# Georges Bank Cod and Haddock Ageing Exchange and Workshop November 8-10, 1993 

by
L. Van Eeckhaute and M.-I. Buzeta

Department of Fisheries and Oceans
Biological Station
St. Andrews, New Brunswick
and
Nancy Munroe and Vaugin Silva
National Marine Fisheries Service
Northeast Fisheries Science Center
Woods Hole, Massachusetts. USA

This series documents the scientific tasis for the evaluation of fisheries resources in Atlantic Canada. As such, it addresses the issues of the day in the time frames required and the documents it contains are not intended as definitive statements on the subjects addressed but rather as progress reports on ongoing investigations.

Research documents are produced in the official language in which they are provided to the secretariat.
'La présente série docunnente les bases scientifiques des évaluations des ressources halieutiques sur la còte alantique du Canada. Elle traite des problemes courants selon les èchéanciers dictés. Les documents quelle contient ne doivent pas être considérés comme des énoncés définitiff sur les sujets traités, mais plutót connme des rappons detape sur les ćades en cours.

Les Documents de recherche sont publies dans la langue officielle utilisée dans le manuscrit envoyé au secrétariat.

#### Abstract

Age readers from the St. Andrews Biological Station at St. Andrews, N.B. and the Northeast Fisheries Science Center at Woods Hole, Massachusetts participated in an ageing workshop to discuss results of exchanges of Georges Bank cod and haddock ageing material. The objectives were to document interlab comparison readings of cod otoliths and haddock otoliths and scales and to discuss specific characteristics of otoliths which caused discrepancies in age assignments.

For cod, discussions included edge type assignment and double/split annuli. Agreement in age assignment between the two labs was satisfactory ( $89 \%$ ) and reflects previous results.

Agreement between Canadian and USA reader's age assignments for haddock otoliths was $90 \%$ for the 1992 Canadian research survey and $86 \%$ for 1993 Canadian commercial samples. Agreement for scales versus otoliths, as assigned by the USA age reader, for the same samples was $75 \%$ and $76 \%$ respectively and a bias toward underageing by scales was observed.

Workshop participants agreed that a maximum of 100 otoliths per year should be exchanged, and that seasonality should be incorporated into sample selection. Recommendations included the continuation of workshops on alternate years and that the USA lab assess the magnitude of the scale underageing bias on their haddock survey and commercial catch age structures.

## RÉSUMÉ

Les spécialistes de la détermination de l'âge de la Station de biologie de St. Andrews (N.-B.) et ceux du Northeast Fisheries Science Center de Woods Hole, au Massachusets, ont participé à un atelier sur la détermination de l'âge de la morue et de l'aiglefin du banc Georges, au cours duquel ils ont discuté des résultats de leurs échanges de données à ce sujet. L'atelier en question avait pour but de documenter les lectures comparatives des otolithes de morue et d'aiglefin ainsi que des écailles d'aiglefin réalisées par les deux laboratoires et de traiter des caractéristiques particulières des otolithes qui sont à l'origine d'erreurs dans l'attribution des âges.

En ce qui a trait à la morue, il s'agissait de discuter de certaines notions comme les types de bord et le dédoublement des anneaux. La concordance dans l'attribution des âges entre les deux laboratoires était satisfaisante ( $89 \%$ ) et conforme aux résultats antérieurs.

Quant à la concordance entre les chercheurs canadiens et américains dans l'attribution des âges d'après les otolithes de l'aiglefin, elle était de $90 \%$ sur le relevé de recherche canadien de 1992 et de $86 \%$ sur les échantillons commerciaux canadiens de 1993. La concordance entre la lecture des écailles et celle des otolithes par les spécialistes américains s'établissait respectivement à $75 \%$ et $76 \%$ sur les mêmes échantillons et on a observé une tendance systématique à la sous-estimation dans la détermination de l'âge d'après les écailles.

Les participants ont convenu d'échanger un maximum de 100 otolithes par an et de tenir compte de la saisonnalité dans le choix de l'échantillon. Les recommandations formulées portaient notamment sur la poursuite des ateliers tous les deux ans et sur la nécessité pour le laboratoire américain d'évaluer l'importance de la tendance à la sous-estimation dans le relevé de recherche sur l'aiglefin et dans les structures d'âge des prises commerciales de ce poisson.

## INTRODUCTION

A conclusion of the 1991 Georges Bank cod (Gadus morhua) and haddock (Melanogrammus aeglefinus) ageing workshop was to continue a yearly exchange of age material between age readers at the Biological Station in St. Andrews, N.B. and the Northeast Fisheries Science Center at Woods Hole, Mass. and to document results (Buzeta et al. 1992). Age readers from St. Andrews and Woods Hole exchanged ageing material collected during 1992 and 1993 from Georges Bank cod and haddock. This exchange was followed by an age reading workshop at Woods Hole on October 8-10, 1993. The objectives of the exchange and workshop were to document comparison readings by the labs and to provide a venue whereby age readers could discuss specific characteristics of otoliths which caused discrepancies in age assignments.

## I. GEORGES BANK COD

Participants:
Nancy Munroe, NEFSC, Woods Hole, Mass.
Vaughn Silva, NEFSC, Woods Hole, Mass.
Maria-Ines Buzeta, Biological Station, St.Andrews, N.B.
The assignment of fish age following the Canadian convention utilizes the otolith's edge type and width to determine whether or not that edge is to be counted as an annulus. The USA convention includes the edge as an annulus during the first two quarters and does not do so in the last two quarters. This difference in convention was first discussed at the 1991 ageing workshop (Buzeta et al 1992). Incompatible interpretations of edge characteristics therefore could cause discrepancies between Canadian and USA age assignments.

A double or split annulus is described by Penttila and Dery (1988) as having a discontinuity or check causing the annulus to appear as two closely spaced hyaline zones. When this occurs at the otolith edge, it is difficult to ascertain whether it represents two years of growth or a single year's interrupted growth pattern. While a split may occur in other annuli, it is most frequently seen in the second year. This feature is of interest as a possible indicator of first spawning or as an aid in identification of the second annulus. Incorrect identification of this feature can potentially change the age assignment by 1 year.

## METHODS

One cod otolith from each of 90 pairs collected during the 1993 USA spring survey (93-04) was sent to the Canadian ager in August 1993. These were prepared and read according to Canadian procedures (Strong et al.1985) and the ages were subsequently compared to those assigned earlier by the USA ager. USA procedures are documented in Pentilla and Dery (1988). Disagreements in age assignments, including edge type, were discussed during this workshop.

Sixty-three otoliths from the 1993 Georges Bank spring groundfish survey (T134) and 20 otoliths
from the 1992 commercial samples, which were determined by the Canadian age reader as exhibiting a double/split second annulus, were examined by the USA age readers. Notes were made for each otolith regarding the detailed characteristics of a double/split second annulus.

## RESULTS

Age assignments by the USA and Canadian age readers for the otolith exchange are presented in Table 1. Agreement between age readers, where ages were assigned by both age readers, was $89 \%$ (Table 2). Of the 10 disagreements, 7 were aged as older by the Canadian age reader. Four of the disagreements occurred where otoliths were assigned age 3 by the USA age reader and age 4 by the Canadian age reader. Six of the disagreements were associated with edge type assignment, and the remainder were associated with checks and otoliths of poor reading quality.

After examining 82 of the otoliths which exhibited a double/split annulus only 3 were reassigned an age because of this feature. Although age readers agreed on the presence of a continuous second annulus ( $96 \%$ ), agreement as to what defined a double/split annulus versus a wide or a checky second annulus was very low (52\%).

## CONCLUSIONS

Agreement between the USA/Canadian age readers was considered satisfactory as it reflects the 1992 exchange results. It was agreed that the assignment of edge types should be carefully evaluated.

Recognition of a second annulus as a single annulus, even though it may exhibit a split, a wide band or several checks, was not considered a problem during age assignment.

It was agreed that a "double/split" annulus by definition must show a measurable opaque zone between two closely spaced hyaline zones.

## II. GEORGES BANK HADDOCK

Participants:
Nancy Munroe, NEFSC, Woods Hole, Mass.
L. Van Eeckhaute, Biological Station, St.Andrews, N.B.

The Canadian lab has traditionally used otoliths to age haddock. For haddock sampled from surveys, the USA lab routinely used scales but did use otoliths for fish $>65 \mathrm{~cm}$ from 1963 to 1984 and for fish $>50 \mathrm{~cm}$ since 1991. Scales exclusively were used from 1985 to 1990. Very few samples from the USA commercial haddock fishery have been aged using otoliths and scales still predominate.

The objectives of this exchange originate from recommendations made at the previous workshop (Buzeta et al. 1991): 1) that the USA lab re-examine the use of otoliths to age larger haddock, 2)
that the effect of geographic origin of the sample on scale ages should be examined and 3) that the USA ager read several otolith samples to compare with the Canadian ages to assess interlab agreement on otoliths. The workshop objective was to discuss criteria for assigning haddock ages to otoliths by the two haddock age readers.

## METHODS

To effect these recommendations both scale and otolith ageing materials for this workshop were taken from haddock which came from both the eastern and western portions of Georges Bank and from deeper waters off the bank. Otoliths and scales from 310 fish collected during the Canadian 1992 spring Georges Bank survey, N165, and 3 samples (104 otoliths) from the Canadian commercial fishery were exchanged. Otoliths were prepared by the method routinely used by each lab; the Canadian lab sections otoliths using the methods of Strong et al 1985, the USA lab cuts thin-sections using an Isomet low-speed saw (Penttila and Dery 1988).

Agreement was determined from independent readings of otoliths. Only the USA ager examined the scales.

During the workshop a double microscope was used to discuss otoliths from the N165 survey for which the assigned ages were in disagreement. When a consensus could not be reached for an individual age, other age readers at the lab were asked for their opinion. Canadian commercial fishery samples were not discussed due to time constraints.

## RESULTS

The levels of agreement where ages were assigned by both age readers, for the N165 survey otoliths (Table 3) and Canadian commercial samples (Table 4) were $90 \%$ and $86 \%$, respectively (Tables 5 and 6 ). However, of the 20 otoliths assigned age 6 by the USA reader (survey and commercial fishery samples combined), only 2 were assigned age 6 by the Canadian reader. These otoliths were assigned to either age 5 or 7 by the Canadian reader. Consensus on 18 of the 32 otolith ages (from the N165 survey) which were in disagreement was reached during the workshop (Table 3). Reasons for the disagreements were determined as follows:
a. A proximity of the last 2 hyaline zones may have been interpreted as a check within one annulus or alternately as 2 annuli (Fish Nos. 166,184,192,195,440,890).
b. The second hyaline zone was identified as a check by the Canadian ager but as the second annulus by the USA ager. The Canadian ager's interpretation allowed for a great deal of growth between the 1st and 2nd annulus. This difference in interpretation was discussed with several other age readers. The interpretation that a large amount of growth existed between the 1st and 2nd annulus was considered correct (Fish No. 183).
c. A strong hyaline zone was interpreted as a check by the Canadian ager but as the 1st annulus by the USA ager (Fish Nos. 173,183,213,215).
d. There was difficulty in interpreting poorly defined hyaline zones. This occurred if checks in the dorsal zone were abundant, or when spacing of zones was irregular (Fish Nos. 239, 262,851 ), or when the first annulus was poorly defined (Fish Nos. 862, 867).
e. Discrimination of zones in the terminal dorsal area of older otoliths was found to be difficult, causing one of the readers to count one more annulus than the other (Fish No. 882).
f. Use by the Canadian ager of the proximal reading axis for ageing when the dorsal area was hard to interpret due to a high number of checks. (Fish Nos. 875, 940)

The level of agreement between scales and otoliths as read by the USA ager was $75 \%$ for the N165 survey (Tables 3 and 7) and 76\% for the commercial fishery samples (Tables 4 and 8). When differences in the ages determined from scales and otoliths occurred, the scale age was almost always lower. A difference of up to 8 annuli occurred between scales and otoliths. As the otolith age increased, the difference between otolith and scale age generally increased. The smallest fish length for which the scale age was less than the otolith age was 55 cm . Unfortunately, only 16 otoliths were collected during the N165 survey from the western part of Georges Bank (Strata 5Z5,5Z6,5Z7) due to the small number of haddock caught. Of the 9 fish that were over 50 cm in length, 3 of the scale ages were lower than the otolith ages (Table 3).

## CONCLUSIONS

Agreement between the Canadian and USA ageing of haddock otoliths was satisfactory although there was a bias against age 6 by the Canadian reader that was not resolved. The Canadian reader's ages of 5 or 7 placed those fish in the strong 1985 or 1987 year classes as opposed to the very weak 1986 yearclass (for age 6).

The scale versus otolith results verify conclusions from the 1991 ageing workshop (Buzeta et al. 1992) that there is a bias towards under-ageing 5 Z haddock greater than 50 cm with scales. Although sampling from the western portion of Georges Bank was inadequate, there are indications that this bias is a problem in that region also. The USA lab has changed to a policy of collecting otoliths for haddock greater than 50 cm . during surveys but scales were still the predominate structure used to age the 1993 commercial fishery samples. The magnitude of the effect of ageing haddock with scales on the catch at age structure of the USA commercial fishery and surveys should be ascertained. It is recommended that the USA lab address this problem.

## III. GENERAL RECOMMENDATIONS

1. It was agreed that a maximum of one hundred otoliths per year be exchanged. The number exchanged should be increased if agreement becomes poor. Seasonality should be incorporated into the sample selection (ie., 50 otoliths from the Canadian spring survey and 50 from the USA fall survey).
2. Workshops are seen as necessary only every other year, unless agreement decreases in the interim.
3. The magnitude of the effect of ageing haddock with scales on the USA catch and survey age structure needs to be determined.

## ACKNOWLEDGEMENTS

The authors wish to thank G. Donaldson and D. Lyon for the collection of cod and haddock ageing material. J.J. Hunt and F. Almeida helped plan the workshop. M. Strong and E. Trippel reviewed the manuscript and provided many useful comments.
