AN ASSESSMENT OF THE COD STOCK IN NAFO DIVISIONS 2J3KL

by

J.W. Baird, C.A. Bishop, W.B. Brodie and E.F. Murphy
Science Branch
Department of Fisheries and Oceans
P.O. Box 5667
St. John's, Newfoundland A1C 5X1

¹This series documents the scientific basis for fisheries management advice in Atlantic Canada. As such, it addresses the issues of the day in the time frames required and the Research Documents it contains are not intended as definitive statements on the subjects addressed but rather as progress reports on ongoing investigations.

Research Documents are produced in the official language in which they are provided to the secretariat by the author.

¹Cette série documente les bases scientifiques des conseils de gestion des pêches sur la côte atlantique du Canada. Comme telle, elle couvre les problèmes actuels selon les échéanciers voulus et les Documents de recherche qu'elle contient ne doivent pas être considérés comme des énoncés finals sur les sujets traités mais plutôt comme des rapports d'étape sur les études en cours.

Les Documents de recherche sont publiés dans la langue officielle utilisée par les auteurs dans le manuscrit envoyé au secrétariat.

Abstract

Catches for this stock were highest during the 1960s with a peak catch of 800,000 t occurring in 1968. Catches declined during the 1970s with subsequent increases. During the late 1980s catches ranged between 230,000 and 270,000 t but have recently declined as TACs are reduced. Both ADAPT and Laurec-Shepherd analyses were used in an effort to determine terminal year stock size. There is little doubt that the stock is at a low level regardless of which calibration technique is used. The age 3+ biomass and even more disturbing, the age 7+ biomass (approximately the SSB) are currently at or near the lowest levels ever observed for this stock. The fishery in 1992 will be dominated by only two year classes, those of 1986 and 1987. The limited information available indicated that the 1988 yearclass is below average, and is currently estimated to be about the level of the weak 1983 and 1984 year classes.

Résumé

Les prises dans le stock considéré ont été à leur plus fort durant les années 60, atteignant le chiffre record de 800 000 t en 1968. Elles ont fléchi au cours des années 70, pour augmenter ensuite à nouveau. À la fin des années 80, elles se situaient entre 230 000 et 270 000 t, mais elles ont récemment diminué par suite de la réduction des TPA. On a effectué des analyses au moyen des méthodes ADAPT et Laurec-Shepherd dans le but de déterminer la grosseur définitive du stock de dernière année. Or, quelle que soit la technique de étalonnage employée, il ne fait aucun doute que le niveau du stock est bas. La biomasse d'âge 3 + et, ce qui est plus inquiétant encore, celle d'âge 7 + (correspondant approximativement à la biomasse du stock reproducteur) sont proches du plus bas niveau jamais observé dans ce stock, si elles ne l'ont pas déjà atteint. En 1992, la pêche ne sera dominée que par deux classes d'âge, soit celles de 1986 et 1987. D'après les renseignements limités dont on dispose, la classe d'âge de 1988 est inférieure à la moyenne et on estime qu'elle se situe actuellement à peu près au niveau des classes d'âge de 1983 et 1984, qui étaient faibles.

Description of the Fishery

Historical data and the 1991 fishery

Nominal catches for this stock increased during the late 1950's and early 1960's and peaked at just over 800,000t during 1968 (**Table 1, Figure 1**). Catches rapidly declined thereafter and were at a low of 139,000 t in 1978. During 1982 to 1990 catches were in the range of 219,000 to 270,000t, however, a reduction to approximately 171,000t occurred during 1991. This reduction resulted in substantial shortfalls of catch relative to allowance/ allocation in the fixed gear and mobile gear fisheries (**Table 2**). These shortfalls in 1991 were 58,000t and 10,000t respectively. The total Canadian catch increased from a low of about 36,000t in 1974 to 214,000t in 1983. Catches then declined to 190,000t in 1986 but increased to a high of 242,000t in 1988. Since 1988 catches have again declined and in 1991 the Canadian catch was approximately 120,000t. This is the lowest Canadian catch since Canada extended it's fisheries jurisdiction.

Total allowable catches (TAC's) were first introduced for this stock in 1973 (**Table 1**) and during the 1973-1976 period were ineffective in restricting catches. During 1977 Canada extended fisheries jurisdiction to 200 nautical miles and TAC's were reduced to more restrictive levels.

During the 1960's, when the fishery was dominated by non-Canadian fleets (**Figure 3**), most of the catch occurred in Divisions 2J and 3L with 2J generally predominating (**Figure 2**). Since that time catches have been mainly from Divisions 2J and 3K. Canadian landings by TC-5 otter trawlers have shown considerable fluctuation between these divisions during the 1977-1986 period. In 1987 a management plan was put in place to distribute otter trawl catches equally among all 3 divisions. As a result catches were more evenly distributed during 1987-1989. In 1990 and 1991 severe ice conditions prohibited the otter trawl fleet from fishing in Division 2J during the winter months and during other months catch rates were low. This resulted in a shortfall in the offshore allocation in this division. The Canadian catch distribution for large otter trawlers by division during 1990 was 23% in Division 2J, 34% in Division 3K, and 43% in Division 3L, while for 1991 the distribution was 1%, 49% and 50% respectively.

Information from Canadian surveillance indicate that the catch by foreign fleets, mainly the EEC (Spain, Portugal and Germany), outside the 200 mile limit in Div. 3L was in the vicinity of 48,900t in 1991. This was substantially higher than catches reported for recent years but was similar to the high catch reported in 1986 (51,555t). The reported EEC catch (Portugal - 9459t; Spain - 8546t; and Germany - 6459t) for 1991 is about 40% lower than that estimated by surveillance. Approximately 20% of the 48,900t was estimated to have been taken by non-reporting, non-member countries of NAFO.

The catch by fixed gears (traps, gillnets, handlines and longlines) increased from a low of 35,000t in 1974 to 113,000t in 1982 (Table 1; Figure 1). Catches subsequently decreased to about 75,000t between 1985 and 1987 but increased to about 100,000t in 1988-89. The catch of 112,500t in 1990 was the highest since 1982 while that for 1991 of 60,000t was the lowest since 1976. The predominant gears in the fixed gear fishery are traps and gillnets. The decline in catch from 1990 to 1991 was observed for all gears (Table 3; Figure 4) but was most pronounced for gillnets with a decrease of over 70% from the 1990 level. Trap catches declined slightly from 1990 to 1991 but were comparable to those obtained in the 1986-89 period. In recent years a gillnet fishery has developed in the offshore area of Division 3L primarily in the area of the Virgin Rocks. In 1990 this fishery contributed about 20,000t of the total 27,000t gillnet catch for Div. 3L but in 1991 the catch by this gear component declined to about 7,900t from a total 3L gillnet catch of 10,900t. During 1991 an estimated 4,000t (Canadian Dept. of Fisheries and Oceans) of offshore gillnet catch, actually taken in Div. 3NO, was reported for Division 3L and was not included in the Division 3L catch. Some of the decline in gillnet catch could have been caused by the presence of poor to average year classes in the population at ages 6-8, ages which generally have been most abundant in Div. 2J3KL gillnet catches.

Catches by month for all gears for 1991 are presented in Table 4. Otter trawl landings were mainly in the autumn in Div. 2J, in the winter in Div. 3K and more widespread in Div. 3L with some preponderance toward the late autumn and winter periods. As in the past, fixed gear catches were mainly during the summer period. During 1991 the inshore fishery, relative to other years, was late starting, by about two to four weeks, in virtually all areas in the management unit (Davis, 1992). Drifting ice was a threat to fixed gear well into the month of July and grounded icebergs blocked some trap berths until about the same time. The codtrap fishery continued for some two to six weeks longer than usual.

A summary of catch and allocation/allowance data from recent years as obtained from the Canadian Management Plan is presented in Table 2. Canadian catches have been less than allocations for each year with major discrepancies occurring mainly between the fixed gear and its allowance. In 1991 the fixed gear catch was lower than the allowance by 49%, the largest discrepancy since an allowance was first introduced in 1978.

The fishery in 1992

The Canadian offshore fishery for cod in 1992 was virtually completed by March. Reduced catch rates, the presence of small fish and reduced allocations lead to reduction in fishing activity throughout the area. Cod were found mainly in southern 3K and northern 3L and predominantly in deeper waters. The total catch of cod to date in 1992 from Divisions 2J3KL was approximately 14,400t compared to 41,700t for the same months of 1991, a decline of about 65%. Virtually all the Canadian catch during these months, for both years, was taken by large (> 100') otter trawlers fishing in Divisions 3KL.

The foreign fleet fishing in the area outside the 200 mile zone on the Nose of the Grand Bank had also experienced lower catch rates along with catches of small fish during the early months of 1992. Low catch rates caused vessels from Germany to leave the zone early. The catch of cod by EC vessels in Division 3L for January to April of 1992, as estimated by Canadian surveillance, was approximately 6,900t, down from 21,600t estimated for the same months of 1991. This represents a decline of almost 70%. It can be seen from the following table that the total number of EC vessels observed in the NAFO Regulatory Area did not change much between 1991 and 1992, therefore the large decline in catch is more likely due to lower abundance in the area outside 200 miles than a reduction in fishing effort.

EC fishing vessels observed in the NAFO Regulatory Area				
Year	January	February	March	April
1991	51	55	80	85
1992	60	74	77	75

Environmental conditions in 1991

The following is a summary of some of the information presented at CAFSAC's Fisheries Oceanography Subcommittee meeting held in April, 1992. Environmental observations for the waters off northern and eastern Newfoundland indicated that water temperatures were below normal in 1991. The areal extent of ice coverage was greater than normal and persisted for a longer period of time. Ice was present in inshore waters well into the summer and records were set for last presence of ice. Low ocean temperatures persisted throughout the summer and early autumn and negative anomalies extended from the Labrador Shelf to southern Nfld. with the largest occurring on the Grand Banks. Temperatures in the bottom water layers (75-175 m) continued a declining trend that commenced in the mid-1980's. The areal extent of the cold intermediate layer (CIL) of the Labrador Current (waters < 0° C) was at or near its long term maximum. Bottom temperatures for 1992 are expected to be slightly higher than in 1991 but will remain below normal. The extent of the CIL is expected to remain large in 1992 as well.

The influence of these conditions on the cod stock and the fisheries in Divisions 2J3KL has not been determined. Evidence from hydroacoustic surveys conducted during February and the commercial offshore fishery suggests that cod have been moving to deeper water on the slopes of offshore banks during winter months. Surveys conducted during autumn also indicate higher proportions of biomass in deep water strata, however, it is not clear whether this can be attributed to actual distributional changes or a reduction in biomass in the shallow water strata. Examination of research vessel length frequency data did not support the hypothesis of larger fish residing in the deeper water. The low inshore catches in the northern areas were coincidental with colder than normal water masses although other

factors (eg. stock abundance) might have played a role either by themselves or in concert with the environment. The declining trend in survey biomass is most pronounced in the north. Data from surveys in Div. 2GH would also support this trend which may be the result of long term and large scale environmental changes.

Catch and weight at age

A summary of the sampling used to derive the catch at age in 1991 is given in Table 5. Sampling was spread spatially and temporally over all gears with a total of about 4000 fish aged and 170,000 fish measured. The following relationship was applied in deriving average weight at age: $\log \text{weight} = 3.0879 \log \text{length} - 5.2106$. Sampling of the commercial catch in 1991 also included information on the Canadian offshore gillnet fishery in Division 3L. Coefficients of variation on the estimated catch at age were less than 10% for most ages (Table 6). The 1985 to 1987 yearclasses were the most abundant in the commercial catch in 1991. The 1986 and 1987 yearclasses dominated the fixed gear fishery in 1991 while ages 5 and 6 (1985 and 86 yearclasses) were dominant in the offshore mobile gear fishery (Table 7, Figure 5).

The age composition of the catch by foreign fleets fishing outside the 200 mile zone in 1991 was estimated by applying age/length keys from the Canadian 3L offshore fishery or spring RV surveys to length frequencies provided by EEC countries (Spain, Portugal and Germany). For the January 1992 CAFSAC assessment, sampling data for the foreign catch outside 200 miles was not available for all countries. The 1992 revised total catch at age indicated fewer cod at ages 3-5 than was the case in January (Figure 6). Ages 5 and 6 dominated the Canadian and French otter trawl fisheries while ages 4 and 5 were dominant in the EEC catch (Table 7). The observed and predicted proportions at age for the 1991 catch are presented in Figure 7. Relatively fewer fish were caught at older ages than was expected.

Age compositions of the 1990 cod catch by Spain and Portugal outside 200 miles were made available at the 1991 June NAFO meeting and were included in a revision of the 1990 catch at age. A comparison of the original and revised age compositions indicates that more fish at younger ages were taken in 1991 than had previously been estimated (Figure 6).

At the 1991 assessment of this stock CAFSAC recommended that age compositions from Canadian spring RV surveys be evaluated for their potential use in adjusting foreign catches outside 200 miles. It was previously determined that autumn surveys were not appropriate for this purpose. Results showed, for years with enough information to make comparisons, that spring RV surveys included proportionately more fish at younger ages than was indicated by either Canadian or foreign sampling (Figure 8).

The catch numbers, biomass and average weights at age for years 1962 to 1991 are presented in Tables 8 to 10. The total catch at age for 1991 indicates that the 1986

yearclass was most abundant with the highest catch at that age since 1974. The relatively high catch at age 4 and low catches at age 7 and 8 are consistent with population age structure from the 1991 assessment of this stock (Baird et al., 1991) showing strong 1987 and weak 1983 and 84 yearclasses. Weights at age for the 1962-71 period are estimates obtained using weight-at-age data for 1964-68 from Division 2J and 1965-70 from Divisions 3KL weighted by divisional catch. Average weights increased from the early 1970s to the early 1980s and subsequently declined. The 1991 average weights at age compared with those from recent years are lower at ages 4 and 5 but slightly higher for ages 7 and older. In general no trend in commercial fishery mean weights at age has been observed during the past several years (Figure 9). The catch biomass at age for 1991 obtained using sampling data was approximately 98% of that reported.

Research vessel survey data

Stratified-random trawl surveys

Research vessel surveys have been conducted by Canada during autumn in Division 2J, 3K, and 3L since 1977, 1978, and 1981 respectively. The 1984 autumn survey in Division 3L was conducted earlier in the year than the other surveys (August-September as opposed to October-November). Spring surveys have been conducted by Canada in Division 3L for the years 1971-82 and 1985-91. Surveys in Divisions 2J3K have been conducted by R.V. GADUS ATLANTICA while those in Division 3L have been conducted by R.V. A.T.CAMERON (1971-82) and R.V. WILFRED TEMPLEMAN (1983-91). To account for incomplete coverage of strata in certain years, estimates of biomass and abundance for non-sampled strata were obtained using a multiplicative model. Stratification charts used for the surveys in the three NAFO Divisions are presented in Figures 10-12.

Divisional survey estimates of biomass and abundance have shown large fluctuations in recent years. The low values observed in 1991 in Division 2J were similar to those from the 1990 survey (Tables 11-12, Figure 13). Biomass estimates have indicated a declining trend since 1988, a similar trend for abundance to 1990 with a slight increase in 1991. Both biomass and abundance declined substantially in Divisions 3K and 3L from 1990 to 1991 (Tables 13-16, Figures 14-15). The 1991 estimates for Division 3L were the lowest in the time series. The total RV biomass for Division 2J3KL cod in 1991 was about half that estimated for 1990 (Figure 17) and the lowest since 1981, the first year that all three divisions were surveyed during the same season. In all the autumn surveys cod abundance and biomass were low in the shallow water strata. This was particularly true for Division 3L where in contrast to previous years, cod were found in low numbers in large strata in the 31-50 fathom depth range. The 1991 estimates for the Division 3L spring surveys also declined substantially and were the lowest in the time series since 1977 (Tables 17-18, Figure 16). However, several strata, which had high abundance estimates in previous years, particularly in 1990, could not be fished because of ice coverage.

Percent biomass by division (Table 19) was fairly stable for a period in the early 1980s and averaged about one third in each of the three divisions. In recent years the percentages have become quite variable with the highest and lowest percents for each of the three divisions occurring since 1987. The average percentages for the 1981-91 period are 36% in Division 2J, 36% in Division 3K, and 28% in Division 3L.

As recommended by the SSS Subcommittee of CAFSAC, the adaptive survey design used to minimize variance was discontinued in 1991. To meet similar objectives an alternate method of set to strata allocation was used which selected sets based on previous years data (Gagnon, 1991). For the autumn 1991 surveys, data for the 1986-90 period were used in the selection procedure.

Tables 20-23 give the mean numbers per tow at age for the surveys conducted in all divisions. The values include adjustments to account for strata omitted during some surveys. In Divisions 2J and 3K the 1987 yearclass (age 4) dominated in 1991. In Division 3L during spring and autumn the 1986 and 1987 yearclass (ages 4 and 5) were dominant in 1991 at similar levels of abundance.

There were no autumn surveys in Division 3L for the years 1978-80, so an index for these years was estimated by averaging yearclass estimates in successive spring surveys in Division 3L for 1977-81. The total stock area index at age for autumn was then calculated by averaging (weighted by surveyed area) the results for all three divisions. The surveyed area, in square nautical miles, used as weights for this average are: 2J - 21,560; 3K - 29,256; 3L - 36,777. This 2J3KL index (Table 24) indicated that although the total abundance had declined substantially the 1987 yearclass, age 4 in 1990, was still above average while the 1986 yearclass was similar in abundance with the average. Coefficients of variation for the age-by age means are also presented in Table 24. Numbers per tow at ages 1-5 are on par with those estimated from previous surveys and are slightly above the average for these ages in the RV time series. On the other hand, the numbers of cod at ages 6+ are the lowest in the series (Figure 18). The observed survey numbers per tow at age in 1991 are much lower at every age than those predicted from last years ADAPT. This is not surprising given the large decline in total RV biomass. What is surprising, however, is that the decline is much greater at older ages (Figure 19).

The reasons for this decline are not known. The 1991 survey was conducted using gear and methodologies similar to those of previous years to ensure no systematic change in catchability, though variation may occur. A fall survey in 1991 in Div. 2GH did not suggest migrations of cod to this area, as the biomass in 2GH was very low (Murphy et. al., 1992). A comparison of age structure and biomass distribution of cod from 1991 spring and fall RV surveys in Div. 3L and 3NO indicated that there may have been some movement from 3L to 3NO in 1991 but the increase in 3NO biomass in 1991 with its associated age composition is insufficient to explain the decline in Division 3L (Bishop et. al, 1992). The 3NO fall survey has only been conducted during 1990 and 1991 and the differences observed could be the result of annual survey variation.

There was no information to suggest that vertical migration away from the area swept by the trawl was a factor. At the beginning of the 1991 autumn survey a hydroacoustic experiment was conducted in a small area in Div. 2J and 3K. The results indicated that densities were low in the area and very few cod were observed in the water column above the standard bottom trawl. In addition, sounder watches maintained throughout the survey did not indicate concentrations of cod in the water column above the trawl.

As reported previously, the inshore fishery was later in 1991 and in some areas good catches persisted until late in the fall. This might suggest that a higher proportion of the stock remained in inshore areas at the time of the autumn surveys. However, it was noted that abundance in survey strata close to inshore areas was low.

With the fishery by foreign countries on the Nose of the Grand Bank estimated to be almost 50,000t in 1991, the status of the biomass in this area is of increased interest. The proportion of cod biomass, as determined by RV surveys, that occurs outside 200 miles in Division 3L is usually less than 10% and often less than 5% of the divisional biomass during spring and autumn. However, two winter surveys in this division, conducted during 1985 and 1986, indicate that about 25% of the 3L biomass occurs outside 200 miles during that season (Figure 20). It is during winter that the foreign fishery is at its height.

Survey average weights at age are presented in Tables 25-28. In Division 2J and 3K average weights have declined since 1989 at ages 4 to 6 while remaining stable or showing some increase at older ages. Recent average weights are substantially lower than those observed in the early to mid 1980's. In Div. 3L a similar pattern of reduced average weights at ages 4-6 were seen from 1990 to 1991. Estimates were also lower than those from the early to mid 1980's.

Winter hydroacoustic surveys

An annual winter hydroacoustic survey series for cod in Divs. 2J3KL was started in 1987. Several years were involved in developing the appropriate acoustic hardware and vessel technology that would permit the acquisition of data necessary to estimate the abundance of cod from electronic records. The purpose of these surveys is to determine the abundance and distribution of cod on the seaward slopes of the offshore banks within the management unit (Figure 21). Only in 1991 and 1992 were sufficient data collected to produce such estimates. Similar information for years prior to 1991 could not be obtained because of problems encountered with hydroacoustic hardware and operation of vessel and gear particularly with respect to ice conditions. During all years, however, information was obtained on the general distribution of cod in the area surveyed (Baird et al, 1992).

In the initial survey (1987) a large concentration was observed in southern 2J and northern 3K at depths ranging from 300 to 500 meters. In 1988 and 1989 the major concentration was found slightly further south but in the same depth zone. In the 1990 survey commercial concentrations of cod were found still further south in Division 3K and mainly at 550m,

about 150m deeper than in previous years. The general distribution and size range of cod encountered throughout the survey area during 1991 and 1992 were similar to those determined from the trawl surveys conducted during the previous respective autumns. Mean densities in 2J were lower, about the same in 3K, and about 75% lower in 3L in 1992 compared to 1991. In general the 1992 acoustic data obtained from surveys conducted during February indicated that cod densities were lower in 1992 than in 1991 and that fish were smaller and more dispersed. The results for Div. 3K and 3L indicated levels of reduction from 1991 to 1992 similar to those observed from the autumn trawl surveys during these years. In 1991 a large concentration of commercial sized cod was found in the southern most area of 3K between the depths of 600 and 850 m. This concentration was most dense at 700-800 m and extended into the northern part of 3L. In 1992 cod were generally dispersed throughout 3K and 3L in depths from 350 to 550m, with some fairly dense aggregations observed in northern 3L. Length frequencies indicated that most of the cod were between 37 and 43 cm in length.

Migration Research - Summer Hydroacoustics

Research on the movement and distribution of 2J3KL cod during the post spawning onshore migration in the spring of 1990 and 1991 has indicated that during both years, cod migrated onshore in large size-structured aggregations through a "pathway" defined by the bathymetry and temperature (2°C) (George Rose, pers. comm.). The timing of the passage through the "pathway" was approximately two weeks later in 1991 than in 1990. However the 1990 inshore catch was itself two weeks later than average. The size distributions differed markedly between years. Large fish (>60 cm) observed in quantity in 1990 could not be found in 1991 despite widespread search patterns in northern 3L and 3K using 2 vessels equipped with dual-beam echosounders and bottom trawls. Average densities within the aggregations recorded in 1991 were well below those recorded for 1990 based on acoustic integration and counting methods and trawl catches.

Cod and seal scouting survey, 1992

A cod and seal scouting survey was conducted in 2J3KL by two Canadian commercial trawlers charted to the Dept. of Fisheries and Oceans during April 1992. Using a line survey design these vessels covered an area similar to that surveyed during the February hydroacoustic survey (Figure 21). The results indicated the distribution and size range of cod observed was consistent with that observed in the hydroacoustic survey as well as with other surveys (cod tagging in January, 1992 and fall 1991 groundfish) and the commercial fishery. Observations on cod maturities gave comparable results with other recent studies and primarily indicated that cod were maturing at smaller lengths than had been observed in previous years.

Commercial catch rates

Multiplicative analysis of C/E

Offshore catch and effort data are analyzed using a multiplicative model (Gavaris, 1980) to account for country/gear, seasonal, and divisional differences for the years 1983-91. In previous assessments data for the years 1978-82 were also included in the C/E analysis. More recently the C/E for the 1978-82 period are not considered comparable to those of 1983-91 because of learning by the Canadian fleet during the late 1970's and the introduction of enterprise allocation and dockside grading during the early 1980's. It was recommended by CAFSAC that data for 1978-82 be excluded from future C/E standardization analyses. Information included in the current analysis was obtained from DFO and included Canadian (TC 4, 5, and 6) otter trawl catch rates. Plots of residuals indicated that data with greater catch and effort were less variable, therefore, estimated weights calculated according to Judge et al. (1980, p. 132) were applied in a weighted regression of the multiplicative model. To reduce the possible effects of truncation and rounding, data with less than 10 tons catch or 10 hours effort were excluded from the analysis.

The regression of ln catch rates explained about 68% of the variation in the data (Table 29). For the fleets included in this analysis Canadian (M) TC 6 otter trawlers were the most effective (Table 30), and the best catch rates overall occurred during the first quarter of the year. C/E increased from 1978 to 1985, declined to 1987-88 and increased again until 1990 (Table 31, Figure 22). The 1991 catch rate value is the lowest in the nine year time series.

A C/E index at age (Table 33) for 1983-91 was derived using the catch at age from the offshore fleet (Table 32) along with the calculated fishing effort from the C/E standardization (Table 31). This index indicates that the 1986 yearclass is relatively strong while the 1985 year class appears to be about average. The 1983 and 1984 yearclasses are weak. While this index indicates that the numbers of age 3-5 cod are a level similar to previous years the numbers of cod at ages 6 and older have declined and are at there lowest level since 1983 (Figure 23). The C/E at age observed during 1991 are lower than those predicted from the 1991 ADAPT (Figure 24). The reduction was relatively larger for older age groups, but the pattern is not as pronounced as that observed for the RV numbers at age.

Information derived from spatial techniques

Two additional pieces of commercial fishery information were evaluated for their potential use as abundance indicators. It was recommended by CAFSAC during the January, 1992 review of this stock, that an abundance index derived from application of the potential mapping techniques to observer data be made available for the current assessment. This

was done using SPANS to derive an aggregate index of biomass from catch rates and area fished in the offshore fishery (Kulka et al., 1992). The information used was obtained by observers at sea. An abundance index at age (Table 34) was then developed by applying the Canadian otter trawl age compositions (Table 32) to the SPANS aggregate biomass values. This index indicates that the numbers of age 6+ cod increased from 1985 to 1988 and then declined rapidly to a 9-year time series low in 1991 (Figure 25). The numbers of cod at ages 3-5 in 1991 are in the range of those observed during 1983-90. The authors of this index consider that more analysis is required to refine this technique and suggest that the current index be only used in a preliminary fashion. Some of the additional analysis will include an evaluation of the impact: the size of the primary sampling unit ("scanning circle"); and varying amounts of observer coverage for some years.

An index from the codtrap fishery

The second piece of commercial fishery data evaluated for its potential as an abundance index was the catch at age of cod traps for the 1978-91 period (Table 35). A recent analysis (Rose, 1992) indicated that aggregate codtrap catch lagged and weighted appropriately could be used as a predictor of stock size. The basic assumption of the original analysis was that effective codtrap fishing effort remained virtually constant over time because all "good" trap berths have been previously identified and are fished consistently. The codtrap at age index shows the same high value at ages 6+ for 1988 as did the SPANS index (Figure 26), however the 1991 index, for the same ages, is on par with or larger than values from 1978 to 1987. This is in contradiction to other indices of abundance examined (RV, C/E, SPANS). The trap index also indicates that the numbers of cod at ages 3-5 in 1990 and 1991 are among the highest in this 14 year time period. Because of the inconsistencies noted above this index should also be considered preliminary until an evaluation of the internal consistency of yearclass strength is completed.

Estimation of stock parameters

Description of formulations used with ADAPT

Several formulations of the adaptive framework (Gavaris, 1988) were examined in an effort to evaluate the new abundance indices and for the determination of stock size. A description of the various indices used is as follows:

- (1) RV ages 3-12 1978-91; C/E ages 5-12 1983-91
- (2) RV ages 3-12 1978-91
- (3) SPANS ages 3-12 1983-91
- (4) TRAP ages 3-10 1978-91
- (5) Combination of (2) and (3)
- (6) Combination of (2), (3) and (4)

The following structure was imposed:

- Natural mortality assumed 0.2
- Error in catch at age assumed negligible
- F on Age 13 set to 50% F on ages 7-9 (unweighted)
- F on age 13 for TRAP set to flat-top ages 7-9
- Intercepts not fitted
- Autumn RV related to November population
- C/E and SPANS related to January population
- TRAP related to July population

Formulation 1 RV & C/E (Table 36)

CV's on the estimated age 4-12 abundance are in the range of 18% to 30% while that on age 3 is 43%. CV's on all catchabilities are less than 15%. Bias is almost 10% on the age 3 abundance and between 2% and 5% for older ages. Bias on catchabilities for both indices are less than 1%. As had been noted at previous assessments of this stock, residuals indicate several year effects in the RV index and the C/E data displays a lack of fit.

Formulation 2 RV (Table 37)

CV's and biases are all a little larger than the RV and C/E combined formulation. Patterns of residuals are similar to those for the RV in Formulation 1, while population abundance was marginally lower and fishing mortality slightly higher.

Formulation 3 SPANS (Table 38)

Coefficients of variation are higher than was indicated by the two previous formulations with those on estimated abundances in the range of 30% to 55% and on catchabilities in the range of 18% to 20%. The higher CV's may be due in part to the shortness of the SPANS time series. The residual pattern is similar to the RV residuals in the above formulations for comparable years. This index gives higher population estimates than any of the other formulations.

Formulation 4 TRAP (Table 39)

CV's are similar to those in the SPANS calibration. Bias on the age 3 population is about 17%, but on age 4 and older fish are all less than 10%. An interesting point is there appears to be a negative year effect in 1986, the same year which is associated with a positive year effect in the RV. There seems to be some inconsistency in the strengths of estimated year classes compared to other formulations. The 1986 year class in this analysis, for example, is estimated to be larger than the 1986 year class. This is different for all other analyses.

Formulation 5 RV & SPANS (Table 40)

CV's and biases are at levels similar to the RV and C/E combined formulation. Residual patterns are consistent with patterns when each index is evaluated separately. Population numbers and fishing mortalities are similar to those from the RV only analysis.

Formulation 6 RV, SPANS & TRAP (Table 41)

CV's and biases are of the same order of magnitude as previous formulations. Residual patterns are also similar. Population and fishing mortality estimated are approximately centered in the range of estimated parameters from all other calibrations.

Laurec-Shepherd

Two formulations of the Laurec-Shepherd calibration technique were also evaluated for comparison with ADAPT results. RV and C/E were included in a single L/S run and the RV data was also included in an analysis. The results of the 2 index Laurec-Shepherd are presented in Table 42 with the RV only results given in Table 43. The structure for both analysis was the same as used for the ADAPT analysis. There was one exception, the F on the oldest age was set to 50% the average of the 5 previous ages (8-12). The results of these analyses suggest the population abundance is lower than the corresponding ADAPT runs. This can be explained by the weight each model places on the terminal year in the abundance indices.

Summary of Calibrations

When the C/E index was included with the RV data in a single ADAPT analysis, the residuals from the C/E relationships for the last three years of the series were virtually all positive, with 4 of the remaining 6 years having almost all negative residuals. Similar patterns in the C/E residuals, indicating lack of fit of this index to SPA, have been noted by the Subcommittee in the past. Because of the problems in interpreting this C/E series, it is recommended that this index be excluded from calibration. As the SPANS and codtrap indices at age are considered preliminary it was felt that their inclusion in a final calibration analysis would be premature.

Given the comments on the commercial C/E, SPANS index, and codtrap fishery data above, it was decided to use only the results of ADAPT and Laurec-Shepherd with RV data only for further analysis. If it can be determined that the large decline in RV biomass from 1990 to 1991 was caused by a change in availability then the results from ADAPT may be considered more appropriate. On the other hand if the drop in biomass was due to mortality then the Laurec-Shepherd results may be more indicative of stock status.

Regardless of the shortcomings of some of the calibration analyses, several of the features are similar (Table 44). Although the F's on ages 7-9 range from 0.30 to 1.42 in the various

calibrations the total age 3+ population abundance only ranges from 780 to 1300 million fish. If the optimistic SPANS results are excluded the range of the remaining three analyses is much smaller (780 to 1080 million fish). An examination of estimated yearclass size indicated that estimates of the 1988 Y/C, age 3 in 1991, are all less than 200 million fish. In addition all calibrations indicate the 1987 yearclass to be strong, the 1986 yearclass to be above average, and the 1983 and 1984 yearclasses weak.

Impact of data and assumptions on calibrations

To determine the effect of the amount of catch in the terminal year on the results of calibration another formulation with RV only was attempted using 25,000t as the size of the catch by non-Canadian fleets outside 200 miles during 1991. The results of this analysis are presented in Table 45. The precision estimates and residual patterns are very similar to the results from the original analysis. The age 3+ population abundance is 927 million fish and the age 7-9 mean F is about 0.6. The population only differs by less than 2% from the original analysis while the F is less by about 12%.

It appears that the models which have been explored adequately represent an increase in effective natural mortality (including emigration). As a consequence, the resulting pattern of population abundance and fishing mortality for the recent years is distorted and its interpretation requires care. The model formulation used with ADAPT would be more sensitive to major shifts in natural mortality.

Assessment Results

Fishing mortality and stock abundance (Figures 27, 28)

The ADAPT assessment indicated that the 1991 age 7-9 unweighted mean F is about 0.7 with the age 3+ population numbering about 940 million cod. The age 3+ population biomass is about 640 thousand tons and the SSB (7+) is 110 thousand tons. The analysis conducted using the Laurec-Shepherd technique gave a somewhat more pessimistic view of total abundance (780 million fish), 3+ biomass (520,000t in 1991), and SSB (72,000t) than the ADAPT analysis. The age 7-9 fishing mortality is also considerably higher at about 1.4. Both analyses indicated a sharp increase in fishing mortality from levels in the mid 1980's of around 0.5 to values between 0.7 and 1.0 (ADAPT) or greater than 1.0 (L/S) in 1989-91. The ADAPT calibration shows a decline in F in 1991, while the L/S indicated a continued increase in F to 1991. Both calibrations gave a radically different view of the recent trends in F compared to that observed in recent assessments of this stock.

The reason for the differences in the results from both calibration techniques is the treatment of the terminal year values of the abundance indices rather than a methodological difference. The model formulation used with ADAPT considers all RV estimates of a cohort to determine yearclass strength. The Laurec-Shepherd method estimates the current population at the same level as the current catchability-adjusted RV. The difference in

results therefore, can be attributed to differences in the degree of influence placed on each survey year. In this particular case, some of the disparity occurred because of different assumptions regarding the timing of the survey. The ADAPT formulation assumed that the survey index corresponded to the population fished until November (autumn RV) while the Laurec-Shepherd assumed that the survey corresponded to mid-year.

Although the use of the SPANS and codtrap indices in the calibration analyses should be treated with caution, both were included in exploratory analysis using ADAPT. The results of these preliminary calibration analyses were quite similar to ADAPT with only the RV data included (Table 44).

Recruitment (Figure 29)

The ADAPT calibration indicated the 1986 and 1987 yearclasses to be above average at 385 and 520 million cod respectively while the 1988 yearclass, age 3 in 1991, is well below average at approximately 175 million fish. The 1978-91 geometric mean recruitment for this stock since 1978 is now estimated to be about 270 million fish. The corresponding results from the L/S analysis were 300 and 450 million for the 1986 and 1987 year classes respectively. The 1988 year class was also estimated to be below average at about 165 million. The geometric mean recruitment since 1978 for the L/S analysis is 250 million fish.

Retrospective analysis

Retrospective analyses were conducted using both calibration techniques. Trends in mean F (Figure 30), population biomass (Figure 31), and catch, projected at an arbitrary F of 0.40 (Figure 32) were examined for retrospective patterns. Such patterns were present in some but not all years and it is quite clear that the terminal year population estimates, fishing mortalities and subsequent projected catches are very sensitive to changes in the abundance index used in calibration. In general, the ADAPT results are a little more optimistic than the L/S results. However, the ADAPT estimates were not adjusted for bias for this comparison. The L/S calibration gives more variable results when the index in the terminal year shows major changes from previous years, as seen in the 1986 and 1991 RV estimates.

The retrospective analysis from both methods indicates a sharp discontinuity between the 1990 and 1991 assessments. The analysis confirms that both models have not adequately captured the dynamics which occurred during 1990 and 1991. Estimates of mean F were similar with both methods, around 0.5, until 1989. The L/S shows a continual increase in F to 1991 while the F for the ADAPT analysis shows an increase in F followed by a decline. This difference is consistent with the different weighting of surveys in the terminal year by the two approaches.

Prognosis

In the face of uncertainty regarding which model formulation is most reliable, given the implications of either on the adult biomass, and the ancillary information suggesting a lack of fish in early 1992, catch projections to 1993 were not presented at this time. Before advice for 1993 can be provided data from the 1992 commercial fisheries and autumn research vessel survey should be reviewed. Therefore, only projections for various catch options for 1992 are provided.

With the uncertainty associated with the treatment of the terminal year in the calibration index, it was thought appropriate to conduct the standard suite of projections of catch, biomass and F using the results of both ADAPT and Laurec-Shepherd calibrations. Input parameters for projections are presented in Table 46. The weights at age were averages of values from the commercial fishery from 1989-1991. Partial recruitment values were determined for each analysis and were averages from fishing mortalities assuming full recruitment at ages 7-9 for the same period. Natural mortality was assumed to be 0.2. The 1989 and 1990 year classes at age 3 were set at 270 million for the ADAPT and 250 million for the L/S, each being the geometric mean recruitment from 1978-1991 from the respective analyses.

Projections were made at a range of fully recruited F's or catch options for 1992. Options included are $F_{0.1}$, twice $F_{0.1}$ (an approximation of F_{max}), 145,000t (the TAC with estimated foreign catch of 25,000t), and 100,000t (60,000t inshore catch, 15,000t offshore, and 25,000t foreign). The results of projections are shown in Table 47 and Figure 33. Regardless of which starting values are used the $F_{0.1}$ catch in 1992 is less than 100,000t and catches in the range of those taken in 1991 would generate fishing mortalities at or approaching 1.0.

There is little doubt that the stock is at a low level regardless of which calibration technique is used. The age 3+ biomass and even more disturbing, the age 7+ biomass (approximately the SSB) are currently at or near the lowest levels ever observed for this stock. The fishery in 1992 will be dominated by only two year classes, those of 1986 and 1987. The limited information available indicated that the 1988 yearclass is below average, and is currently estimated to be about the level of the weak 1983 and 1984 year classes.

The biomass decline described by ADAPT is not as steep as that indicated by the RV index alone. The retrospective analysis suggested that large changes in RV indices are not reflected to the same degree in the estimated population from ADAPT as is the case for the L/S. If the 1991 survey is considered to accurately represent the current stock status, the results from the L/S analysis are likely more representative. If the large changes in the RV indices include a year effect, as was the case with the 1986 survey, then ADAPT would provide a more appropriate estimate. The information available from the commercial fishery in 1992, as well as additional surveys (scouting, acoustic) suggest that the 1991 survey may be representative of stock status. However, the discrepancy between 1990 and 1991

data, especially with regard to the decline in abundance of older fish has not been accounted for.

^aA/L key used was a combination of 2J and 3K qtr. 4 OT keys.
^bIncludes French landings for 2J (84 t).

^cA/L key used was a combination of qtrs. 1 and 2.

^dLT age composition was obtained using the age composition of other inshore fixed gears combined.

^eA/L key used was a combination of qtrs. 1 and 2.

^fA/L key used was a combination of qtr. 3 GN(o) and qtr. 3 OT.

^gA/L key used was qtr. 4 OT.

^hThe reported catch with an estimate of 4000 t misreported from 3NO removed.

ⁱAge composition for LL(1238 t) was obtained using the age composition of other inshore fixed gears combined.

^jEstimate of foreign catch on the "Nose" as obtained from surveillance.

^kA/L key from Can(N)-3L qtrs. 1 and 2 was used.

^lAn A/L key from the Can(N) spring research vessel survey in 3L was used.

Table 46. Input parameters for projections for 2J3KL cod.

Age	Jan. 1 1992		Weight at age (kg)	Partial Recruitment	
	Population Nos.(000)	L/S		ADAPT	L/S
3	270,000	250,000	0.42	.017	.012
4	141,310	132,375	0.68	.14	.12
5	315,586	268,601	1.02	.40	.35
6	132,035	83,953	1.45	.70	.63
7	32,065	17,164	1.88	1.0	1.0
8	10,766	5,326	2.19	1.0	1.0
9	5,182	1,500	2.57	1.0	1.0
10	3,787	827	3.07	1.0	1.0
11	1,676	450	3.78	1.0	1.0
12	404	116	5.02	1.0	1.0
13	273	36	6.41	.50	.50
14	190	58	8.45	.50	.50
15	0	0	10.47	.50	.50

Table 47. Results of projections to 1992 for 2J3KL cod.

RESULTS FROM ADAPT STARTING VALUES			
1992 Catch (000t)	1992 F (Ages 7-9)	1993 Jan 1 3+ Biomass (000t)	1993 Jan 1 7+ Biomass (000t)
79	0.25	781	222
100	0.33	758	209
145	0.50	712	182

RESULTS FROM LAUREC/SHEPHERD STARTING VALUES

1992 Catch (000t)	1992 F (Ages 7-9)	1993 Jan 1 3+ Biomass (000t)	1993 Jan 1 7+ Biomass (000t)
50	0.25	658	134
94	0.50	612	112
100	0.54	607	109
145	0.84	560	112
