AN UPDATE OF THE STATUS OF THE STOCK OF AMERICAN PLAICE IN SUBAREA 2 + DIV. 3K

by

W. Brodie, J. Morgan, and W. R. Bowering

Department of Fisheries and Oceans
P. O. Box 5667
St. John's, Newfoundland, Canada A1C 5X1

'This series documents the scientific basis for the evaluation of fisheries resources in Atlantic Canada. As such, it addresses the issues of the day in the time frames required and the documents it contains are not intended as definitive statements on the subjects addressed but rather as progress reports on ongoing investigations.

Research documents are produced in the official language in which they are provided to the secretariat.

¹La présente série documente les bases scientifiques des évaluations des ressources halieutiques sur la côte atlantique du Canada. Elle traite des problèmes courants selon les échéanciers dictés. Les documents qu'elle contient ne doivent pas être considérés comme des énoncés définitifs sur les sujets traités, mais plutôt comme des rapports d'étape sur les études en cours.

Les Documents de recherche sont publiés dans la langue officielle utilisée dans le manuscrit envoyé au secrétariat.

ABSTRACT

The stock of American plaice in NAFO Subarea 2 plus Division 3K is currently at the lowest level on record. Catches have declined to an average of less than 100 t per year during 1992-1994. Research vessel surveys indicate that the stock size is currently less than 5% of the values measured in the early 1980's. The relatively small catches from this stock cannot explain the large decline in abundance. The prospects for stock rebuilding in the short to medium term are extremely poor.

RÉSUMÉ

Le stock de plie canadienne de la sous-zone 2 et de la division 3K de l'OPANO est actuellement au plus bas niveau jamais enregistré. Les prises ont chuté pour atteindre une moyenne annuelle de moins de 100 t de 1992 à 1994. D'après les relevés de recherche, l'abondance du stock se situe actuellement à moins de 5 % des valeurs observées au début des années 1980. Les prises relativement basses dans ce stock n'expliquent pas la chute importante de l'abondance. Les possibilités de reconstitution du stock à court et moyen termes sont extrêmement faibles.

Description of the fishery

Catches increased steadily throughout the 1960's, peaking at 12,686 t in 1970 (Fig. 1). After the declaration of the 200 mile limit in 1977, catches by non-Canadian fleets were greatly reduced, with the result that the total catch from the stock exceeded 2,000 t on only 2 occasions after 1981. Catches from 1992 to 1994 averaged less than 100 t per year, and are by far the lowest in the time series. This is due to a drastic reduction in the TAC in 1994 (Fig. 1), as well as the moratorium on the northern cod fishery, which, beginning in July 1992, eliminated the by-catch of plaice in that fishery.

In most years prior to 1992, a large percentage of the catch came from Div. 3K, with recent exceptions of 1989 and 1990 when a directed fishery occurred in the autumn in Div. 2J. Catches from Div. 2GH combined have not exceeded 125 t in any year since 1972 (Table 1), and have been negligible in many years. In most years prior to 1991, the inshore catch from the stock ranged between 500 and 2,000 t. The offshore catch fluctuated widely, as it was often more economical for the offshore fleet to fish for plaice in the southern divisions of Subarea 3.

In its November 1994 report, the FRCC recommended that there be no directed catch from this stock in 1995 and that by-catches be limited to 100 t. This was similar to the advice in the previous year, which limited by-catches to a maximum of 500 t.

Available Data

1) Commercial fishery

Catch/effort

CPUE data are available from Canadian offshore otter trawlers for the period 1976-92. However, in only 2 of the last 11 years did the main species plaice catch exceed 500 t, and in many years it was negligible. Therefore these data cannot be used as an index of abundance for this stock and by-catch catch rates are not considered to be representative of stock abundance (Brodie et al., 1993).

Catch at age and mean weights at age

Catch at age data for this stock are available for the period 1984-90, based on samples from the Canadian fisheries. For many years prior to 1984, and for 1991 to 1994, sampling data are either non-existent or inadequate to calculate catch at age. In most years, ages 9-12 comprised the bulk of the commercial fishery, and there was a declining trend in the catch numbers of older individuals up to 1990 (Brodie et al., 1993).

2) Research vessel surveys

Abundance and biomass estimates

Stratified random surveys have been conducted in Div. 2G, 2H, 2J, and 3K since the late 1970's, although not annually in Div. 2GH. The trawlable biomass index in Div. 2G was relatively low in all surveys although coverage was poor in most years except 1987 and 1988. In both Div. 2G and 2H, the biomass estimates declined substantially from the late 1970's to the late 1980's (Tables 2 and 3).

In Div. 2J, where survey coverage has been virtually complete since 1981 (Table 4), the trawlable biomass index has declined drastically from estimates of about 90,000 t in 1982-83 to around 2,000 t in each year from 1992-1994 (Fig. 2). Div. 3K shows a similar pattern, with the biomass declining from a range of 25,000 to 40,000 tons between 1979 and 1987 to a level around 3,000 t in the 3 most recent surveys (Table 5, Fig. 2). The 1994 values are the lowest on record in both Div. 2J and 3K (Table 6). It should be noted that Div. 2J and 3K were restratified in 1993 to account for corrections to the depth contours on new navigational charts of these areas (Bishop, 1994). Therefore the stratum by stratum comparisons are split into 2 periods: prior to the 1993 survey, and from the 1993 survey onward (Tables 4-6), as there were changes to some stratum boundaries.

There has been a gradual reduction in the numbers of older fish caught in the surveys, consistent with the commercial fishery data. Virtually all cohorts declined at very high rates from 1990 to 1993 (Tables 7 and 8), and current estimates of spawning stock (RV survey ages 9+) are in the range of 1 to 3 percent of peak values. There has also been decreased recruitment in recent years (Fig. 3), although the decline is not as severe as the overall decline in stock abundance (Figs. 4 and 5). Mean weights at age from fish sampled during the surveys do not indicate any substantial trends (Fig. 6). Age specific data from the 1994 survey are not available at this time.

Distribution

Shifts in the depth distribution of the biomass to deeper water occurred during 1986-89 in both divisions, and were followed by rapid declines to very low levels (Fig. 7). In Div. 2J, plaice in the shallowest depth zone (101-200 m) accounted for 45 to 85 percent of the biomass in that division in the years 1977 to 1988. In 1989, this percentage dropped to less than 5, and has remained at a level less than 20 % in all subsequent surveys. This pattern is easily seen in Fig. 8, as the concentrations of plaice on Hamilton Bank and in the southwestern portion of Div. 2J, present in most surveys up to 1988, were not found in subsequent surveys. In 1989 and 1990, before the biomass declined to the current low level, plaice in Div. 2J were found to the east of Hamilton Bank, and in the Hawke Channel. Similar patterns were observed in Div. 3K, with plaice becoming less abundant in the shallower areas west of Funk Island Deep (Figs. 7 and 8).

Discussion

It is clear from the RV survey data that this stock has declined to an extremely low level in recent years. Catches in the commercial fishery, even before the moratorium on northern cod in 1992, had been decreasing, and the catch in 1991 of 500 t was then the lowest in about 30 years. Catches in the 3 years since then have not exceeded 105 t in any year, yet the biomass has remained at a very low level, and may still be declining.

With the stock size estimated from surveys in the early to mid 1980's, and the relatively low catches in the commercial fishery since then, it is evident that fishing mortality alone cannot explain the magnitude of the declines in stock size which have occurred. Using catch in year n divided by the RV biomass index in year n-1 (surveys are November-December) as a proxy for fishing mortality, reveals that during the period of greatest decline (1982/83 to 1987), this ratio did not exceed 5% in any year, and was below 2% in each year from 1981-84 (Fig. 9). In fact, the ratio never exceeded 9% and was less than 5% in 13 of the 16 years in the series. These values are substantially lower than the peak and mean values calculated for stocks of *A. plaice* in Div. 3LNO, and Subdiv. 3Ps. Myers (1994) examined the mortalities at age from the RV survey data, and concluded that there was high total mortality since the mid 1970's on the older ages, and that there may have been an increase in mortality during the last few years.

At present there is no explanation for the decline in this stock, or why it continues to decline with virtually no fishery in the past 3 years. It has been speculated that anomalously low water temperatures since the mid-1980's may have affected distribution and abundance, but no mechanism has been established. Predation by seals has been hypothesized as a reason for the decline, particularly by many in the fishing industry. Recent studies show that *A. plaice* do not constitute a major portion of seal diets in this area, although total consumption of plaice by seals is not yet available. It is unlikely that plaice migrated out of the area altogether, as no increase in abundance was observed in any other nearby plaice stocks (in fact, the adjacent stock in Div. 3LNO has declined at a similar rate). In any case, plaice are not generally known to make long range migrations. Dumping and/or misreporting are also unlikely, given that quotas on this stock throughout the 1980's were non-restrictive, and year-round markets existed for this valuable catch. Some discarding undoubtedly occurred, but at low levels relative to the total reported catches.

Prognosis

Given the current stock size estimates from surveys, there can be no optimism in the short or medium term. Even with negligible catches, the stock size has remained extremely low since 1991. The prospects for rebuilding in the longer term are unknown, although "a recovery of the fishery is unlikely before at least 10 years" (FRCC report, Nov. 1994). The 1995 TAC of 100 t is for by-catch only, with no provision for a directed fishery. Any fishery in 1996 could be detrimental to stock rebuilding.

Table 5. Mean weight (kg) of *A. plaice* per tow, per stratum from research vessel surveys in Div. 3K, 1977-92. No. sets in brackets.

Table 6 . Average weight (kg) per 30-minute set of A. plaice from the autumn survey of the GADUS ATLANTICA in Div. 2J and 3K during 1993-94.
Based on the new stratification system.

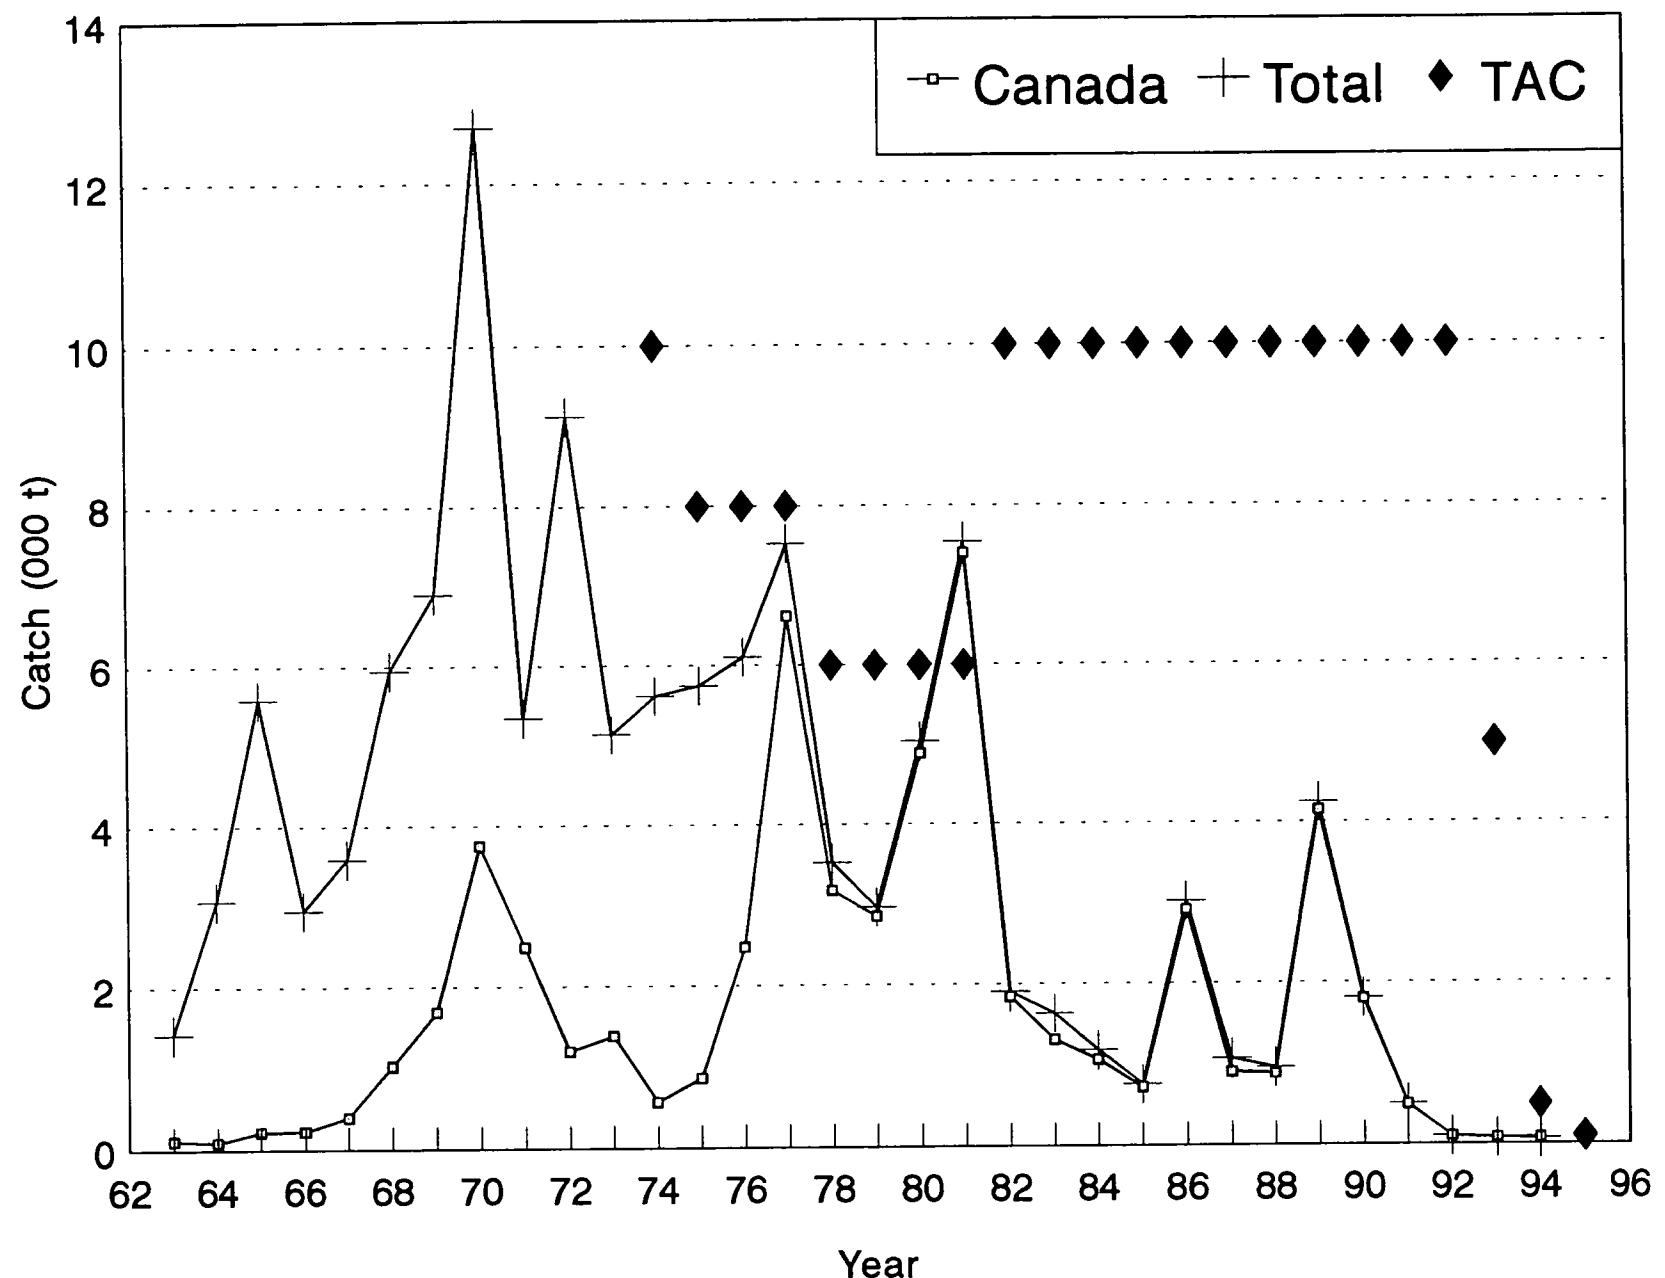

Fig.1. Catches and TAC's (000t) of *A. plaice* in NAFO SA 2 + Div. 3K.

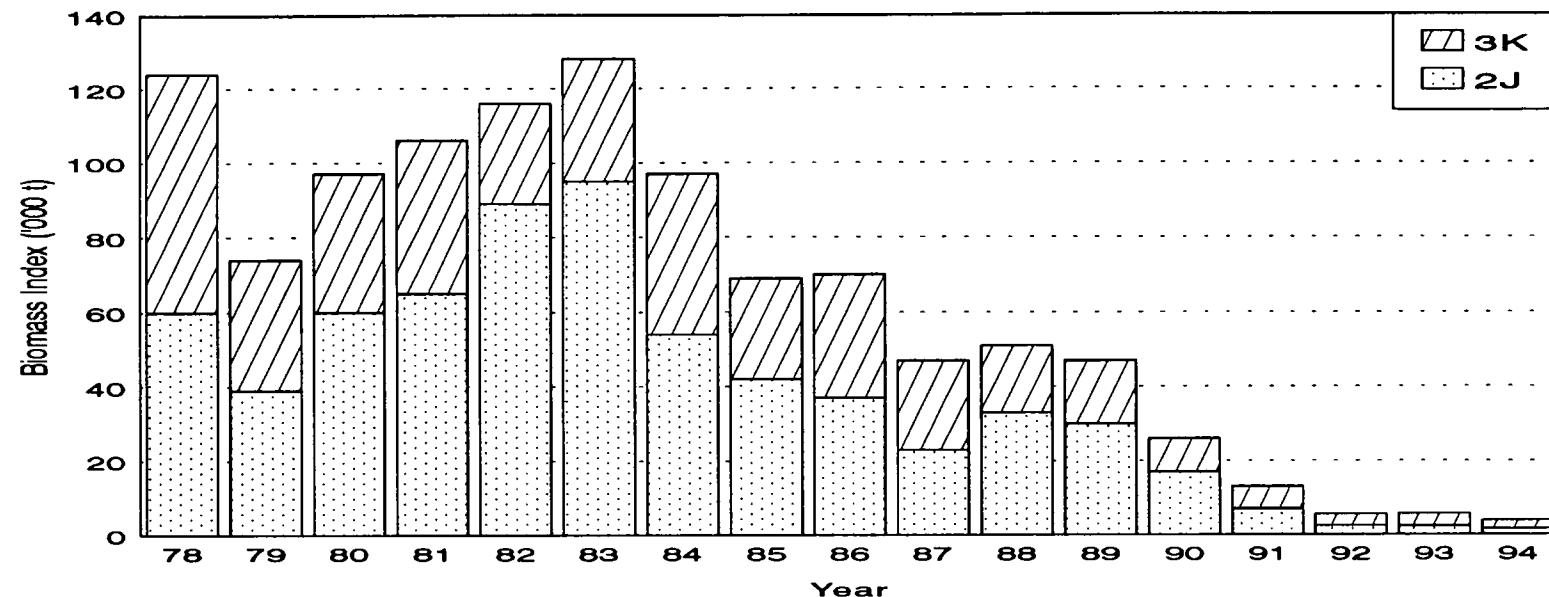

Fig. 2 . Estimated trawlable biomass of *A.plaice* from RV surveys in Div. 2J and 3K.

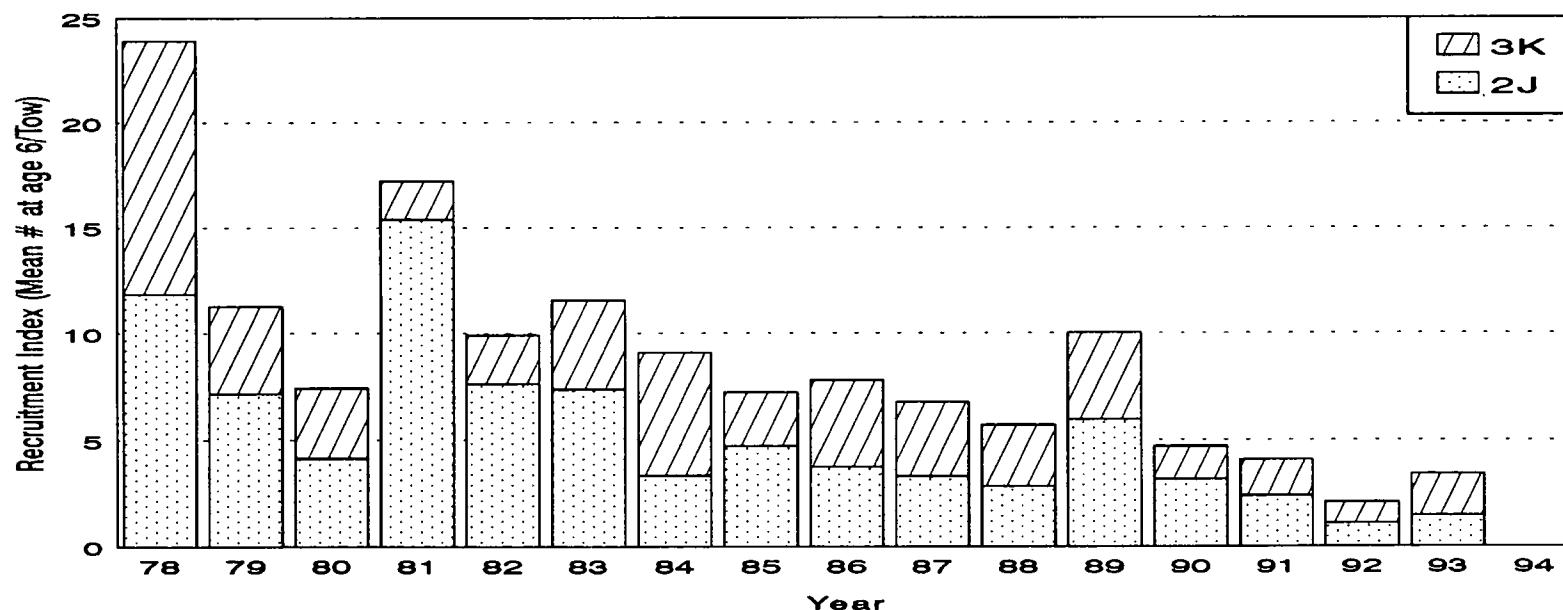

Fig. 3 . Estimated recruitment (age 6) of *A.plaice* from RV surveys in Div. 2J and 3K.

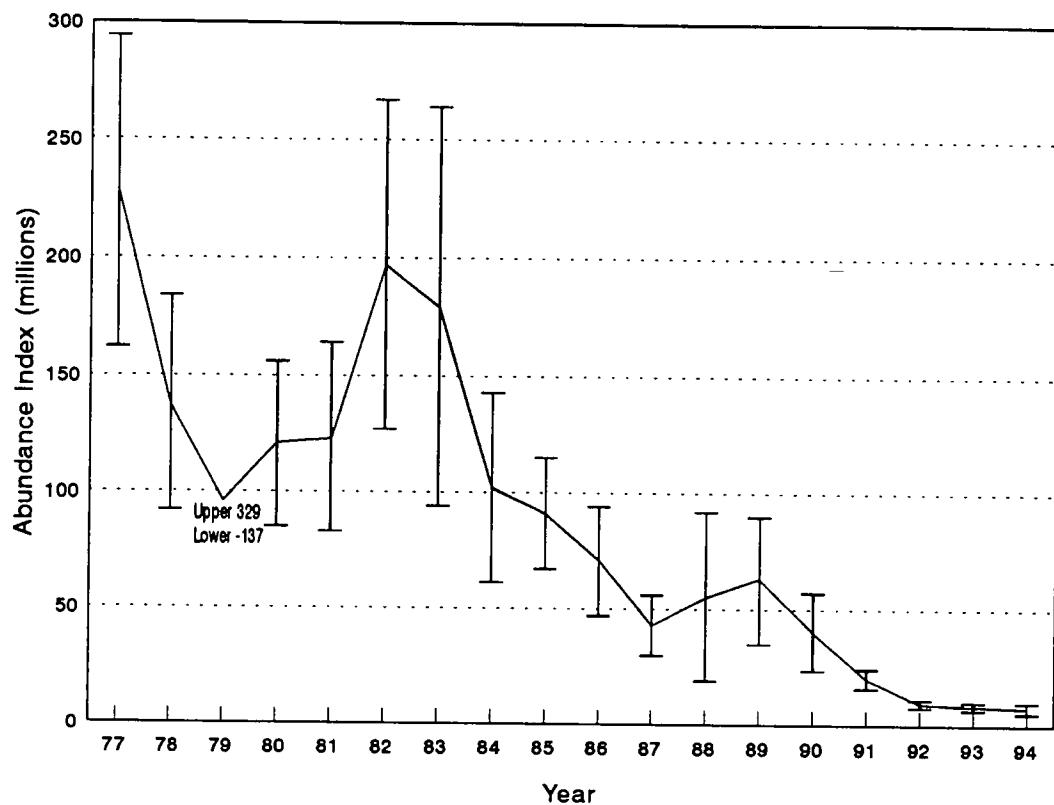

Fig. 4 . Abundance estimates of *A.plaice* (with 95% C.I.) from Canadian fall surveys in Div. 2J.

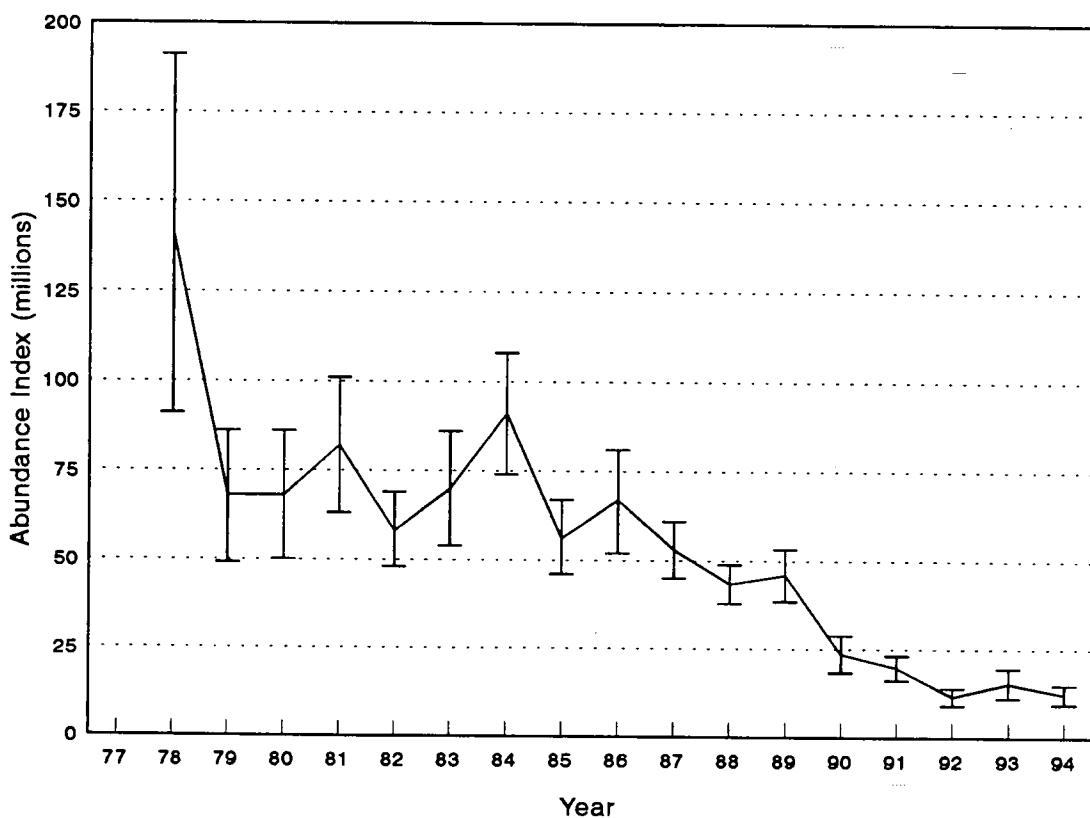

Fig. 5 . Abundance estimates of *A.plaice* (with 95% C.I.) from Canadian fall surveys in Div. 3K.

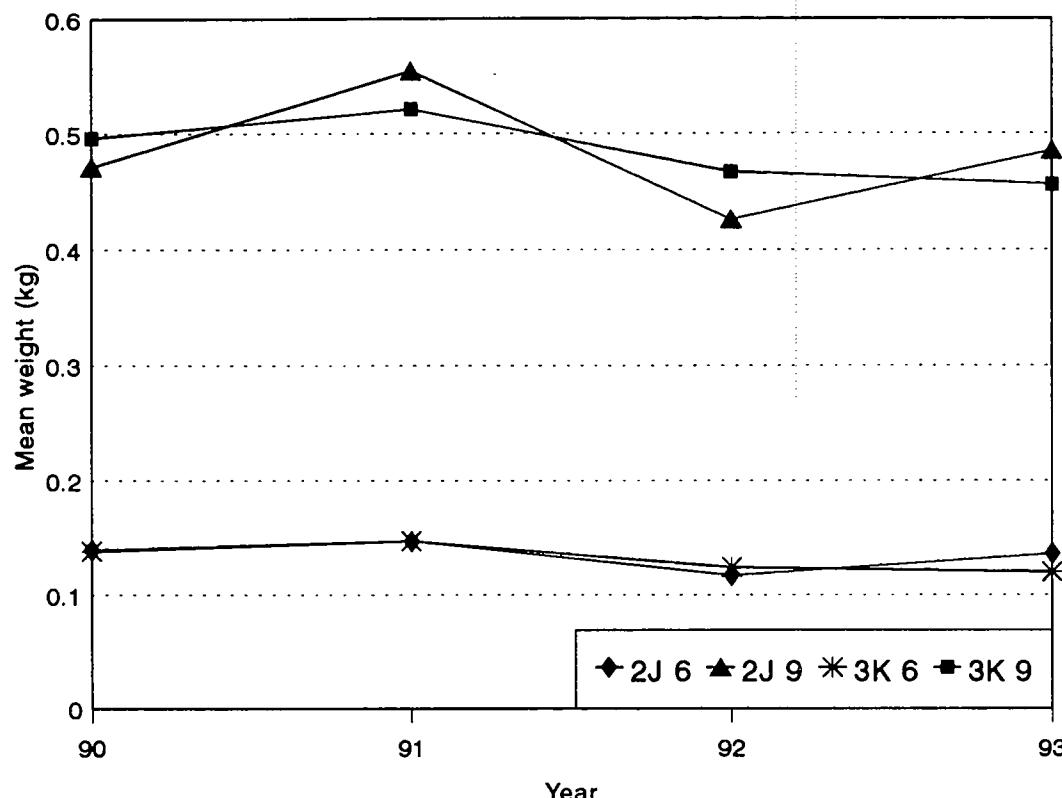

Fig. 6 . Mean weights at ages 6 and 9 of *A. plaice* from RV surveys in Div. 2J and 3K, 1990-93.

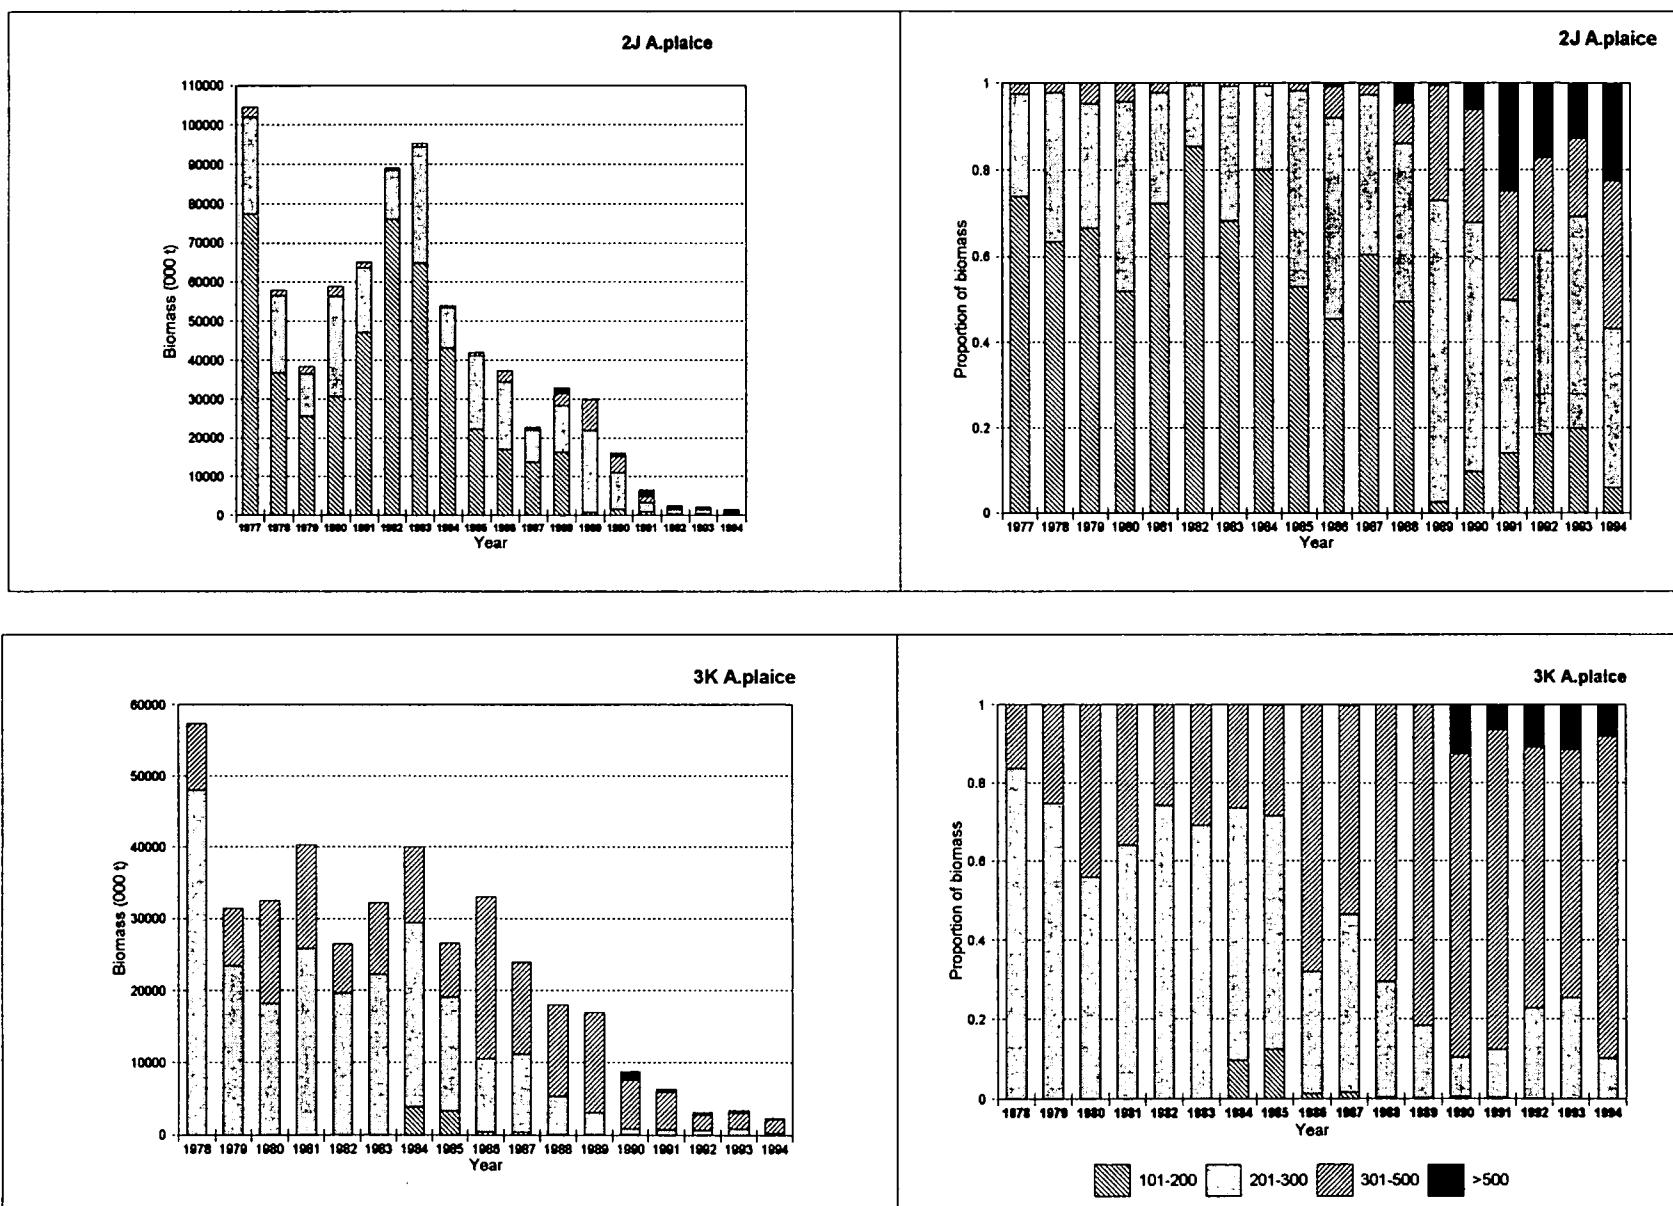

Fig. 7. Estimates of biomass, and proportion of biomass, by depth zone, for A. plaece in Divs. 2J and 3K from RV surveys from 1977 to 1994.

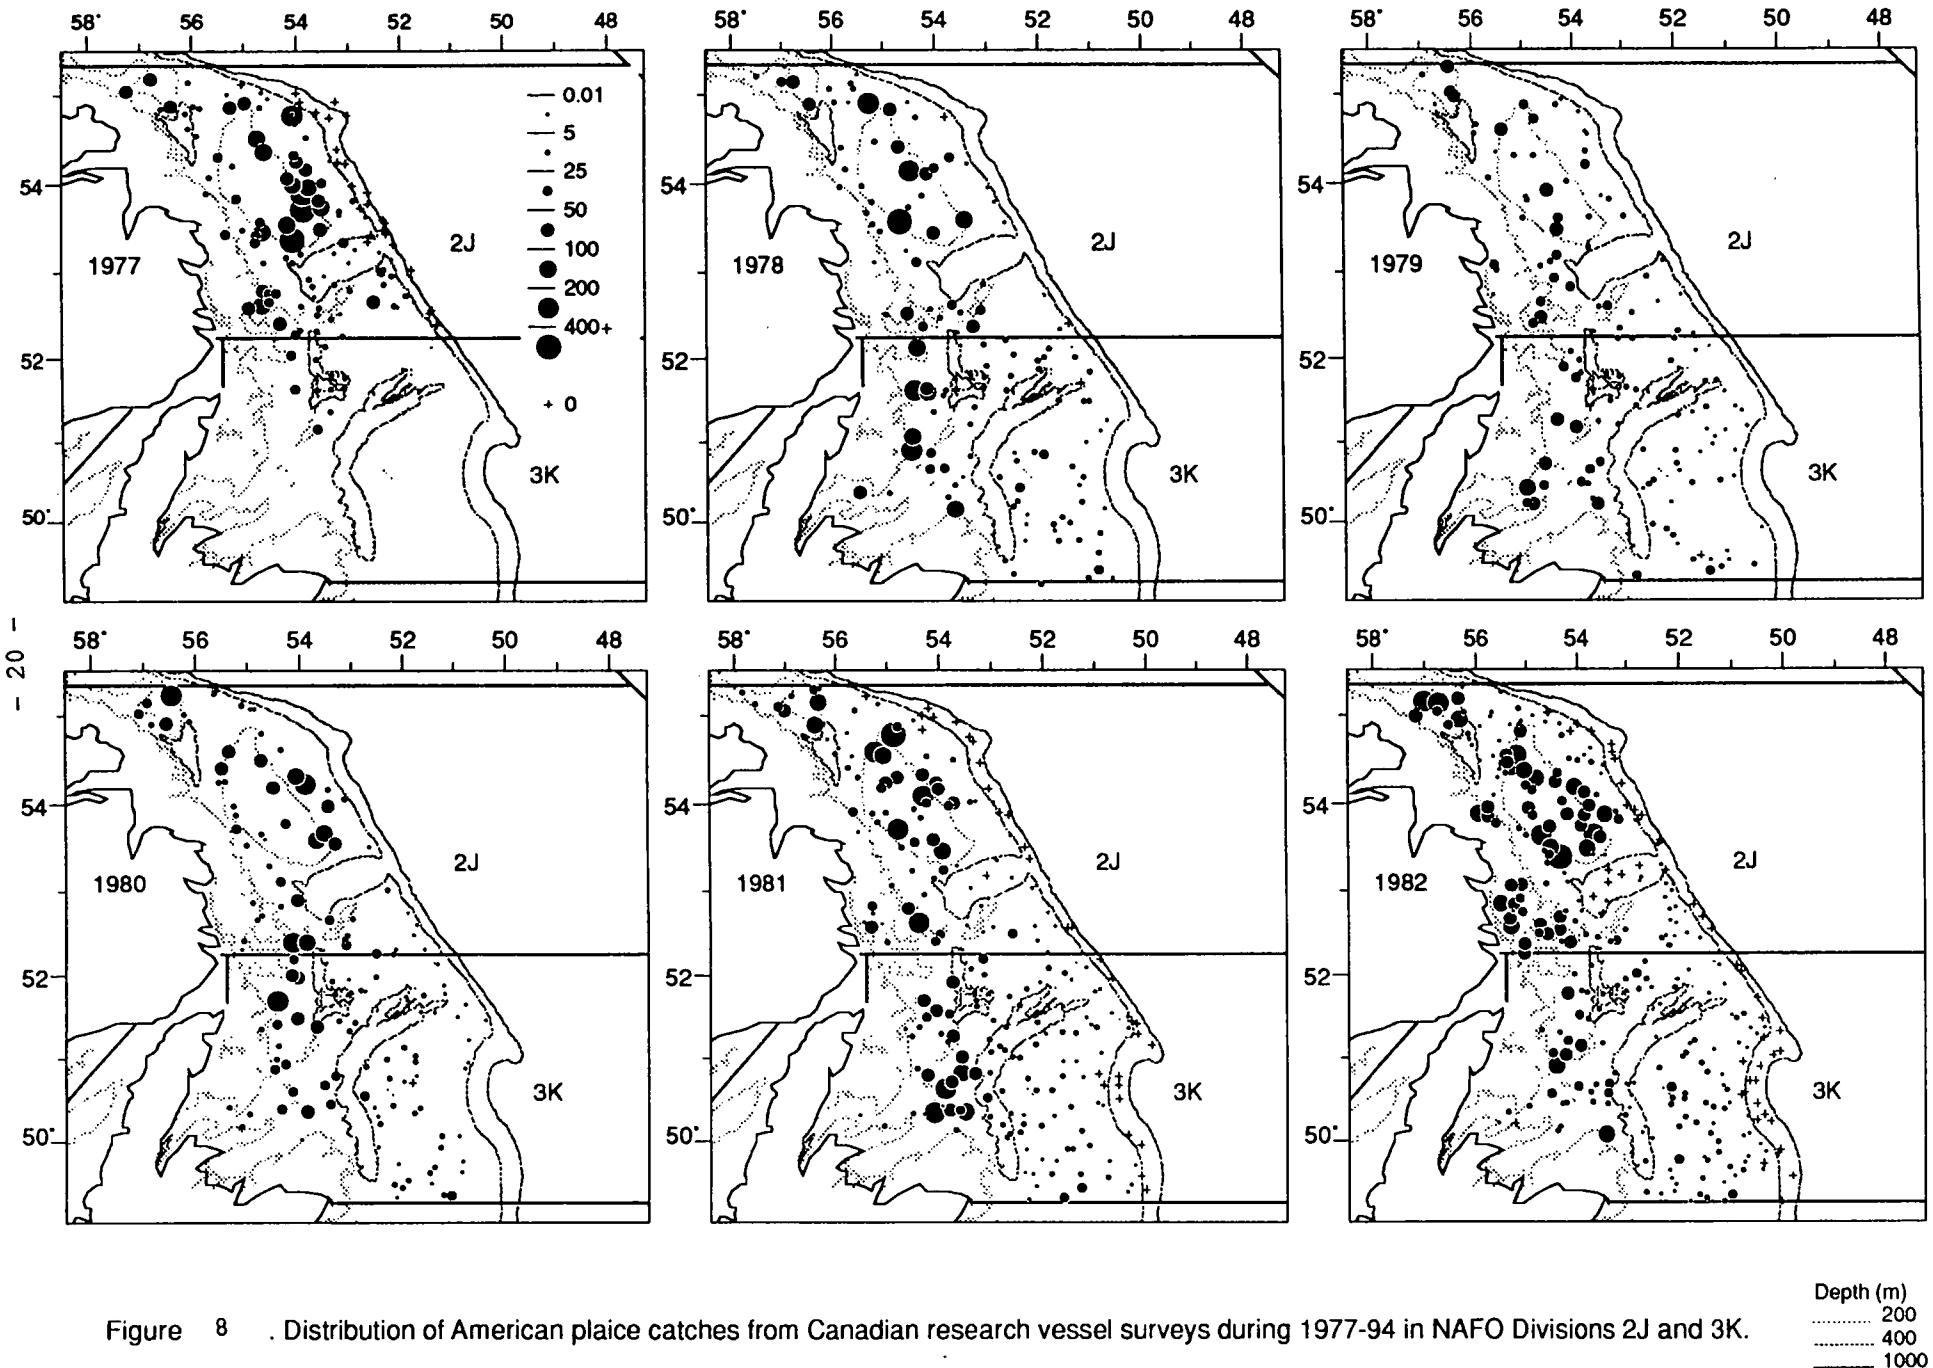

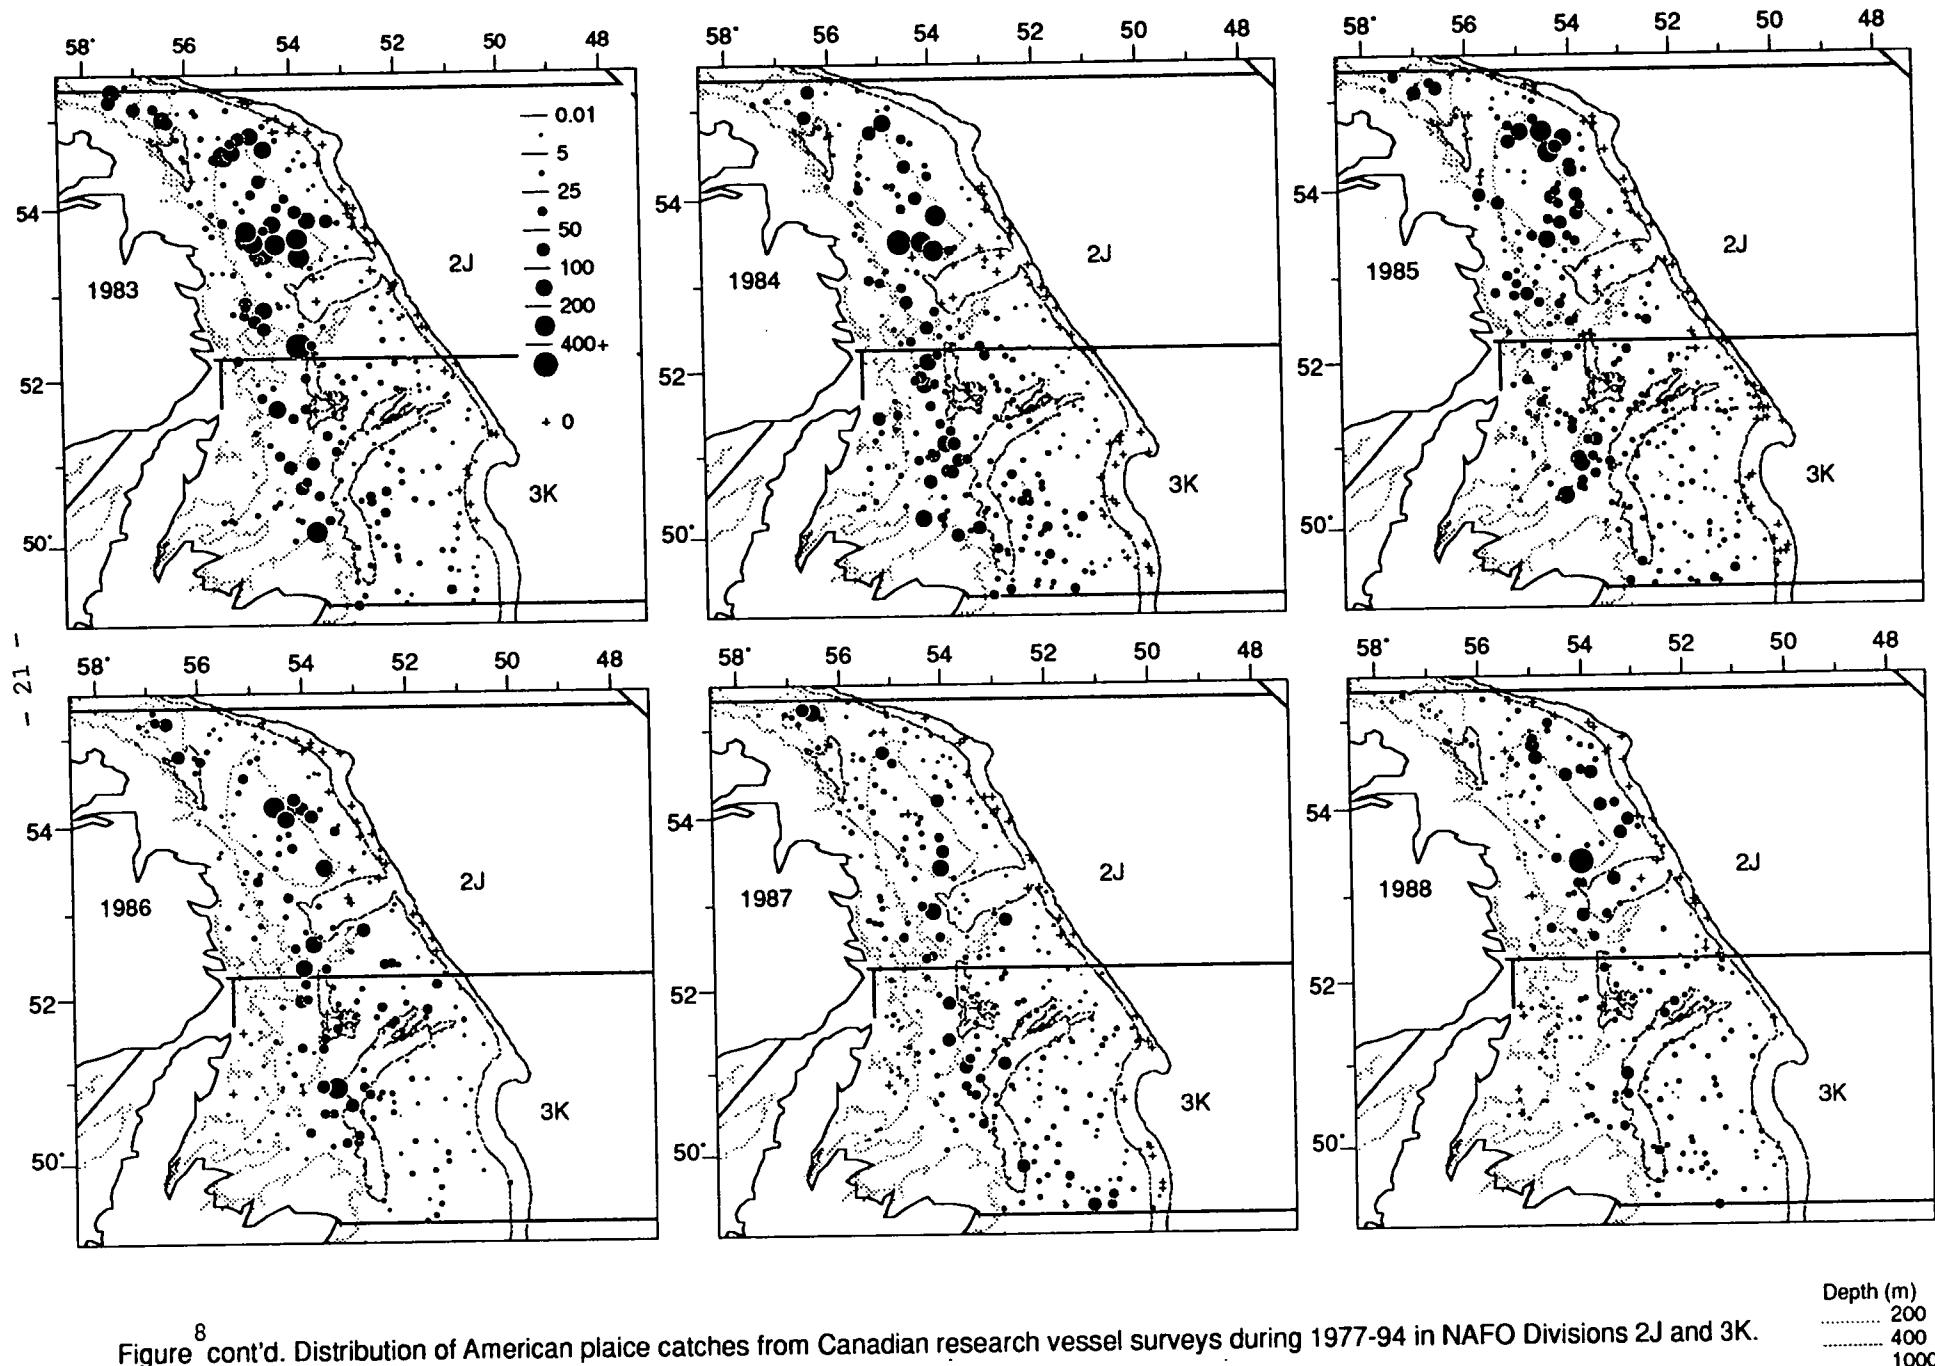

Figure 8. Distribution of American plaice catches from Canadian research vessel surveys during 1977-94 in NAFO Divisions 2J and 3K.

Depth (m)

- 200
- 400
- 1000

⁸ Figure cont'd. Distribution of American plaice catches from Canadian research vessel surveys during 1977-94 in NAFO Divisions 2J and 3K.

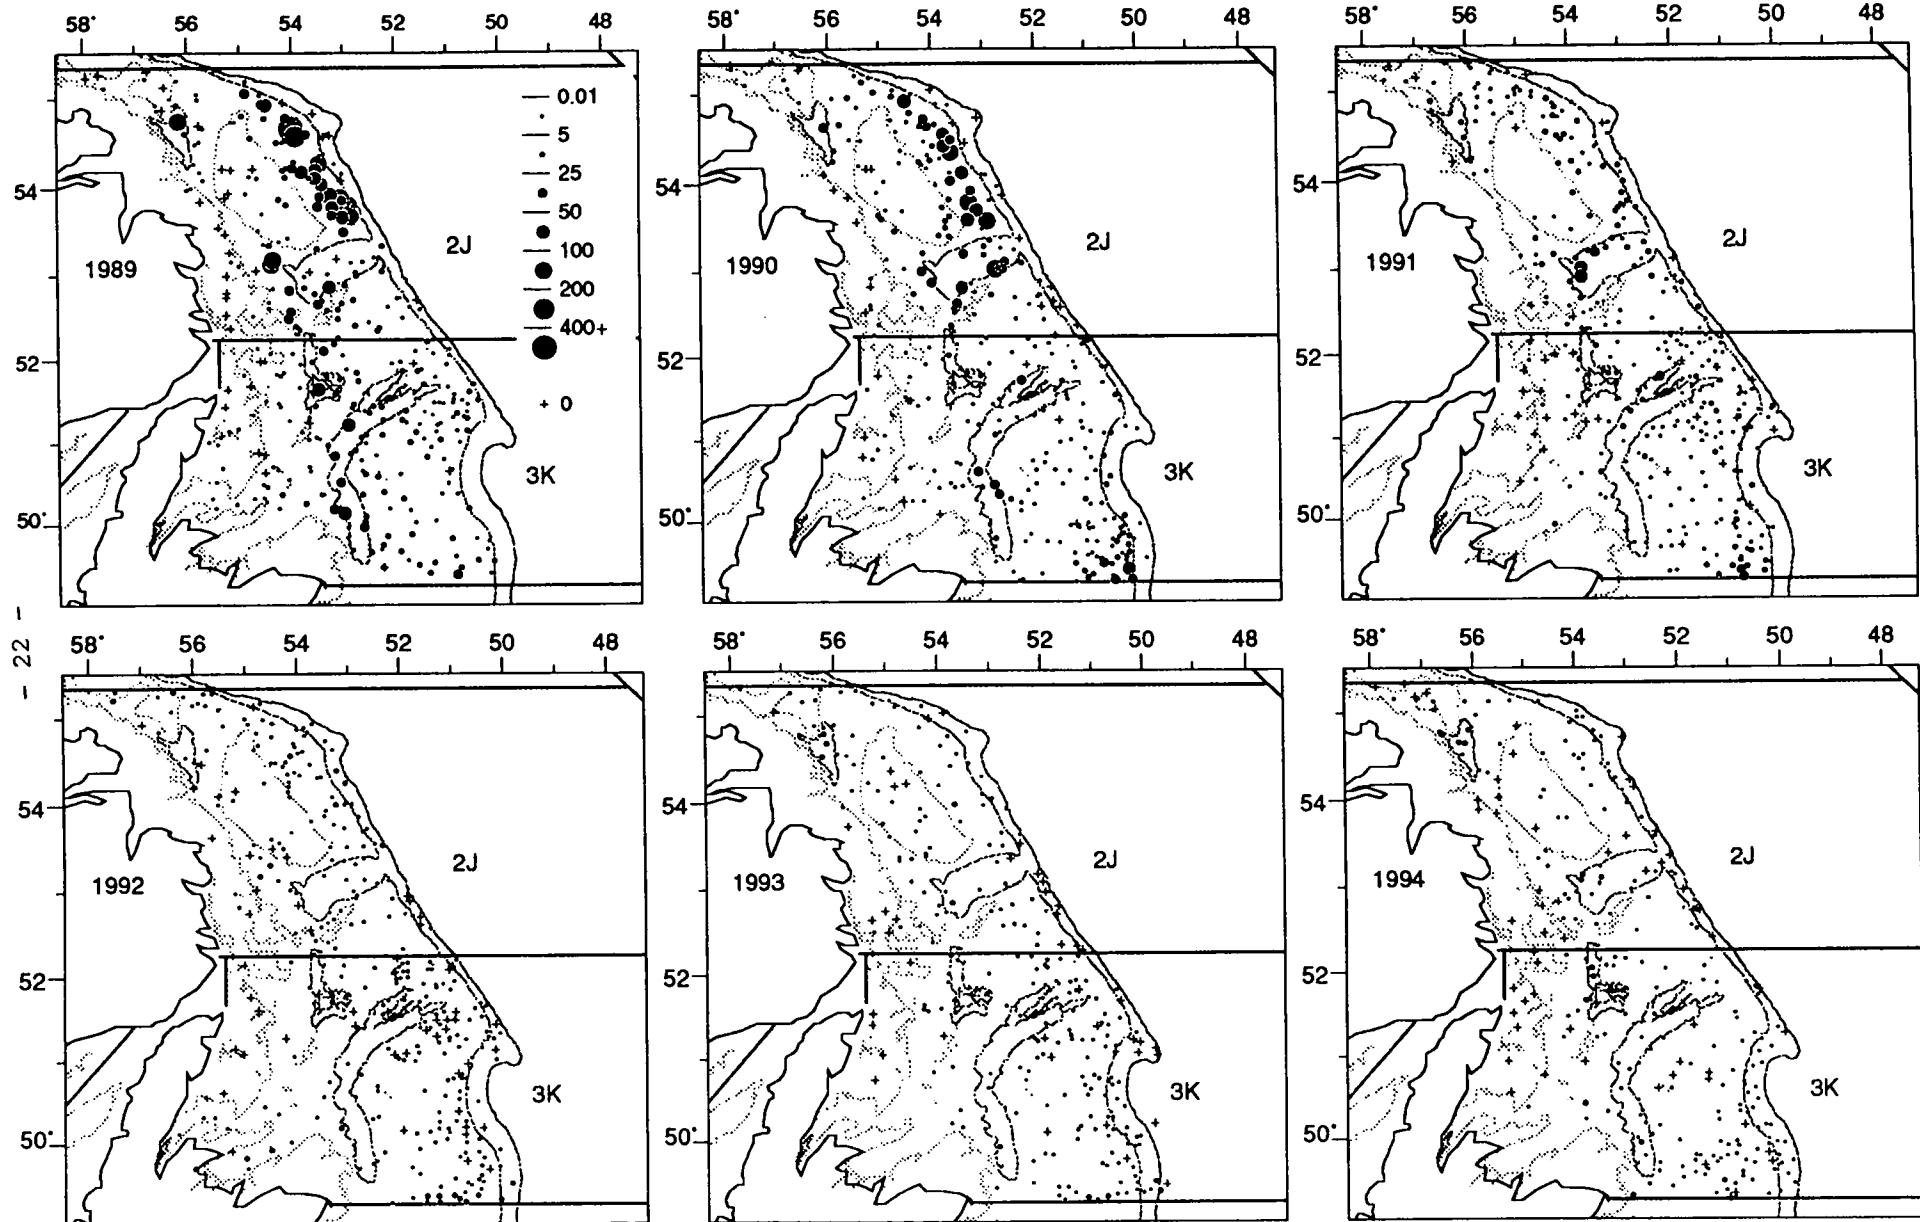

Figure 8⁸ cont'd. Distribution of American plaice catches from Canadian research vessel surveys during 1977-94 in NAFO Divisions 2J and 3K.

Depth (m)

- 200
- 400
- 1000

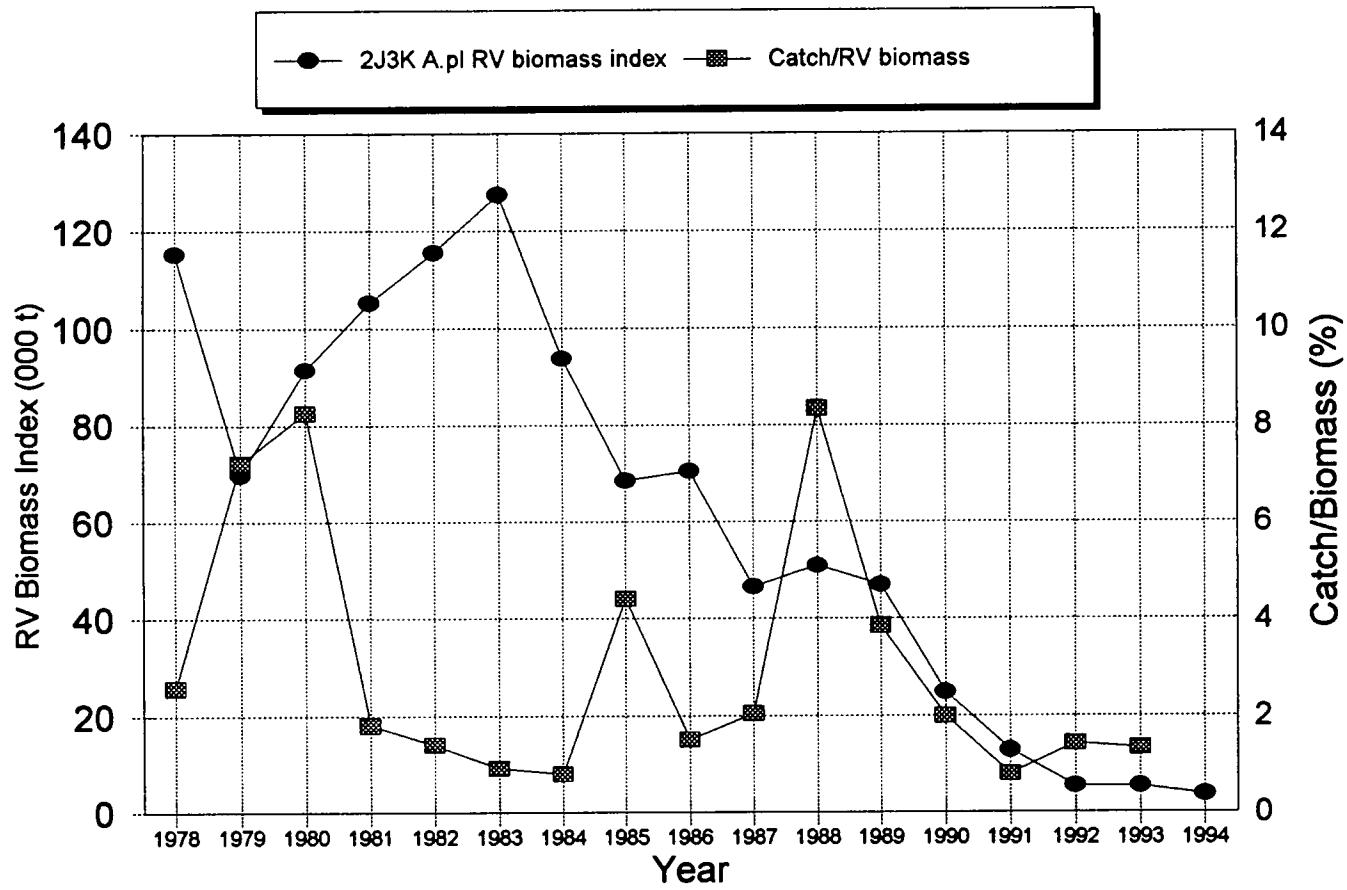

Fig.9. Comparison of RV biomass and Comm. catch as % of RV biomass.
