<sup>1</sup>This series documents the scientific basis for the evaluation of fisheries resources in Atlantic Canada. As such, it addresses the issues of the day in the time frames required and the documents it contains are not intended as definitive statements on the subjects addressed but rather as progress reports on ongoing investigations.

Research documents are produced in the official language in which they are provided to the secretariat.

<sup>1</sup>La présente série documente les bases scientifiques des évaluations des ressources halieutiques sur la côte atlantique du Canada. Elle traite des problèmes courants selon les échéanciers dictés. Les documents qu'elle contient ne doivent pas être considérés comme des énoncés définitifs sur les sujets traités, mais plutôt comme des rapports d'étape sur les études en cours.

Les Documents de recherche sont publiés dans la langue officielle utilisée dans le manuscrit envoyé au secrétariat.

## ABSTRACT

Recent research vessel surveys have shown the stock size of American plaice in NAFO subdivision 3Ps to be at its lowest observed level. The stock size is currently only 10% of the average levels observed in the mid 1980's. Although catches may have added to the decline of this stock in recent years, the large decline observed in the late 1980's occurred when catches were low. This stock is well below historic levels, with no immediate prospects of rebuilding.

## Résumé

Il ressort des relevés de recherche récents que le stock de plie canadienne dans la subdivision 3Ps de l'OPANO est au plus bas niveau observé à ce jour, soit à seulement 10 % environ des niveaux moyens enregistrés vers le milieu des années 1980. Quoique les prises aient pu contribuer au recul du stock ces dernières années, le fort déclin observé à la fin des années 1980 s'est produit alors que les prises étaient faibles. Ce stock se trouve bien en deçà de ses niveaux antérieurs et n'offre pas de perspectives de rétablissement dans l'immédiat.

### Description of the fishery

Catches from this stock were highest from 1968 to 1973, exceeding 12,000 t on three occasions in this period (Fig.1, Table 1). Catches by foreign vessels peaked at about 8800 t in 1968, due mainly to the USSR catch, and have not exceeded 800 t since 1973. Catches by France ranged from 540 t to 760 t from 1986-89, but declined to only 26 t in 1992. There has been no French catch reported since 1992. In 1993, both offshore and inshore catch were the lowest in the time series up to that time (Table 2). This fishery has had a substantial main species plaice component and has often been prosecuted in the first quarter (Table 3). Overall, the catch in 1993 was 751 t, the lowest since the early 1960's. Based on a recommendation by the FRCC the fishery was closed in September of 1993 for the remainder of that year. The TAC for 1994 was set at 500 t to allow a by-catch in other fisheries. Total catch in 1994 was 117 t. 56% of the catch was taken by otter trawl (Table 4). There is a 100 t by-catch quota for 1995.

### Available Data

#### Catch at age and mean weights at age

The catch at age and mean weights at age for this stock have been based on sampling from the Canadian fishery, as no sampling data were available for the French catches. In 1993 the catch was comprised mainly of fish aged 8-12, similar to most years (Brodie et al. 1993), although there was no sampling data from the inshore catch in 1993, which comprised 60% of the catch weight. The mean weights at age in 1993 and 1992 were lower than recent values, due in part to the absence of the inshore sampling. Inshore gear tends to catch larger fish at age so that absence of sampling from this fishery would tend to result in a bias in the mean weights at age.

#### Catch effort data

A multiplicative analysis of commercial catch rates of American plaice for the Canadian offshore trawler fleet in Subdiv. 3Ps has not been updated since 1993 because of very low catch (main species plaice catch = 48 t) and closure of the fishery in 1993. The analyses of CPUE done in 1993 (Brodie et al. 1993) showed relative stability from 1987 to 1990, at about the same level observed in 1981-83, then a sharp decline to the lowest observed levels in 1991 and 1992. Reports from the fishing industry indicated very poor catch rates in this fishery in 1993.

#### Research vessel survey biomass and abundance

Stratified-random surveys have been conducted by Canada in Subdiv. 3Ps in each year from 1972 to 1995. There were two surveys in 1993, one in February and one in April. Most of the surveys prior to 1993 were in February, while those since 1993 have been in

April. Tables 5, 6 and 7 show the results from these surveys, and it can be seen that survey coverage was poor in many years prior to 1979. The biomass index (Fig.2) was relatively stable from 1986 to 1988, around 30,000 t, the value from the 1989 survey was substantially lower at 17,000 t, and 6 of the 7 surveys since then have produced estimates less than 7,000 t. It should be noted that there has been a monotonic decline in the biomass index since 1987, with the exception of the 1990-91 points. However, the 1990 survey missed several key strata in Subdiv. 3Ps, including 4 of the 6 strata with the highest densities of *A. plaice* in the 1991 survey (Table 5). Thus the 1990 survey results are probably underestimated. The 1994 survey gave an estimated biomass index of 4,156 t and the estimate from the 1995 survey is 3,944 t. Tables 6 and 7 reflect the changes made to the stratification scheme in subdivision 3Ps in 1994 and 1995. Most of the biomass in recent surveys was in deeper areas than usual with relatively higher biomass at greater than 150 fathoms since the late 1980's (Table 8).

Age-by-age estimates of abundance from the R. V. surveys are shown in Table 9. The catch numbers at length for the 1977-82 surveys carried out by the A. T. Cameron were adjusted by the appropriate conversion factors to make them comparable with the data from the 1983 to 1993 surveys. The data for 1977-90 were taken from a previous assessment of this stock, which used a multiplicative model to account for strata not surveyed in each year.

Table 9 shows the decline in abundance in this stock in recent years, with the two 1993 surveys being the lowest points in the 18-point series. The abundance of all age groups has declined and there has been a decrease in recruitment. Age-by-age data from the 1994 and 1995 surveys are not yet available. Abundance at length from these surveys does not indicate any increase in young fish (Fig.3).

Data from the French RV surveys in 3Ps also show a decline in abundance through 1992 (Brodie et al. 1993). There have been no French surveys since then.

#### **Age at Maturity**

Maturity at age was estimated from RV data for males and females in 3Ps from 1973 to 1993 using the method of Morgan & Hoenig (1993). From these estimates age at 50% maturity was calculated for each sex and year using probit analyses assuming a normal distribution. For both males and females there has been a dramatic decline in age at 50% maturity over the time period examined (Fig.4). For males, the average  $A_{50}$  from 1973 to 1982 was 6.67 y while in the 1984 to 1993 period it was 5.33 y with estimates for the last 3 years being less than 5 y. For females,

the average  $A_{50}$  from 1973 to 1982 was 10.61 y while in the 1984 to 1993 period it was 8.93 y with estimates in 6 of the last 10 years being less than 9 y. No ageing data is available since 1993.

### **Index of Female Spawning Stock Biomass**

An index of female spawning stock biomass was constructed from the r.v. survey data. Mean length at age for females was calculated for each age in each year from 1973 to 1993. A length weight relationship for females was calculated for each year from 1990 to 1993 and applied to the mean lengths at age to calculate mean weight at age. An average length weight relationship was also calculated for the 1990 to 1993 period and applied to all years prior to 1990, a period for which there is no individual weight data. Female spawning stock biomass was then calculated for each year using the mean weight at age, abundance at age and estimated proportion mature at age. Some caution should be taken in interpreting results prior to 1977 because of poor survey coverage in many of these years (Table 5). Female spawning stock biomass reached a peak at 37,000 t in 1985 (Fig.5) and has been declining since. The 1993 estimate of 1,900 t is the lowest since 1975. The female spawning stock biomass averaged 28% of the total biomass from 1973 to 1982. In the last 10 years it has averaged 51% of the total biomass. This is a result of increased proportion mature at age and low numbers of young fish.

### **Sequential Population Analyses (SPA)**

SPA results have not been presented for this stock since 1991, when various formulations of the Adaptive framework were attempted (Brodie 1991). The results of these SPA's were not acceptable, due to strong year effects in the residuals, an unexplained u-shaped pattern in the slopes of the calibration coefficients ( $q$ 's) by age, and a substantial discrepancy in the results using RV survey data compared to the results using commercial CPUE at age data. In addition, the RV survey estimates of abundance were quite variable in the 1989-1992 period, and the VPA calibrations were sensitive to these fluctuations. Given these problems, along with difficulties in calculating catch at age for 1993-94, SPA has not been used as the basis for the assessment of this stock in recent years.

We explored a more intuitive alternative to tuned VPA. Basically a VPA works by reconstructing the history of finished cohorts from catch data, and then using them to calibrate abundance indices for active cohorts. The catch history of the active cohort is then used to infer, say, its recruitment. Each finished cohort, and each age at which the calibration can be done, yields a separate estimate of the active cohort's recruitment. The variation in the separate estimates can then be displayed, as can any systematic dependence on things like the age of calibration or the

finished cohort from which it was calibrated.

Figure 6 shows the quartiles of all estimates of recruitment (age 6) of the active cohorts at the beginning of 1995 (taking age 19 as the oldest age of non-zero numbers). This was based on research vessel surveys from 1977 to 1993. Also shown is the recruitment estimated by the tuned VPA in the 1991 assessment document, which used surveys from 1977 to 1990. There is a clear discrepancy; the tuned VPA shows a much earlier decline in recruitment (Fig.6). The reason seems to be that the most recent (1990) survey in the VPA tuning was anomalously low (Table 9), as was noted in the earlier discussion of RV survey results. Although the plot of quartiles is presented as if every estimate had equal weight, in fact estimates based on calibrating at older ages (thus from more recent surveys for the active cohorts) should have less variance and therefore greater weight. The reason for this is that for the estimates calibrated at older ages, more of the recruitment estimate comes from the reconstructed catches, which are assumed in all of these analyses to be without error; and only a small part comes from the calibration of error-prone survey indices. Moreover, in the usual ADAPT tuning, low surveys are assumed to be more accurate. Taking account of surveys since 1990 gives a less extreme picture.

### Discussion

Similar to other stocks of *A. plaice* in the Nfld. & Labrador area, 3Ps plaice has declined markedly since the mid to late 1980's and is now at a level well below that of the early to mid 1980's. This is confirmed by all 3 indices (Canadian RV surveys up to 1995, French RV surveys up to 1992, and Canadian OT CPUE (1974-1992)), and by declines in the fishery. Recent surveys have shown no indication of recovery. Abundance at all ages has declined and it appears that recruitment has been low since the mid to late 1980's. There has been an increase in the proportion mature at age since that time, but this has not halted the decline in female spawning stock biomass.

As a proxy for the exploitation rate on the stock, the ratio of catch to trawlable biomass from surveys for the period 1983-93 was examined (Fig. 7). Both total catch and offshore catch only were used to calculate the ratios, as it was thought that the offshore catch was more comparable to the survey biomass index, in that both exclude plaice in the inshore areas. From 1983 to 1989, the annual ratio of catch to trawlable biomass was less than 10%, although the stock size declined substantially during this time. In the early 1990's, with the stock at a very low level, the catch to biomass ratio increased to levels much higher than those seen in the 1980's, then declined in 1993-94 with the large reductions in the fishery (Fig. 7). Thus it appears that during 1980's, when the major decline in stock size occurred, commercial catches were

unlikely to have been the major cause. However, in the early 1990's the catch to biomass ratio increased, and this may have accelerated the further decline in stock size.

The increasing trend in standardized fishing effort (Fig. 8) also suggests that exploitation increased in the early 1990's. This effort index in 1991-92 was about 3-4 times higher than it was in the early 1980's, whereas the stock size in the early 1990's was substantially lower than in the earlier period. Recent assessments have also indicated that fishing mortality probably increased in the late 1980's and early 1990's, although it was not possible to quantify the magnitude of the increase (Brodie et al. 1993).

#### *Outlook*

The outlook is very pessimistic, given the current low stock size, and the lack of recruitment indicated by the surveys. In the short to medium term, there is no prospect for stock rebuilding.

Table 5. Mean weight (kg) of American plaice per tow, by stratum, from r.v. surveys in Subdivision 3Ps. Numbers in parentheses are the number of successful 30-minute tows in each stratum. The stratified mean weight per tow and the biomass estimates are given at the bottom of the table. (ATC, AN, WT, refers to the research vessels, A.T. CAMERON, A. NEEDLER, and W. TEMPLEMAN respectively.)

Mean (No. sets)			2.8 (172)
Biomass (t) from surveyed strata			4,156

Table 7. Mean weight (kg) of American plaice per tow, by stratum, from r.v. surveys in Subdivision 3Ps in 1995. Numbers in parentheses are the number of successful 30-minute tows in each stratum. The stratified mean weight per tow and the biomass estimate are given at the bottom of the table. WT refers to the research vessel W. TEMPLEMAN).
