¹This series documents the scientific basis for the evaluation of fisheries resources in Atlantic Canada. As such, it addresses the issues of the day in the time frames required and the documents it contains are not intended as definitive statements on the subjects addressed but rather as progress reports on ongoing investigations.

Research documents are produced in the official language in which they are provided to the secretariat.

'La présente série documente les bases scientifiques des évaluations des ressources halieutiques sur la côte atlantique du Canada. Elle traite des problèmes courants selon les échéanciers dictés. Les documents qu'elle contient ne doivent pas être considérés comme des énoncés définitifs sur les sujets traités, mais plutôt comme des rapports d'étape sur les études en cours.

Les Documents de recherche sont publiés dans la langue officielle utilisée dans le manuscrit envoyé au secrétariat.

Abstract

A precautionary TAC of 1,500 t was in place for the 1994 halibut fishery. The domestic landings were below the TAC at 1,023 t. Allocations in 1994, under the 1,500 t TAC, were restrictive only to the 4VWX <65' fixed gear fleet and the <65' mobile gear fleet bycatch fishery on the Scotian Shelf. The EU continues to report very variable halibut catches outside the 200 mile limit that are not accounted for under the current management plan. Small longliners account for over 70 % of the landings. Commercial catch rates for this fleet have declined gradually in the 4VWX area, while showing stability since 1990 for 3NOPs. Total effort showed a declining trend from 1985 to 1992 and has remained more or less stable since. It appears that a large scale redirection of effort to halibut as a result of closures in other fisheries is not evident, and as halibut are a long lived species prospects for the 1995 and 1996 fishery are not likely to be greatly different from 1994. Research surveys indicated an increase between 1983 and 1991 and have declined since. The surveys generally catch smaller halibut than the commercial fishery, and may prove to be an indicator of recruitment rather than fishable biomass. The FRCC recommended a TAC of 850 t for the 1995 fishery. It will be necessary to maintain the present restrictions on the fishery for several years before it can be determined whether they are having the desired positive effect on stock status.

Résumé

Un TAC prudent de 1 500 t a été imposé à la pêche du flétan de 1994. Les débarquements canadiens, de 1 023 t, ont été inférieurs au TAC. Les allocations de 1994, accordées en vertu du TAC de 1 500 t, n'ont été limitatives que pour la flottille des moins de 65 pieds à engins fixes de 4VWX et pour la pêche accessoire de la flottille des moins de 65 pieds à engins mobiles du plateau néo-écossais. L'UE continue de signaler des prises de flétan très variables à l'extérieur de la zone de 200 milles; cette pêche n'est pas visée par le plan de gestion actuel. Plus de 70 % des débarquements sont faits par de petits palangriers. Les taux de prises commerciales de cette flottille ont diminué graduellement en 4VWX, mais sont demeurés stables en 3NOPs depuis 1990. L'effort total présente une tendance à la baisse de 1985 à 1992, mais est plus ou moins stable depuis lors. Il ne semble pas y avoir eu une importante réorientation de l'effort vers la pêche du flétan depuis la fermeture des autres pêches et comme le flétan est une espèce qui atteint un âge important, les pêches de 1995 et 1996 ne devraient pas différer beaucoup de celle de 1994. Les relevés de recherche ont indiqué une augmentation de l'abondance de 1983 à 1991 qui a été suivie d'un déclin. Les relevés donnent généralement lieu à la capture de plus petits flétans que la pêche commerciale et pourraient donc être un meilleur indice du recrutement que de la biomasse exploitable. Le CCRH a recommandé un TAC de 850 t pour la pêche de 1995. Les limitations actuelles devront être maintenues pendant encore plusieurs années avant qu'il ne soit possible de déterminer s'ils ont eu les effets souhaités sur le stock.

Introduction

Atlantic halibut (4VWX3NOPs) is the most highly valued groundfish species occurring in the Northwest Atlantic. Prior to 1988 the Atlantic halibut fishery was unregulated. This was mainly due to a shortage of stock assessment data, and a lack of interest in halibut management prior to that time. A halibut working group was formed at that time to look at management alternatives for the 1988 fishery. With increased interest in the fishery, and concerns expressed by industry, a precautionary TAC of 3,200 t was set in 1988 based largely on recent catch levels. A declining longline catch rate was noted as well. The TAC remained at this level until 1994 at which time, after reviewing the 1993 assessment information, the FRCC recommended that, as a precautionary measure, the 1994 TAC should be set at 1,500 t, rather than the previous 3,200 t. Due to concerns that the stock was still declining and that redirection of effort would result in higher mortality on halibut, the 1995 TAC was reduced to 850 t.

The Industry working group also recommended, and industry then requested, a minimum size limit of 81 cm for Atlantic halibut (Anon. 1987). This size limit was generally not enforced prior to 1990. Difficulties were encountered in determining the actual size of the landed fish, as many were landed without head, and/or tail. Mandatory landing of all groundfish was introduced for the 1993 fishery, thus eliminating the minimum size regulation for halibut. Fixed gear interests then requested that halibut be exempted from the mandatory landing regulation. Regulation 93.3 was subsequently amended to permit the discarding of dogfish, skate, lumpfish and undersized halibut, i.e., <81 cm. Licence conditions have since been used to enforce the regulation for the less than 65' fleets, making it mandatory to throw back small halibut whether dead or alive, and current conditions also require halibut to be landed complete with head and tail. However, for halibut landed with a head off length greater than 81 cm this condition is not enforced. For the less than 65' mobile gear fleet, once their halibut bycatch quota is taken, licence conditions require them to discard all Atlantic halibut regardless of size. The offshore fleet may release undersized halibut but currently is not required to do so by licence condition.

Commercial Landings

Halibut landings declined from 3,274 t in 1961 to 1,059 t in 1976 (Tables 1 and 2, Figs. 1a, b) but, between 1977 and 1985 landings increased steadily to a high of 4,031 t. Since 1985 total landings declined to 1,373 t in 1992, rose to 1,618 t in 1993 due to high landings by EU countries, then dropped again in 1994 to 1,106 t as foreign landings again declined. Foreign landings, especially in 3NO, increased considerably after 1982 (Fig. 2a). These foreign landings, reported by EA vessels, have a high interannual variability. Foreign landings are not accounted for under the current management plans.

Canadian domestic landings reached a peak in 1985 (3,531 t), declined to 1,189 t in 1993 and to 1,023 t in 1994 (Fig. 2c). Scotian Shelf landings for 1994 remained similar to 1993; however, the Southern Grand Banks fishery declined by about 50% (Fig. 2b). The 1988-1993 precautionary TAC of 3,200 t has never limited the fishery for any gear sector (Fig. 2c) with the

exception of the less than 65' mobile gear fleet bycatch fishery. The 1994 precautionary TAC of 1,500 t, was not fully caught as a result of some sectors not fully utilizing their allocations, but no sector fished unrestrained. Mobile gear fleets operated on a bycatch-only system and the <65' longline fleet took slightly over their allocation and could have taken more.

Although in the past 4X accounted for the largest proportion of the landings, in recent years (1989-1992) landings in 4X and 4W have been similar and together accounted for approximately 50% of Canadian landings for all areas. In 1993 landings in 4W dropped significantly from 380 t to 284 t, while 4X landings increased from 352 t to 391 t. In 1994 landings by area on the Scotian Shelf remained stable with 4V landings increasing slightly and 4W and 4X declining somewhat. The initial drop in 4W was likely the result of reduced effort due to the cod moratorium first imposed in 1993. Table 3 gives halibut landings by quarter and indicates that the Canadian fishery is prosecuted mainly in the spring and summer in 4VWX (Table 3a), and primarily in the spring in 3NOPs (Table 3b). Foreign landings (Table 3c, 3d) are incidental on the Scotian Shelf taken as bycatch in the silver hake fishery, while the EU prosecutes a spring and summer fishery in 3NO outside the 200 mile limit. Although not included in the stock area, 5Zc landings for 1994 were 23 t. According to the Management Plan, landings from 5Zc are counted against the quota even though 5Zc is not considered part of the official stock area.

Small vessels (tonnage class TC) 1-3 i.e. <150 grt using longline gear are the dominant fleet in the Scotian Shelf fishery accounting for over 70% of the landings (Table 4, Fig. 3 a). In 1994 over 90% of the Scotian Shelf landings can be attributed to this fleet. Landings by the less than 65' mobile gear fleets in 4X were restricted by their small allocation as they are not permitted to direct for halibut. Longliners also account for most of the Canadian landings in 3NOPs (Table 5, Fig. 3b). Landings in that area for both small and large longliners dropped significantly. This drop may be related to the closed directed cod fishery in 3NO for 1994.

Management

The 1994 landings were 457 t less than the TAC set. Fixed gear less than 65' fishing on the Scotian Shelf caught 103% of their allocation, while on the Southern Grand Banks only 42% of the allocation was taken. The mobile gear fishery by >65' boats, took less than 10% of their 294 t allocation. The less than 65' mobile gear fleet was the only other gear sector to exceed their allocation and their halibut fishery was closed on August 22, 1994. Quota allocations, associated catch for 1994, and pertinent licence conditions are presented in Table 6. Landings to March 31, 1995, reached 135 t similar to the 1994 spring fishery of 147 t. The 1995 TAC of 850 t under present allocations is very restrictive to the <65' fixed gear fleet and has resulted in a bycatch fishery for halibut in 1995.

With the introduction of a precautionary TAC in 1988, the halibut fishery has been regulated by quotas on five gear sectors: 1) fixed gear less than 65'; 2) mobile gear less than 65'; 3) fixed gear 65-100'; 4) mobile gear 65-100'; and, 5) all gear greater than 100'. Longliners are the only gear type vessels which direct for halibut, with the mobile fleets restricted to bycatch fisheries.

Allocations to these various fleet sectors were generally based on a five year catch history. Since 1984, special permits were given to inshore fixed gear vessels from Scotia-Fundy to allow the access to the halibut fishery in 3NO. A special allocation of cod, permits sufficient bycatch to pursue the halibut and hake fishery. Due to weather conditions Scotia-Fundy vessels got a late start in this fishery, and often the cod bycatch was limited depending on the amount taken by Newfoundland vessels earlier in the season. To remedy this situation, for the 1993 fishery, each sector's fleet had its own cod quota. Under 1994 management, no directed cod fishery was allowed in 3NO. The fishery was limited to a 5% or 1,250 kg cod bycatch, observer presence, and use of a #14 or greater hook was mandatory.

Industry Consultations

In discussions with industry in 1994 and early 1995, fishermen emphasized the large numbers of small halibut that were being released, and the potential high survival of these fish. They indicated that the release program may have had a negative impact on the commercial catch rates, especially since 1992 as enforcement improved. Fishers felt that although halibut stocks were low, the 850 t TAC recommended by the FRCC for 1995 was too low. They indicated that the large numbers of small halibut being released were a sign of increased abundance and should be taken into consideration when discussing declining catches. Industry groups are also considering a proposal to release large halibut greater than 57 kg, as well as for the less than 81 cm fish in order to protect and enhance the spawning stock, assuming that this would allow the more fecund animals to spawn.

Industry discussions also resulted in a cooperative Industry/Science tagging program being initiated. Groups of halibut fishermen from three areas (i.e., Shelburne, ENS and Cape Breton) have been supplied with tagging equipment, and will tag undersized halibut during the 1995 fishery. To date over 100 halibut have been tagged by the ENS group, with no recoveries recorded to date. Discussions with industry were held to try to improve halibut sampling along the Eastern Shore. Fishermen belonging to the FSRS have indicated a willingness to provide some supplementary information. This possibility will be investigated during 1995.

Commercial Catch Rates

A commercial catch per unit of effort (CPUE) series, based on halibut directed longline catch and fishing effort (in thousands of hooks), was estimated from zonal interchange format (ZIF) data for 1985 to 1994 for 4VWX, 4VWX&3NOPs and 3NOPs alone. For the years prior to 1985, data for 4VWX was provided from the 1987 assessment by Neilson *et al.* (1987), using regional data (Table 7, Fig. 4a). Catch data from all tonnage classes of longliners for the whole year was used in developing the series. It should be noted that prior to 1988, longline effort was collected as lines fished and since has been reported as thousands of hooks.

Commercial catch rates have declined gradually in the 4VWX area for the directed longline fishery in recent years while showing stability since 1990 for 3NOPs. For the stock area as a whole, catch rates reflect the decline in 4VWX where most of the fishery takes place. The sharp increase in the mid 1980s was thought to be due to the introduction of the more efficient circle hook.

The release of undersized halibut likely had a negative effect on these estimates of the commercial catch rates. Preliminary data on the release of small halibut from the Fishermen and Scientist Research Society (FSRS) indicated that the amount released could be as high as 25% by weight of the total, for the less than 65' longline fleet landings (Table 9). Although the numbers of vessels examined was small it does give some indication of the magnitude of the release of small halibut. The data from the FSRS will have to be investigated more thoroughly before it can be used to increase our estimates of catch rates.

With the reduced quotas in place for 1995, <65' fixed gear Management Harvesting Plans, only permit halibut to be fished as a bycatch, in order to allow their fishery to continue throughout the year. The absence of a directed halibut fishery will impact our ability to use the commercial catch rate series to assess the halibut stocks.

Commercial Fishing Effort

Total estimated effort derived by dividing total landings by the directed CPUE (Table 8, Fig. 4b) for the whole stock area has shown a declining trend from 1985 to 1992, and remained more or less stable between 1992 and 1994. For 4VWX, total effort increased between 1992 and 1994 while effort decreased during the same time period in 3NOPs. Thus the increased effort in the 4VWX area was largely compensated for by the decrease in effort in the 3NOPs area.

Size Composition of Commercial Landings

Very limited commercial sampling indicates that both longline vessels and mobile gear vessels less 65' are landing halibut greater than the 81 cm size limit (Figs. 5a, b). This change for mobile gear may be related to the use of dockside monitors for the ITQ fleet and better enforcement of the minimum size regulation. A total of seven halibut samples were collected for 1994 which was an improvement over previous years (Table 9). Nonetheless, sampling halibut landings continues to be difficult due to the small numbers landed, the difficulty handling the fish, and the practice of removing the head and tail prior to landing.

Observer length frequencies for catches of large otter trawlers (>65') indicate that halibut continue to be caught below the legal size (Fig. 5c). There is no requirement under the licence condition for the large offshore fleet to release undersized halibut. By regulation they may release them if they wish.

Geographical Distribution of Commercial Catches

Halibut catch distributions for the 1994 commercial longline fishery were compared to that for 1993. As available log book information was used the data are generally limited to the fishery distribution of the 45-65' fixed gear vessels, i.e., those that kept log books indicating positional information. It does not reflect the distribution of bycatches or that of the directed fishery by smaller longliners. The 4X fishery in 1993 was conducted in the Brown Bank area, while in 4VW it was a shelf edge and Gully fishery (Fig. 6). However, in 1994 no catches with associated positional information were reported from Browns Bank. This is likely due to no positional information being collected for vessels that reported to the Barrington Passage Monitoring Company and not the absence of fishing in that area.

Geographical Distributions of Research Vessel Survey Catches

Research vessel survey distributions of Atlantic halibut (1970-1992) were examined last year (Annand and Beanlands 1993). In the spring, halibut in 4VW concentrate along the shelf edge and in the deeper water in the vicinity of the Gully and along the edge of Western Bank. In 4X halibut are most concentrated near Baccaro and Browns Banks, and as well extend up into the Bay of Fundy. Fall distribution is similar although concentrations in the Bay of Fundy are reduced. Summer distributions show reduced concentrations overall, but with a similar pattern. These patterns remained similar over time including in 1993 and 1994. However, in both 1993 and 1994 fewer halibut were caught east of the Gully and along the edge in 4VSc (Fig. 7). Mean numbers per tow by strata for the summer survey are given in Table 11, and indicated that over time highest concentrations of halibut on the Scotian Shelf were found in strata 452 (The Gully), 463 (Emerald Basin) and 480 (Browns Bank).

Research Vessel Catch Rates

Mean numbers per tow (1970-1994) obtained from summer research vessel surveys on the Scotian Shelf (Table 12a, Fig. 8a) increased between 1970 and 1980 and subsequently declined to 1983. Since that time survey numbers per tow increased gradually to 1991 and declined thereafter. Spring and fall surveys (Table 12b, Fig. 8b) in 4VWX (1979-84) show a declining trend in numbers per tow to 1984, while the 4VW survey (1986-1995) was variable, with the 1995 survey point the lowest in the time series. Typically, the RV surveys catch very few fish making it difficult to interpret the results in terms of resource abundance. The survey gear catches a different size distribution of halibut (generally smaller) than those directed for in the longline fishery (Fig. 9). Thus, the survey catch rates may prove to be more useful as an indicator of recruitment to the commercial fishery rather than fishable biomass, but more data and analyses are necessary to evaluate this possibility.

Prognosis

Domestic landings have declined slightly to about 1,000 t in 1994. Catch rates declined gradually in recent years (about 15 % over the last five years) and total effort for the whole stock area remained relatively stable since 1992. Thus, a large scale redirection of fishing effort to halibut as a result of closures in other fisheries is not evident. The reduction in the TAC in 1995 to 57% of the 1994 level, if proportional allocations among fleet sectors remains the same, will be restrictive to the directed fishery and catches will likely be substantially less than 850 t. This reduction in catch from levels of 1,000 t in 1994 and 1,300 t on average over the last five years should be ample to reduce effective fishing effort, and thus fishing mortality substantially; as advised last year. Halibut is a long lived species and stock conditions in 1996 are not expected to be greatly different from those in 1995. It will be necessary to maintain present restrictions on the fishery for several years before it can be determined whether these are having the desired positive effects on stock status.
