin McDougall who did the laboratory work and ageing of collected samples. Thanks are also due to Fran Mowbray for her work on the catch-at-age matrix, David Cairns, Hélène Dupuis and Mike Chadwick for their participation in the 1990 and 1991 surveys as well as their suggestions and advice. We cannot forget Udo Buerkle and Martin Castonguay for looking at some data and providing processing advice, and Allen Clay for his continuous help and tutoring on the HDPS software and calibration. Finally, thanks go out to all the scientific as well as Ship's Branch personnel who participated in the 1990, 1991 and 1992 acoustic surveys.

Appendix 1. Formulas used in calculating values given in Tables 2-8. Unless otherwise indicated, lengths are in m, areas are in m^2 , time is in hours, area scattering coefficient is in sr^{-1} , total backscattering is in $m^2 sr^{-1}$, and mass is in tonnes.

Table 2-4 Formulas for individual transects

$$\text{Transect area} = 200 \times \text{transect length}$$

$$\text{Target strength} = (20 \log \text{length} - 71.9) + 10 \log \text{weight}$$

in dB kg

Notes: This equation is from Foote (1987). Length is mean length of fish in cm. Weight is mean weight in kg at this length.

$$\text{Total backscattering} = \text{transect area} \times \text{area scattering coefficient}$$

$$\text{Biomass density} = \frac{\text{Area scattering coefficient}}{\left(\frac{\text{target strength}}{10} \right)}$$

$$\text{Total biomass in tonnes transect} = \frac{0.001 \times \text{total backscattering}}{\left(\frac{\text{target strength}}{10} \right)}$$

Table 5-7 Formulas for strata

$$\text{Weighting factor} = \frac{\text{transect area}}{\text{mean transect area}}$$

$$\text{Stratum area} = \frac{1}{\text{scattering coefficient}} \times \sum \text{weighting factor} \times \text{area scattering coefficient for each transect}$$

$$\text{Mean total backscattering per stratum} = \text{stratum area scattering coefficient} \times \text{stratum area}$$

$$\text{Variance of area scattering coefficient} = \frac{\sum \text{weighting}^2 \times \left(\text{area scattering} - \frac{\text{mean of weighted area scattering coefficient}}{\text{area scattering coefficient}} \right)^2}{\text{number of transects} \times (\text{number of transects} - 1)}$$

$$\text{Variance of total backscattering} = \frac{(\text{stratum})^2}{\text{area}} \times \text{variance of area scattering coefficient}$$

$$\text{Standard error of total backscattering} = \sqrt{\text{variance of total backscattering}}$$

$$\begin{aligned} \text{Stratum biomass density} &= \frac{\text{stratum area scattering coefficient}}{10} \\ &\quad \left(\frac{\text{target strength}}{10} \right) \\ &\text{in kg m}^{-2} \end{aligned}$$

$$\text{Total stratum biomass} = 0.001 \times \text{stratum area} \times \text{stratum biomass density}$$

$$\begin{aligned} \text{Variance of biomass density} &= \sum_{\text{number of transects} \times (\text{number of transects} - 1)} \frac{\text{weighting}^2 \times (\text{biomass density} - \text{mean of weighted biomass density})^2}{\text{factor}} \end{aligned}$$

$$\begin{aligned} \text{Standard error of total stratum biomass} &= \sqrt{0.001^2 \times \text{stratum area}^2 \times \text{variance of biomass density}} \end{aligned}$$

Table 8 Formulas for survey areas

$$\text{Mean total backscattering per survey area} = \sum \text{total backscattering for strata in survey area}$$

$$\text{Variance total backscattering per survey area} = \sum_{\text{survey area}} \text{stratum}^2 \times \text{variance of stratum area scattering coefficient}$$

$$\begin{aligned} \text{Coefficient of variation of total backscattering per survey area} &= \frac{\sqrt{\text{variance total backscattering per survey area}}}{\text{mean total backscattering per survey area}} \end{aligned}$$

$$\text{Mean biomass per survey area} = \sum \text{biomass for strata in survey area}$$

$$\text{Variance of biomass per survey area} = 0.001^2 \times \sum_{\text{area}} \text{stratum}^2 \times \text{variance biomass density within strata}$$

$$\begin{aligned} \text{Coefficient of variation of biomass per survey area} &= \frac{\sqrt{\text{variance of biomass per survey area}}}{\text{mean biomass per survey area}} \end{aligned}$$
