¹This series documents the scientific basic for the evaluation of fisheries resources in Atlantic Canada. As such, it addresses the issues of the day in the time frames required and the documents it contains are not intended as definitive statements on the subjects addressed but rather as progress reports on ongoing investigations.

Research documents are produced in the official language in which they are provided to the secretariat.

¹La présente série documente les bases scientifiques des évaluations des ressources halieutiques sur la côte Atlantique du Canada. Elle traite des problèmes courants selon les échéanciers dictés. Les documents qu'elle contient ne doivent pas être considérés comme des énoncés définitifs sur les sujets traités, mais plutôt comme des rapports d'étape sur les études en cours.

Les documents de recherche sont publiés dans la langue officielle utilisée dans le manuscrit envoyé au secrétariat.

ABSTRACT

The provisional landings of witch flounder in NAFO Divisions 4R and 4S totalled 453 t in 1991 and 376 t in 1992. A summertime seine fishery contributed most of the 374 t originating from 4R in 1991 (332 t in 1992). The landings of witch in 4RS during 1991 and 1992 are among the lowest within the available data series beginning in 1960. Research surveys of 4RS, conducted during summer and winter since 1983, indicate a reduction in abundance in 4R since 1983. Summer surveys of 4S indicate a similar decline since 1986. Abundance indices based on winter surveys in 4S vary from year to year, largely due to limited strata coverage. Although 4T is not included as part of any witch management unit, research surveys in 4T caught significant numbers of witch near the 4S border and significant commercial catches of witch have been reported from 4T since 1984. The current stock unit definition may not be appropriate.

RÉSUMÉ

Selon les données provisoires, les débarquements de la plie grise dans les divisions 4R et 4S de l'OPANO ont atteint 453 t en 1991 et 376 t en 1992. La pêche estivale par les seigneurs a contribué la majeure partie des 374 t provenant de 4R en 1991 et des 332 t en 1992. Les débarquements de plie grise dans les divisions 4RS en 1991 et 1992 sont près des plus bas niveaux parmi les données disponibles depuis 1960. Les relevés scientifiques, effectués dans 4RS durant l'été et l'hiver depuis 1983, indiquent une réduction dans l'abondance de plie grise de 4R depuis 1983. Les relevés estivaux de 4S indiquent une réduction semblable depuis 1986. Les indices d'abondance qui sont basés sur les relevés d'hiver varient d'une année à l'autre selon le degré de couverture des strates. La plie grise de 4T n'est pas reconnue comme faisant partie de l'unité de stock 4RS. Cependant, des captures importantes sont enregistrées dans les strates qui bordent la zone 4S lors des relevés scientifiques et une pêche relativement importante de plie grise est rapportée dans la Division 4T. Ceci laisse croire que la définition de l'unité de stock est à reconsidérer.

INTRODUCTION

Witch flounder (*Glyptocephalus cynoglossus*) occur in the western North Atlantic from southern Labrador in the north, as far south as the Gulf of Maine and North Carolina (Scott and Scott 1988). Witch flounder are frequently associated with mud and mud-sand bottoms, at depths of 180-366 m and temperatures ranging 2-6°C (Powles and Kohler 1970, Bowering 1976).

The witch flounder commercial fishery first developed along with the introduction of otter trawling to Newfoundland in the 1940s. The fishery began to exploit Gulf of St. Lawrence stocks in the 1950s when declining catches by Danish seiners in Fortune Bay, Newfoundland (NAFO Division 3Ps) caused the fleet to move to St. George's Bay (4R) (Bowering 1979). A small directed fishery for witch developed in St. Georges Bay during the summertime, while in the winter, witch became a bycatch of cod and redfish-directed fisheries. The witch flounder fishery expanded in the Gulf from St. George's Bay during the 1970s to the Esquiman Channel and the northern shores of Cape Breton Island.

Witch flounder fisheries came under international quota regulation in 1974; at the same time, stock unit areas were defined on the basis of current biological information. In 1977, a precautionary quota of 3,500 t was set for Division 4RS, based on catch statistics. The first analytical assessment of 4RS witch was conducted in 1978 (Bowering 1978). Research data on this stock were analysed yearly up to 1981 (Bowering and Brodie 1980, Bowering 1981), but have not included catch-at-age data since then. The Groundfish Subcommittee of CAFSAC continued to review the status of the stock yearly mostly on the basis of landed catches. In 1991, Tallman and Forest-Gallant combined information on catch statistics and research survey data in their assessment of the status of 4RS witch. In this document, we update the status of witch flounder in 4RS based on catch statistics and summary analysis of survey catch data from 1991 and 1992. The Groundfish Subcommittee of CAFSAC recommended in 1990 that witch and other flatfishes be assessed every three years, unless otherwise recommended by the fishing industry.

Description of the fishery

Landings of witch flounder in 4RS during 1991 and 1992 were near their lowest level since 1960 (Tables 1, 2, 3). Otter trawls contributed most of the annual witch landings until 1980 in 4R. Since 1981, seining gear has increasingly dominated witch landings in 4R (Table 1). Otter trawls continue to contribute the majority of witch landings in 4S where landings totalled 45 t in 1992, well below the long-term average of 312 t (Table 2). Between 1991 and 1992, there was a noticeable reduction in the number of gear types that contributed to witch landings in 4R and 4S (Tables 5 and 6). The winter fishery for witch that was concentrated in the months of January and February during the late 1970s (Lafleur and Lussiaà-Berdou 1982), was no longer present in 1991 and 1992 (Tables 4 and 5). In general, the 4RS witch fishery now concentrates during the mid summer and autumn months (Table 6).

The status of 4RS witch as a discrete stock has been a longstanding issue. Bowering (1978) questionned whether witch fished in 4T off northern Cape Breton should not be considered as part of the 4RS stock. Lafleur and Lussiaà-Berdou (1982) suggested that 4RS witch comprised two stocks based on differences in the size composition, growth rates and mortality between 4R and 4S. Tallman and Gallant (1991) noted significant numbers of witch flounder in research surveys of 4T strata that border 4RS. Figure 1 shows landings of 4R, 4S and 4T witch since 1963. The 4R witch fishery dominated landings through the latter part of the 1960s and most of the 1970s; however, since 1984 the 4T fishery contributes most of the Gulf landings of witch flounder. This may be further evidence that the current stock unit definition is inappropriate.

Bowering (1978) described the 4RS witch stock as composed of numerous old (up to age 26 years), slow-growing fish. Many of these were landed in "jellied" condition, providing a poor market product. In 1979, the TAC on the stock was raised from 3,500 t to 5,000 t in order to remove the slow-growing component of the stock and improve growth rates of younger witch. Between 1976 and 1981, the growth rates of male and female witch increased significantly, the life span decreased from 26 to 16 years, while stock biomass and size at maturity remained stable (reviewed by Bowering and Brodie 1984). Although the management plan succeeded in removing the large aged component of the population, landings of witch in 4RS peaked in 1976 and declined in following years (Table 3), failing to reach the TAC of 5,000 t. In 1982, the TAC was returned to 3,500 t and has not been changed since then.

Research survey data

Seasonal research vessel surveys of groundfish have been conducted in the northern Gulf since 1983 by the Quebec Region of DFO (Figure 2). Summer surveys were conducted from 1984 to 1989 with the *Lady Hammond*, fishing mainly for redfish. In 1990, the *Lady Hammond* was replaced by the *Alfred Needler*, with the purpose of combining concurrent surveys for redfish and shrimp. In addition to changing vessels, the *Alfred Needler* deployed a different trawl and reduced the speed and duration of tows. The Statistics, Sampling and Surveys Subcommittee of CAFSAC reviewed the data from a comparative survey conducted in 1990 and concluded that it was not possible to derive a conversion factor for the two vessels. Comparing data on witch catches from the two vessels, it was noted that the size composition was similar for the two vessels but that the *Alfred Needler* caught approximately half as much witch and American plaice as the *Lady Hammond*.

Mean numbers per tow by stratum and weighted division means are presented in Table 7 for winter surveys of the *Gadus Atlantica*. Several strata were missed in certain years due to ice and weather conditions, particularly in NAFO Division 4S. Similar data are presented in Table 8 for summer surveys. The longterm trend in mean numbers per tow from surveys indicates declining abundance in 4R since 1983. Summer surveys of 4S indicate a similar pattern of declining abundance since 1986 (Table 8), although part of this decline is attributed to the effect of changes in research vessels. The mean abundance of witch in winter surveys of 4S have fluctuated widely from year to year, largely due to variations in strata coverage. Winter surveys since 1991 indicate high concentrations of witch in the Laurentian Channel, including 4T strata (Table 7). Surveys conducted during recent summers indicate average catches in the upper Gulf (4T strata 411-414) that are well above the mean for 4RST (Table 8).

Minimum stock biomass was calculated in 4R, 4S and 4T based on research vessel surveys for years with sufficient coverage. The results from summer surveys (Table 9) indicate declining biomass in all divisions and increasing proportion of the biomass found in 4T. Abundance estimates from winter surveys in 4S varied widely over time and exhibit no clear trend; however, strata coverage was frequently limited during the winter surveys, contributing to the observed variability in catch.

Prognosis

Biological information on 4RS witch has not been brought up to date since the early 1980s; however, it appears from both commercial catches and survey data that the abundance of witch in 4RS is in decline. The current TAC of 3,500 t is high in relation to catches since 1981. The current stock unit definition may be inappropriate.

Acknowledgements

Survey data in this report were provided by the Québec Region of DFO. We particularly thank Alain Fréchet for providing summaries of survey data on witch flounder.
