## Status report for northern Labrador Arctic charr stocks in 1993

## by

J.B. Dempson and M. Shears Science Branch
Department of Fisheries and Oceans
P.O. Box 5667

St. John's, Newfoundland A1C 5X1
${ }^{1}$ This series documents the scientific basis for the evaluation of fisheries resources in Atlantic Canada. As such, it addresses the issues of the day in the time frames required and the documents it contains are not intended as definitive statements on the subjects addressed but rather as progress reports on ongoing investigations.

Research documents are produced in the official language in which they are provided to the secretariat.
${ }^{1}$ La présente série documente les bases scientifiques des évaluations des ressources halieutiques sur la côte atlantique du Canada. Elle traite des problèmes courants selon les échéanciers dictés. Les documents qu'elle contient ne doivent pas être considérés comme des énoncés définitifs sur les sujets traités, mais plutôt comme des rapports d'étape sur les études en cours.

Les Documents de recherche sont publiés dans la langue officielle utilisée dans le manuscrit envoyé au secrétariat.

## Abstract

Catch and effort statistics for the northern Labrador Arctic charr fishery in 1993 are summarized. Total northern Labrador charr landings of $38 t$ were the lowest on record since 1974 and 66\% below the previous 10-year mean of $112 t$. Charr landings from the Nain fishing region totaled $34 t$ or $88 \%$ of the northern Labrador catch. Within the Nain fishing region, effort among all stock units was similarly the lowest recorded. Catch rates in all stock units were generally low, but lower values have occurred in previous years. Landings of Arctic charr in the Nain assessment unit during 1993 represented $40 \%$ of the overall catch from the Nain fishing region, while the Voisey unit contributed 25\%. Charr landings from the Hebron and Saglek fiord subareas contributed $26 \%$ of the Nain region catch. Information on timing of the fisheries, catch- and weight-at-age along with an index of condition are provided for the three main stock units to complement previous studies. Some comments from local fisherpersons are also included.

## Résumé

On présente un sommaire des statistiques sur les prises et l'effort de pêche de l'omble chevalier dans le nord du Labrador en 1993. Les débarquements totaux pour cette région, soit $38 t$, sont les plus bas enregistrés depuis 1974 et sont inférieurs de 66 \% à la moyenne des dix dernières années (112 t). Les débarquements d'omble chevalier provenant de la zone de pêche de Nain s'établissaient à $34 t$, ce qui représente 88 of des prises de tout le nord du Labrador. Dans la zone de Nain, l'effort dans toutes les unités de stock était le plus bas enregistré à ce jour. Les taux de prises étaient généralement faibles dans toutes les unités de stock, mais on en a connu de plus bas antérieurement. En 1993, les débarquements d'omble chevalier de l'unité d'évaluation de la baie de Nain représentaient $40 \%$ des prises totales de la zone de pêche de Nain, tandis que celles de l'unité d'évaluation de Voisey représentaient $25 \%$ du total. Les débarquements d'omble chevalier provenant des secteurs des fjords Hebron et Saglek constituaient $26 \%$ des prises de la zone de pêche de Nain. Pour compléter les études antérieures, on présente également des renseignements au sujet de la période à laquelle se déroule la péche, des prises et du poids selon l'age, ainsi qu'un index des conditions dans les trois principales unités de stock. Sont aussi incluses les observations de certains pêcheurs de la région.

## Introduction

Continuous records of commercial landings of anadromous Arctic charr (Salvelinus alpinus) from the northern Labrador coast are available since 1944. Catch statistics from the Nain and Makkovik Fishing Regions, and from subareas within the Nain Fishing Region (Fig. 1) exist since 1974. From 1977 to 1982 more than 200 t per year of Arctic charr were caught in northern Labrador but during the previous five years (1988-92) annual landings averaged only 87 $t$. The highest landings on record were 252 t in 1981. The lowest landings during the past 30 years were 38 t and occurred in the most recent year, 1993. Much of the decline in landings in the Nain fishing region during the past eight years can be attributed to a reduction in fishing effort. However, recent assessments of the Voisey and Nain stock units have also indicated that current stock sizes were below levels estimated for the late 1970's and early 1980's (Dempson 1992, 1993a). Recently, the Labrador Inuit Association (LIA) has explored the feasibility of developing inriver fisheries for Arctic charr in some of the northern fiord subareas. These fisheries could provide selective harvests on some charr stocks while at the same time providing an opportunity for a direct evidence of actual spawning escapements.

This paper summarizes catch statistics information for the 1993 northern Labrador Arctic charr fishery and updates previous reports (summarized in Dempson and Shears 1991, 1992, and Dempson 1993a) which have examined landings in the commercial fishery.

## Methods

Information on commercial landings of Arctic charr from the Nain fishing region was obtained through purchase slips prepared by Fisheries Statistics and Systems Branch of the Department of Fisheries and Oceans and processed by Salmon and Charr Section of the Salmonid and Habitat Sciences Division. Information on landings from the Makkovik region were obtained directly from records provided by the Makkovik fish plant. Purchase slips from the Nain fishing region included the following information: name of the fisherperson, licence number, area where the fish were caught, date, weight of fish (by species) landed, and number of fish caught. Landed gutted head-on catches were converted to round weight (in kilograms) using the conversion factor: gutted head-on weight x $1.22=$ round weight (Dempson 1984). Catch per unit effort estimates in this document, expressed in terms of kilograms per person-week fished, follow the traditional values used in past reports and were derived from the method initiated by coady and Best (1976). These unstandardized values are included for comparative purposes with past reports.

A multiplicative model (Gavaris 1980) was used to standardize catch rates for each stock unit and account for differences among
years and weeks. For the Nain and Okak stock units, inshore and offshore zones were treated separately. These fisheries are carried out using shore-set surface gill nets, often in traditional fishing berths. The regression of $\ln$ catch rate for the period 1977 to 1993 was initially fitted using SAS REG procedures (SAS 1985) to avail of the various diagnostics available. Backtransformed standardized catch rates were subsequently obtained using a bias correction process also run in SAS.

Information on length, weight and age of Arctic charr caught in the commercial fishery was obtained as fish were processed at the Nain Fish Plant. A two-stage stratified sampling program was carried out. Samples are identified from individual subareas which form component parts of stock units (Dempson and Kristofferson 1987).

Analyses of condition were carried out following the general methods of Patterson (1992) and are fully described in winters and Wheeler (1994). A general linear model ( $\log _{e}$ transformed) was used to examine the response of fish weight, standardized to a common length, to various factors as:

$$
Y_{i j k}=\mu+\alpha_{i}+\beta_{j}+(\alpha \beta)_{i j}+b \cdot Z_{i j k}+\epsilon_{i j k} \text {, where }
$$

$Y_{i j k}=$ the response variable, charr weight (gutted, head-on), $\alpha_{i}$ and $\beta_{j}$ are class variables month and year, respectively, $(\alpha \beta)_{j k}$ is an interaction term between month and year, $Z_{i j k}$ is the covariate fork length, and $\epsilon_{i j k}$ is the error term associated with individual observations. With respect to the month variable, July refers to June and July, while August includes August and September. Charr caught in the commercial fishery are landed in the gutted form. This ensures that stomach fullness and gonadal development, if any, do not confound the interpretation of the overall index of condition. The model was used to calculate adjusted mean weights by year standardized to the covariate. Each stock unit was analysed separately. Analyses followed the sequential procedure described by Winters et al. (1993) and Winters and Wheeler (1994). Initially, analyses were used to determine the appropriate model, i.e., common slope (b) or multiple slope $\left(b_{i j k}\right)$. Intercept differences $(\mu)$ were tested based on class variable effects if a common slope model was appropriate. Interactions between month and year were examined to investigate the temporal distribution of condition for each stock over a period of 17 years.

## Results and Discussion

## Total northern Labrador Arctic charr landings

Figure 2 illustrates the commercial landings of Arctic charr from 1944 to 1993. Also shown are the landings from the Nain and Makkovik fishing regions since 1974. During the past 20 years, the Nain region has contributed about $85 \%$ of the total northern Labrador catch of Arctic charr averaging 122 t per year. Landings from both regions in 1993 totaled only $38 t$, and was $56 \%$ and $66 \%$ below the previous five ( 87 t , 1988-92) and ten year (112 $t$, 198392) means (Table 1). Individually, landings in the Nain fishing region of $34 t$ in 1993 were down $45 \%$ from 1992 and $54 \%$ and $64 \%$ below previous five ( $72 \mathrm{t}, 1988-92$ ) and ten year ( 94 t , 1983-92) means. The number of people fishing had been relatively consistent during the past few years (1990-92) but dropped considerably in 1993. Effort (unstandardized) in terms of person-weeks fished in 1993 was $28 \%$ less than in 1992 and was the lowest value recorded since 1974 (Appendix 1). It has declined by $70 \%$ from the 1981-85 average.

Undoubtedly, the extremely poor environmental conditions experienced along the north Labrador coast in 1991 contributed to the decreased effort and general failure of the fishery. Conditions in 1992 were, for the most part, similar to 1991. The 1993 season was also characterized by a late spring. A limited commercial fishery occurred in the Hebron and Saglek fiords in 1993 with landings totaling $9 t$ and contributing $26 \%$ of the Nain region catch of Arctic charr. An experimental in-river fishery slated again for Southwest Brook, Saglek Fiord, did not proceed. In 1992, the experimental fishery at Saglek harvested 2.2 t of charr. This represented $28 \%$ of the total number of commercial sized charr (fish $>45 \mathrm{~cm}$ ) that entered the river during the 18 days of the fishery (August 3-20), but only $4 \%$ of the entire run enumerated during that period ( $\mathrm{N}=31687$ ) (Dempson 1993a).

A summary of harvests from specific experimental river fisheries carried out in the Nain fishing region are provided in Table 2.

Charr landings from the Makkovik region in 1993 decreased by 64\% from the previous year and totaled only $5 t$. The highest landings in the Makkovik region of $39 t$ occurred in 1982. Concern has been expressed about low catches and the amount of small charr being caught at Makkovik, Postville, and Hopedale (Unpublished Annual Report by Fishery Officer Eric Andersen, Makkovik, Labrador). Concerns pertain equally to the local food fisheries for charr.

Appendix 1 provides an updated summary of catch and effort statistics for all subareas within the Nain fishing region from 1974 to 1993 (experimental harvests are not included in the
appendix - refer to Table 2). Some of these subareas form component parts of larger assessment or stock units. The Nain fishing region is composed of three primary assessment units (Voisey, Nain, and Okak) in addition to other subareas which are not, at present, component parts of larger assessment units or stock complexes. These primary assessment units have contributed an average of $80 \%$ of the commercial production of Arctic charr from the Nain fishing region over the period 1974-91.

## Voisey Stock Unit

## V. 1 Commercial landings and catch rates

The Voisey stock unit is made up of Voisey Bay and the Antons subareas (Fig. 1). Annual landings have ranged from 4 to 41 t (mean $=19 t$, 1974-93), and over this interval have contributed 16\% of the commercial catch of charr from the Nain fishing region (Table 3). The highest catches occurred during the late 1970's (Fig. 3), the lowest catch of 4 t was in 1975. The Total Allowable Catches (TAC) listed in Table 3 for 1979 to 1984 applied only to the Voisey Bay subarea. The recommended TAC in 1993 was maintained at 14 t.

Landings of Arctic charr from the Voisey assessment unit during 1993 totaled $8.5 t$, $60 \%$ of the Total Allowable Catch (TAC), and represented $25 \%$ of the overall catch from the Nain fishing region during 1993 (Table 3). This was a decline in the stock unit catch of $9 \%$ from the previous year. Effort, however, increased by about $23 \%$ yielding the lowest unstandardized catch rate on record.

With respect to the standardized catch rates, the regression of $\ln$ catch rate for the period 1977-93 explained $48 \%$ of the variation in the data. Highest catch rates occurred in the late 1970's, 1983, and again in 1989-90 (Fig. 3). Even in 1992 the catch rate was moderately high. The catch rate in 1993, however, was the third lowest recorded. Generally catch rates are highest during weeks 30-32 (July 23- August 12) in addition to week 25 (June 18-24). Standardized effort has been among the lowest recorded in 1992 and 1993 (Table 4).

## V. 2 Timing of the fishery

Normally, peak runs of Arctic charr to rivers in the Nain area occur during early August (Dempson and Green 1985). Variability in catches and catch rates must also be considered in the context of run timing to local rivers. This is because some or many fish could potentially not be available for capture depending upon the timing of the commercial fishery. Figure 4 illustrates the timing of the fishery for the Voisey stock unit from 1977-93. The median date of the catch ( $50^{\text {th }}$ percentile) from 1977-90 was day 199 (July
18). Landings in 1991 were about one week later than this average, but catch timing during the past two years has been similar to the mean.

## V. 3 Catch at age

Catch at age data are available since 1977 (Table 5). Typically, four age classes (ages 7-10) make up $85 \%$ of the catch. Charr are first recruited into the fishery at age 6 and ages over 12 contribute little. The 1985 and 1986 year classes (year of hatching) represented by 7 and 8 year old fish were the most abundant in 1993 contributing 58\% of the catch. On a proportional basis, age 6 and 7 fish in 1993 were among the highest represented. Mean age of the catch has ranged from a high of 9.3 years in both 1990 and 1991 to a low of 8.0 years in 1993. In general, mean age of the catch has varied little over time (mean $=8.8 \mathrm{yrs}$, coefficient of variation (CV) $=4.1 \%$ ).

Analytical sequential population analyses were not carried out on the most recent data. As noted above, effort during the past several years has been among the lowest recorded and thus there is little basis for an adequate catch rate series from which to calibrate the sequential population analyses.

## V. 4 size at age and condition

Weights at age were derived from length-weight relationships obtained from sampling the commercial fishery as explained in past years (Dempson 1990). A comparison of the recorded total landings for 1993 with the cross product total (sum of the matrix of estimated numbers at age $x$ matrix of weights at age) agreed quite well with the discrepancy between the two of about $0.3 \%$. As identified in previous years, weights at age have declined over time (Table 6). Part of the reason for the overall decline in mean weight in 1993 relates to the high proportion of age 6 and 7 fish ( $44 \%$ ) in the catch in comparison with previous years.

Analysis of condition by the weight-length relationship indicated that slopes were significant although in comparison with the common slope model, the reduction in the residual (error) mean square was negligible ( $2 \%$ ) with $r^{2}$ values virtually identical. Excluding fork length, $88 \%$ of the remaining variation in the model is accounted for by the main effects. Thus a common slope model was used in further comparisons of intercept differences due to class variable effects. All main effects were significant (Table 7) as was the interaction between year and month. Condition of charr caught in August is greater than those caught in July. Lowest condition has been in the early 1990 s and as well for July, in 1985 and 1986 (Fig. 5). Condition has been used as an index of annual growth success (eg. Winters and Wheeler 1994).

Notwithstanding the low estimates for July 1985 and 1986, the low condition values in the early 1990s, which have also observed in the other stock units (Fig. 5), could be suggestive of a commonality of various proximate factors (temperature, food availability, etc.) that have contributed to this apparent pattern.

## Nain Stock Unit

## N. 1 Commercial landings and catch rates

The Nain stock unit consists of an inshore zone made up of Anaktalik Bay, Nain Bay, Tikkoatokak Bay, and Webb Bay subareas, and an offshore island zone made up of the Dog Island and Black Island subareas (Fig. 1). Annual landings have ranged from 13 to 76 t (mean $=47 \mathrm{t}$, 1974-93), and over this interval have contributed $41 \%$ of the commercial catch of charr from the Nain fishing region (Table 8). The highest catches occurred during the late 1970's and early 1980's (Fig. 6), with the lowest catch of 13 $t$ in 1993. The TACs listed in Table 8 for 1979 to 1983 applied to the specific subareas of Anaktalik Bay and Nain-Tikkoatokak Bay only. In 1984 and 1985, an offshore component was included in the TAC. The quota area catch (QAC) in Table 8 summarizes landings for those subareas specifically under quota restrictions only, prior to the derivation of the stock units in 1986. Since 1986, the TAC has applied to the entire stock unit.

Science advice for 1993 recommended a reduction in the reference level catch from 47 t to 32 t . However, the management plan for 1993 maintained the TAC at 47 t.

Landings of Arctic charr from the Nain assessment unit during 1993 totaled $13.4 t$, only $29 \%$ of the TAC (or $42 \%$ of the recommended level), but represented $40 \%$ of the overall catch from the Nain fishing region during 1993 (Table 8). This was a decline in the stock unit catch of $31 \%$ from the previous year. Effort also decreased by $11 \%$ yielding one of the lowest unstandardized catch rates recorded. A summary of landings partitioned by inshore and offshore fishing zones is presented in Table 9.

With respect to the standardized catch rates, separate analyses were done for inshore and offshore fishing zones. For the inshore zone, the regression of ln catch rate for the period 197793 explained $69 \%$ of the variation in the data. Highest catch rates occurred in the late 1970's and early 1980's and have generally declined over time (Table 10, Fig. 6). Catch rates were highest during weeks 31-33 (July 30-August 19). Since 1991, catch rates have been the lowest recorded. Standardized effort in 1993 was also the lowest recorded (Table 10).

For the offshore zone, the regression of in catch rate for the period 1977-93 explained $73 \%$ of the variation. Highest catch rates also occurred during weeks 31-33 (July 30-August 19) and generally increased until around 1990 (Table 10, Fig. 6). The catch rate in 1993, while 35\% less than the 1984-90 average, was still 31\% greater than the 1977-83 average. Standardized effort was the lowest recorded in 1992 and 1993 (Table 10).

The Nain stock unit is where the domestic or spring food fishery largely occurs. This fishery is targeted on charr as they migrate to sea. Efforts in the past, both by DFO and more recently by the Labrador Inuit Association, have failed to quantify the amount of charr taken annually in this food fishery. This unaccounted for harvest has not been factored into the commercial landings or catch at age estimates. Removals from the spring food fishery could be more significant during the past three years (1991-93) when overall commercial landings have averaged only 16 t• $y^{-1}$ in contrast to the 1977-90 period when commercial landings averaged over $54 t \cdot y^{-1}$. In recent years, the LIA has expressed concern about this fishery.

## N. 2 Timing of the fishery

Figure 4 illustrates the timing of the fishery for the Nain stock unit from 1977-93. The median date of the catch from 1977-90 was day 207 (July 26). Landings in 1991 were three weeks later than this average (median day 229, August 17), while in 1992 landings were about four weeks later (day 234, August 22) and compressed over a rather short interval (Fig. 4). The 1993 fishery was two weeks later (median day 220, August 8) than the 14 -year (1977-90) average.

Further insight can be gained by examining the timing within the respective inshore and offshore fishing zones (Fig. 7). On average over the 14-year period 1977-90, the median timing of the catch in the offshore zone was about 14 days later than the inshore zone. With respect to the inshore zone, median timing of the 1991-93 fisheries have been 21 to 31 days later than the 1977-90 average. For the offshore zone, timing in 1991 and 1992 was about 2 weeks later, but for 1993 the median date of the catch was actually 6 days earlier (Fig. 7).

## N. 3 Catch at age

Catch at age data are available since 1977 (Table 11). Typically, four age classes (ages 7-10) make up 82\% of the catch. Charr are first recruited into the fishery at age 6 and ages over 12 contribute little to the fishery. The 1984 and 1985 year classes (year of hatching) represented by 8 and 9 year old fish were the most abundant in 1993 contributing $54 \%$ of the catch.

These year classes appear to follow through from their strong contributions in 1992. Mean age of the catch has ranged from a high of 9.8 years in 1982 to a low of 8.5 years in 1977. In general, mean age of the catch has varied little over time ( $\bar{x}=9.1$ yrs, $C V=4.1 \%$ ).

Sequential population analyses were not carried out on the most recent data. As noted above, effort in 1993 has been among the lowest recorded and thus there is little basis for an adequate catch rate series from which to calibrate the sequential population analyses.

## N. 4 size at age and condition

Weights at age were derived from length-weight relationships obtained from sampling the commercial fishery as explained in past years (Dempson 1990). A comparison of the recorded total landings for 1993 with the cross product total (sum of the matrix of estimated numbers at age $x$ matrix of weights at age) agreed quite well with the discrepancy between the two of about 0.1\%. As identified in previous years, weights at age have declined over time (Table 12). Part of the reason for the overall decline in mean weight in recent years could be directly related to the timing of the fishery. As noted earlier, larger charr return to the rivers first with fish returning to freshwater as early as the second week of July (Dempson and Green 1985). This is further illustrated in Figure 8 which shows the change in size composition of Arctic charr returning to Ikarut River over the summer. During the past several years, the median timing of the Nain stock unit fishery has been up to three and four weeks later in comparison with 'average' timing over a 14 -year period.

In addition to the timing of the fishery, several other factors may have contributed to the smaller size of fish in the catch. With the decline in the catch of salmon at Nain in recent years ( $\bar{x}=20 \mathrm{t}, 1985-89$, versus $\bar{x}=2.4 \mathrm{t}, 1991-93$ ), there has been proportionally more 114 mm mesh gill nets used rather than both 114 and 127 mm mesh nets. In the later part of August, some gear has been set close to river mouths in some bays. When set in these locations where there is a strong influence of both tide and river current, the nets are stretched more and are effectively fishing as a smaller mesh gear. For the 1993 fishing season, the local fish plant was also instructed to accept charr that were within the $0.45-0.91 \mathrm{~kg}$ weight range (1-2 pound). Typically in the past, charr less than 0.91 kg were not accepted. This, however, should not be a major factor. Several questionnaire surveys conducted in past years with local fisherpersons indicated that few charr of this size were actually caught. This was also apparent in DFO research sampling carried out in 1978-80 with various mesh size gear. For the Nain stock unit in 1993, Arctic charr in the 0.45-
0.91 kg category made up only $3.9 \%$ of the catch (4.1\% at Voisey, 0\% at the Okak unit).

Analysis of condition indicated that slopes were also significant for the Nain stock unit although again in comparison with the common slope model, the reduction in the residual (error) mean square was minimal (3\%) with $r^{2}$ values virtually identical. Excluding fork length, $83 \%$ of the remaining variation in the model is accounted for by the main effects. Thus a common slope model was used in further comparisons of intercept differences due to class variable effects. All main effects were significant (Table 7) as was the interaction between year and month. Condition of charr caught in August is again greater than those caught in July. Similarly, the lowest condition values have been recorded during recent years (Fig. 5).

## Okak Stock Unit

### 0.1 Commercial landings and catch rates

The Okak stock unit consists of an inshore component made up of Okak Bay and an offshore island zone made up of the cutthroat subarea (Fig. 1). Annual landings have ranged from only 180 kg in 1992 to a high of $76 t$ in 1978 (mean $=29 t, 1974-93$ ), and over this interval have contributed $21 \%$ of the commercial catch of charr from the Nain fishing region (Table 13). The highest catches occurred during the late 1970's and early 1980's (Fig. 9), with the lowest catches during the past two years. The Total Allowable Catches (TAC) listed in Table 13 for 1981 to 1985 applied only to the Okak Bay subarea. The recommended TAC in 1993 was maintained at 31 t.

Landings of Arctic charr from the Okak assessment unit during 1993 totaled 0.6 t. For the past two years, no fishing has been carried out within Okak Bay itself and virtually no effort has been directed to the offshore cutthroat subarea. Families that had traditionally fished this stock unit no longer participate in the fishery and have not done so for the past several years.

With respect to the standardized catch rates, separate analyses were done for inshore and offshore fishing zones. For the inshore zone, the regression of ln catch rate for the period 197791 explained 64\% of the variation in the data. Highest catch rates occurred in the late 1970's and early 1980's with a moderately high value in 1990 (Table 14, Fig. 9). Catch rates were also highest during weeks 31-33 (July 30-August 19). The lowest catch rates were in 1985, 1988 and 1989. The low effort in 1981, 1982 and 1984 was directly related to the expanded fisheries in the northern fiord subareas of Hebron and Saglek. The low catch in 1991 was related to the low directed effort in Okak Bay.

For the offshore zone (Cutthroat), the regression of ln catch rate for the period 1977-93 explained 75\% of the variation. Highest catch rates also occurred during weeks 31-33 (July 30August 19). Catch rates were highest again in the late 1970's and early 1980's but have been generally quite variable over the entire sequence of years (Table 14, Fig. 9). With the extreme low landings and effort in the past several years, interpretation of the commercial catch rate series as an index of abundance is questionable.

### 0.2 Timing of the fishery

Figure 4 illustrates the timing of the fishery for the Okak stock unit from 1977-93. The median date of the catch from 1977-90 was at day 222 (August 10). While landings in 1991 were about 9 days later than this average (median day 231, August 19), the 1992 and 1993 fisheries, albeit rather limited, occurred earlier than the median date (Fig. 9). In general, the median date of the catch in Okak Bay occurred about a week and a half after that at Cutthroat and reflects the former pattern of availing of the salmon by-passing the Cutthroat area before moving into Okak Bay to intercept the run of charr back to the rivers.

### 0.3 Catch at age

Catch at age data are available since 1977 (Table 15). Until about 1988, four age classes (ages 8-11) made up 77\% of the catch. This declined to about 71\% in 1989-91. The youngest charr caught in the Okak fishery are age 6 but these are generally few in number. Okak charr age distribution is generally more variable than the Voisey or Nain stock units and the mean age of the fish is often older. As indicated above, there has been virtually no fishery in the Okak stock unit during the past two years. Estimated numbers at age may not be representative for 1992 and 1993 as sampling was rather sparse. Data are included, however, for completeness.

Analytical sequential population analyses have not carried out on the okak stock unit in recent years. Calibration attempts in past years were the least successful for the Okak unit. The limited effort directed towards the okak unit since 1991 precluded any attempts to estimate stock size using rigorous analytical sequential population models.

## 0.4 size at age and condition

Weights at age were derived in a manner consistent with the other stock units. A comparison of the recorded total landings with the cross product total (sum of the matrix of estimated
numbers at age $x$ matrix of weights at age) has agreed quite well in the past with the discrepancy between the two of less than $0.6 \%$, for example for 1989-91. Weights at age have been more consistent than in the other two major stock units, and have not experienced the same degree of declined over time (Table 16). The limited data for 1992 and 1993 preclude any comment of events in recent years.

Analysis of condition indicated that slopes were significant for the Okak stock unit. Again, however, in comparison with the common slope model, the reduction in the residual (error) mean square was minimal ( $<2$ \%) with $r^{2}$ values virtually identical. Excluding fork length, $90 \%$ of the remaining variation in the model is accounted for by the main effects. Thus a common slope model was used in further comparisons of intercept differences due to class variable effects. All main effects were again significant (Table 7) as was the interaction between year and month. Consistent with the other stock units, condition of charr caught in August is again greater than for charr caught in July. The lowest condition indices recorded for August have been in 1992 and 1993. Similarly, lowest condition values for July have occurred in 1992 but also in 1984 and 1985 (Fig. 5).

## Conclusions

Much of the decline in Arctic charr landings in the Nain fishing region during the past eight years can be attributed to a continued decline in effort directed towards the fishery. As acknowledged earlier, assessments of several of the stock units have also indicated that stock sizes have also declined over time and were below levels during the late 1970's and early 1980s. This in itself could also have contributed to the trend for diminished landings. Stock sizes were estimated using sequential population analyses (SPA) calibrated with commercial catch rate information. The latter may not be entirely appropriate as a calibration tool. Particularly in recent years, effort has been extremely low and thus the spatial coverage of fishing may be insufficient to draw conclusive results with respect to overall stock abundance. It has also been pointed out in the past that independent estimates of stock size were not available either to calibrate SPA runs, or to provide actual census information on current stock sizes returning to north Labrador rivers (Dempson 1993b).

Some local fisherpersons at Nain have indicated that part of the reason for the low abundance of charr in 1993 was due to a lack of snow during the past winter (Norm Andersen, DFO Fisheries Officer, Nain, Labrador, personnel communication). The absence of snow made the spring run-off virtually non-existent. These fisherpersons thus concluded that many charr did not migrate to sea in 1993. Without census information on specific rivers, this 'hypothesis' could not be addressed, but is noted as a valid comment from local individuals. Comments from fisherpersons have
also included reference to a noticeable absence of local bay capelin stocks. Some fisherpersons at Nain believe that this is a contributing factor for charr not remaining within the inner bay areas during the past $8-10$ years. This is consistent with observations on the distribution of tag recaptures with more returns from the offshore zone, and the change in catch rates from inshore and offshore fishing zones of the Nain stock unit.

The salmon licence buy-out was extended to north coastal fisherpersons in August of 1993. This has effectively removed a number of fisherpersons from actively participating in subsequent years as the 'buy-out' considered both commercial charr and salmon fishing. It is expected that the Nain stock unit will continue to receive most of the directed effort in subsequent years a fact also acknowledged by the Nain fisherpersons committee. This is due to the importance of the spring food fishery, particularly at Nain Bay, and the proximity of this entire stock unit to the local fish plant; collector boats are not necessary. Viable fisheries directed towards Arctic charr are still possible in northern Labrador. Fisheries occurring within the inner bays and fiords will, for the most part, intercept few salmon. Many of the areas to the north of Okak Bay are underutilized. Fisheries in these areas have not been undertaken on a continuous basis and could conceivably provide alternatives for rotational fisheries or riverspecific harvesting programs.

It is suggested that the advice supplied for the 1993 fishery be implemented for 1994. Specifically, this called for a $30 \%$ reduction in the reference level catch for the Nain stock unit with the Voisey and Okak units remaining as in 1993. Future fisheries will differ from the intense harvesting levels experienced in the past. Emphasis on quality rather than quantity has been a concern and has been partially addressed by conducting experimental inriver fisheries. To date, there is continued interest in the latter.

For 1985, Makkovik Region, catch includes 6788 kg from spring fishery in Postville area.
Catch for Nain Fishing Region includes in-river harvest in 1989, 1991, and 1992, and the trap net
fishery at Nachvak Fiord in 1986.

Table 8. Catch (kg) and effort (person-weeks) statistics for the Nain assessment unit from 1974 to 1993. Quota area catch (QAC) refers to the landings from those subareas specifically under TAC regulation only, prior to the derivation of assessment units in 1986. CUE is unstandardized.

| Year | TAC | QAC | Catch | Effort | CUE | \% <br> Offshore | Unit as \% of Nain Region Total |

| Avg. 1974-93 |  | 46809 |  |  |  |  |  |

TAC applied only to Anaktalik Bay and Tikkoatokak Bay from 1979 to 1983 (1983 also includes 5 t for Nain Bay) but includes an offshore component from 1984 to 1985.

Table 9. Summary of catch and effort statistics for the Nain stock unit, 1974-93. Quotas and landings are in kg round weight, effort is expressed as person-weeks fished. Refer to text for information on quotas and quota area catch. CUE = unstandardized catch per unit effort.
