THE STATUS OF THE ATLANTIC SALMON STOCK OF HUMBER RIVER/BAY OF ISLANDS, NEWFOUNDLAND, 1994
by

C.C. Mullins and D.G. Reddin<br>Department of Fisheries and Oceans<br>Science Branch<br>P.O. Box 2009<br>Corner Brook, Newfoundland<br>A2H 6 Z 6

${ }^{1}$ This series documents the scientific basis for the evaluation of fisheries resources in Atlantic Canada. As such, it addresses the issues of the day in the time frames required and the documents it contains are not intended as definitive statements on the subjects addressed but rather as progress reports on ongoing investigations.

Research documents are produced in the official language in which they are provided to the secretariat.
${ }^{1}$ La présente série documente les bases scientifiques des évaluations des ressources halieutiques sur la côte atlantique du Canada. Elle traite des problemes courants selon les échéanciers dictés. Les documents qu'elle contient ne doivent pas être considérés comme des énoncés définitifs sur les sujets traités, mais plutôt comme des rapports d'étape sur les études en cours.

Les Documents de recherche sont publiés dans la langue officielle utilisée dans le manuscrit envoyé au secrétariat.

#### Abstract

The total recreational catch of retained small salmon on the Humber River in 1994 was below the catch in 1992 and the 1987-1991 and 1953-1991 means. The recreational catch of released large salmon, however, was $10 \%$ above the 1992-1993 mean, 249\% above the 1987-1991 mean and 95\% above the 1953-1991 mean. The results of a creel survey conducted on the Big Falls segment of the Humber River indicated that the total recreational catch of retained small salmon in 1994 was approximately $63 \%$ greater than reported in traditional DFO catch statistics. The catch-per-unit-effort of small salmon recorded in the creel survey was less than for 1993 and 1991. The estimated total returns of small salmon to the Humber River in 1994, based on the stratified maximum-likelihood estimate was the lowest of returns since the closure of the commercial salmon fishery in the Bay of Islands but similar to the 1984-1989 mean. The estimate of large salmon returns was the second highest of the last three years and indicates an increase in survival of previously spawned 1 SW salmon. The potential egg deposition achieved on the Humber River in 1994 from small and large salmon was below the target requirement for conservation. Lower egg depositions in 1994 relative to 1992 and 1993 are attributed to lower spawning escapement in 1989. On the basis of the relationship between recruits and spawners on the Humber River in 1977-1994 it is anticipated that returns of small and large salmon in 1995 will be above the target spawner requirements.

## RÉSUME

Le nombre total de petits saumons de la rivière Humber capturés et gardés par les pêcheurs sportifs en 1994 était inférieur à celui de 1992 et aux moyennes de 1987-1991 et 1953-1991. Toutefois, les prises sportives de grands saumons remises à l'eau étaient supérieures de $10 \%$ à la moyenne de 1992-1993, de $249 \%$ à la moyenne de 1987 1991 et de $95 \%$ à la moyenne de 1953-1991. Les résultats d'une enquête auprès des pêcheurs sportifs qui pratiquent leur activité dans la partie de la rivière Humber située à Big Falls révélaient que les prises sportives totales de petits saumons gardées en 1994 étaient supérieures de $63 \%$ environ aux prises déclarées dans les statistiques traditionnelles du MPO. En ce qui concerne les petits saumons, les prises par unité d'effort estimées d'après l'enquête étaient inférieures à celles de 1993 et de 1991. Les montaisons totales de petits saumons dans la rivière Humber en 1994, fondées sur l'estimation stratifiée du maximum de vraisemblance, étaient les plus basses depuis la fermeture de la pêche commerciale du saumon dans la Bay of Islands et se comparaient à la moyenne de 1984-1989. Toutefois, les estimations de montaisons de grands saumons étaient parmi les plus élevées de celles des trois dernières années, arrivant au deuxième rang, et dénotent une hausse de la survie des saumons unibermarins à pontes multiples. La ponte estimée des grands et des petits saumons dans la rivière Humber en 1994 était inférieure à la cible établie pour la conservation. La diminution de la ponte par rapport à 1992 et 1993 est attribuée à une baisse des échappées de reproducteurs en 1989. En se fondant sur le rapport entre les recrues et les frayeurs dans la rivière Humber de 1977 a 1994, on anticipe que les montaisons de petits et de grands saumons en 1995 seront supérieures au niveau-cible de reproducteurs.

## INTRODUCTION

This is the fifth assessment of the Humber River / Bay of Islands area Atlantic salmon resource. This area is one of four river systems within the Gulf of St. Lawrence identified for a pilot study of the River/Zone Management Strategy. The Humber River is the largest river flowing into the Bay of Islands coastal area which is situated in western Newfoundiand at the northern limit of Salmon Fishing Area (SFA) 13 (Figure 1). Potential egg depositions from Atlantic salmon on the Humber River in 1990 and 1991 were $40 \%$ and $73 \%$, respectively, below target requirements (Chaput and Mullins 1991, 1992) indicating that the abumdance of salmon was less than the minimum levels for conservation. Atlantic salmon were exploited commercially in the Bay of Islands area until 1991 but this fishery was closed in 1992 to help rebuild declining stocks. Recreational fisheries in 1992 contimued to harvest salmon in 3 of the 4 tributaries within the bay but were limited by the quota on small salmon harvests which was implemented in all SFA 13 rivers. With the commercial fishery closed in 1992 estimated egg depositions were above the target spawning requirement for the first time in seventeen years.

The total drainage area of the tributaries flowing into the Bay of Islands is $8124 \mathrm{~km}^{2}$, which is $93 \%$ of the drainage area of Statistical Area L (Table 1) and $57 \%$ of SFA 13 drainage area. The Humber River comprises $95 \%$ of the Bay of Islands drainage area and flows into Humber Arm (Figure 1) at latitude $48^{\circ} 57^{\prime} \mathrm{N}$ and longitude $57^{\circ} 53^{\prime} \mathrm{W}$. The total length of all the streams in the Humber River is 2450.5 km . Complete obstructions to migrations of anadromous Atlantic salmon within the Humber River system occur at Main Falls (Figure 2) which is 112.6 kilometres from the river mouth and at Junction Brook which was diverted for hydroelectric development in 1925. The diversion of Junction Brook which flowed into the Humber River at Deer Lake, resulted in the loss to the Humber River system of the anadromous salmon production potential of the Grand Lake system (Porter et al. 1974) (see Figure 2). No fish passage facility was provided during the diversion to maintain upstream migration of fish stocks.

Several Atlantic salmon resource conservation measures have been imposed on the commercial and recreational fisheries since 1978 which have impacted on harvests within the Humber River / Bay of Islands area. The major conservation measures have included:

1. 1978 - commercial season shortened to June 1-July 10 from May 15-December 31.
2. 1984 - mandatory release of large salmon ( $\geq 63 \mathrm{~cm}$ fork length) in recreational fishery.
3. 1987 - recreational season bag limit of 15 small salmon ( $<63 \mathrm{~cm}$ fork length).
4. 1990-35 t commercial quota in SFA 13 commercial fishery.
5. 1991-25 t commercial quota in SFA 13; recreational season bag limit of 10 small salmon.
6. 1992 - five year commercial moratorium; recreational quota of 5,000 small salmon in SFA 13; recreational quota of 100 small salmon for Adies Lake (Figure 2); a catch and released fishery was permitted after the quota was reached; recreational season bag limit of 8 small salmon.
7. 1993 - recreational quota of 5,200 small salmon in SFA 13 (4,160 for June 5-July 31 and 1,040 for Aug.1Sept.6); daily bag limit of one fish; Cook's Brook was closed for the season.
8. 1994 - recreational season bag limit of 3 small salmon before July 31 and 3 after July 31; daily bag limit of 2 fish; daily catch and release limit of 4 fish.

The assessment of the status of the Humber River/Bay of Islands Atlantic salmon stock is based on the analysis of annual trends in recreational catches and the estimation of spawning escapement. Spawning escapement is estimated using derived exploitation rates in the recreational fishery applied to the total recreational harvests.

The present document provides the recreational catches and effort, and timing data for the Humber River / Bay of Islands for 1994. It follows the initial assessments presented for 1990, 1991, 1992, and 1993 (Chaput and Mullins, 1991; Chaput and Mullins, 1992; Mullins and Chaput, 1993; Mullins and Chaput, 1994 MS) and addresses the following topics:

1) verification by independent creel method, of the recreational catch statistics collected by the Department of Fisheries and Oceans (DFO) for the Big Falls segment of the Humber River,
2) estimation of the exploitation rate by the recreational fishery on small salmon in 1994 by mark-recapture methods,
3) updating of the biological characteristics of the Humber River/Bay of Islands Atlantic salmon stock for 1994,
4) examination of the effect of the 1994 management regulations on the spawning escapement to the Humber River,

## MATERIALS AND METHODS

## Recreational Fishery Statistics

The DFO catch statistics for the recreational fishery were compiled from river guardian and fisheries officer reports. The traditional methods used for summarizing these data are described in Mullins and Claytor (1989) and Mullins et al. (1989). Catch and effort for the Humber River are described by river segment (Figures $1 \& 2$ ) and the standardized weeks used are described in Table 2.

Salmon catches in the recreational fishery are categorized into small and large size groups. The criteria for small and large salmon designation are as follows:

| Small (Grilse; 1SW) | $<$ | $<63 \mathrm{~cm}$ fork length |
| :--- | :--- | :--- |
| Large (MSW) | $\quad$ | $\geq 63 \mathrm{~cm}$ fork length |

Observed catches have generally accounted for $80 \%$ of the total catch reported (Mullins and Claytor 1989).
In 1992 and 1993, weekly salmon angling reports were also completed for the catch and release fishery which was permitted after the SFA 13 zonal quota was reached.

## Creel Survey, Big Falls

A creel survey to determine the angling catch at Big Falls, Humber River, was conducted between 19 June and 5 September 1994. The Big Falls segment (Figure 2) was again selected for the survey because it is accessed by anglers from two points and the angling catches from this segment have averaged $38 \%$ of the total Humber River catch since 1986.

The 1994 creel survey was designed to enumerate all salmon landed at the Big Falls section of the Humber River. The two main locations used by anglers to exit the fishing area were monitored for a total of 16 hours per day from 0600 hrs to 2200 hrs . The clerks recorded the number of hours fished by each angler, the number of salmon retained and released, and the number of carlin tagged salmon recaptured. Clerks were instructed to maintain records completely independent of those kept by DFO Guardians.

## Estimation of Exploitation Rate

Tagging traps were operated in the estuary and at Boom Siding on the Humber River in 1994 (Figure 1). Small and large salmon were marked with individually numbered green Carlin tags and released from the two tagging traps. Tags were applied using a double stainless steel wire attachment, directly under the dorsal fin. All salmon captured in the two trap were measured (fork length 0.1 cm ), and scale sampled.

Estuary Trap - This trap has been fished in the same location at Wild Cove, Humber Arm (Fig. 1), since 1990. The trap design and installation in 1994 were identical to the 1990-1992 sampling program (Chaput and Mullins 1991, 1992; Mullins and Chaput, 1993).

Boom Siding Trap - This trap was fished for the first time in 1994 and was located about 10 km upstream from the estuary trap. The Boom Siding trap was a floating design and was operated in about 6 m water depth. The dimensions of the floating trap were 18.3 m length $\times 4.9 \mathrm{~m}$ width $\times 5.5 \mathrm{~m}$ depth and it was constructed of the same type 5.71 cm stretched mesh nylon as the lower trap.

The angling exploitation rate used to estimate the returns of small salmon to the river in 1994 was the number of tags recaptured by anglers, divided by the number of tags available in the population.

A summary of the equations used to calculate angling exploitation rate in 1994 are given in Table 3.
Exploitation Rate $(E R)=$ Tags Recaptured (TR) / Tags Available (TA)

## Estimation of Tags Recaptured

The proportion of recaptured tags that were actually returned by anglers in 1994 was estimated on the basis of recaptures reported by the creel survey clerks at Big Falls.

Reporting Rate $(R R)=$ Observed Tags Returned from Big Falls / Observed Tags Recaptured at Big Falls

$$
T R=\text { Total Tags Returned } / R R
$$

The ratio (tags/catch at Big Falls):(tags/catch for the rest of the river) does not give a valid estimate of the reporting rate because creel clerks did not observe $100 \%$ of the tags recaptured at Big Falls.

## Estimation of Tags Available

The total number of tagged small salmon available to anglers (TA) on the Humber River in 1994 was estimated by adjusting the number of tags applied for tags lost due to tag shedding after release. The tag loss rate (TL) was estimated based on the proportion of 0.009 tags shed per day to recapture derived for Margaree River in 1992 (Chaput et al. 1993). The method of tag application to salmon in the Margaree River tagging program is the same as for the Humber River. Median days to recapture were determined according to (Sokal and Rohlf, 1969). Tags available to anglers was estimated from the number of tags applied to small salmon multiplied by the proportion of tags retained (1-TL).

$$
T A=\text { Tags Applied } x(1-T L)
$$

Where:

Tag-Loss Rate $(T L)=(0.009$ tags/day $x$ Median Days to Recapture $)$

Injured fish were not tagged and no tagging was conducted at water temperatures above 20 C . Therefore, tagging mortality is believed to be negilible. All salmon tagged in the estuary trap in 1994 are assumed to be destined for the Humber River, however, some recaptures of tagged bright salmon were reported in the past from Hughes Brook.

## Estimation of Total Recreational Harvest

The total recreational catch of small salmon for the Humber River was adjusted based on the catch of small salmon recorded by the creel survey clerks at Big Falls and the proportion of the total angling catch taken at Big Falls.

## Adjusted Catch $(A C)=$ Catch at Big Falls (Creel) / Proportion at Big Falls

Two methods were used to estimate the proportion of the total river harvest angled at Big Falls: 1. the proportion of catch reported from Big Falls in the DFO catch statistics and 2. the proportion of tags returned from Big Falls. The average of these two values was used to determine the total catch.

Catches of small salmon recorded by the creel survey clerks at Big Falls were from immediately below (1-2 km ) the falls area and did not include the pools further downstream (Mistaken Point area) which were accessed via another route, but which would have been included in the Big Falls area of the DFO catch statistics (Fig. 3). As a result the catch recorded by the creel survey clerks at the falls was adjusted to give a catch for the entire Big Falls area. This was done based on the proportion of tags recaptured at the falls and in the Mistaken Point area. No tags were recaptured in the Big Falls area above the falls.

## Returns to the Humber River

The returns of small salmon to the Humber River were estimated by:

1. the Peterson (Single Census) method (Ricker, 1975) according to the formula

$$
\text { Returns of Small }(R S)=A C / E R, \text { and }
$$

2. a maximum-likelihood stratified design following the method of Dempson and Stansbury (1991) and Darroch (1961). Both estimates were based on the total adjusted catch of small salmon, adjusted tags available to angling, and adjusted recaptures.

For the maximum-likelihood estimate, tag releases and tag recaptures were initially stratified into six intervals. Release intervals were either two or three weeks, but all recapture intervals were two weeks. The original matrix was collapsed to reduce the number of intervals with zero releases or recaptures.

The returns of large salmon were determined by applying the ratio of large to small salmon captured in the two tagging traps to the estimate of small salmon returns where:

In the 1990 and 1991 assessments, the appropriate ratio of large to small salmon returns to the river was considered to be equivalent to the ratio of large to small salmon in the recreational fishery ( $7 \%$ ) prior to 1984 when large salmon could be retained (Chaput and Mullins 1991, 1992). However, a commercial fishery was also permitted in these years. Because of the closure of the commercial fishery in 1992 and the potential for an increase in the river escapement of large salmon, the ratio of large to small salmon captured at the tagging traps is considered to be more representative of returns to the river.

## Biological Characteristics

Biological characteristics of Humber River salmon in 1994 were obtained from bright salmon at the traps and from angling catches landed at the Big Falls segment of the Humber River. The fish were sampled for fork length $(0.1 \mathrm{~cm})$ and whole weight $(0.01 \mathrm{~kg})$ and sex determination was by internal examination except on live fish. Scale samples were obtained for determining the river-age and sea-age. These methods were identical to those used in 19901993.

## Estimation of Target Spawning Requirements

Target egg deposition for the Humber River was calculated using an optimal egg deposition for fluvial and lacustrine parr rearing area. In previous assessments (1990-1992) for the Humber, lacustrine area had not been included in calculating the target egg deposition. However, values of the percentage of the target achieved in those years which are presented in this document have been recalculated based on the adjusted target. The egg deposition rate used for fluvial area was $2.4 \mathrm{eggs} / \mathrm{m}^{2}$ as described by Porter and Chadwick (1983) and the egg deposition rate used for lacustrine area was 368 eggs/ha as described by O'Connell (1991). The fluvial parr rearing area for the Humber River has been estimated at $11,530,700 \mathrm{~m}^{2}$ (Porter and Chadwick 1983). The available lacustrine area was measured from 1:50,000 scale topographic maps using a dot grid.

## Estimation of Potential Egg Depositions

The potential egg depositions were calculated using the estimated spawning escapement and observed biological characteristics (mean weight of females, percent female, fecundity) of small and large salmon in 1994. The spawning escapement was obtained by subtracting the adjusted total recreational catch of small salmon retained from the estimated returns to the river.

Number of Recruits and Spawners, 197494, and Anticipated Returns in 1995
Reddin, et al. (in press) described a technique whereby it was possible to retrospectively construct total population size of small salmon (or total number of small salmon recruits) prior to any exploitation in selected rivers with counting facilities and to use the number of salmon recruits per spawner to estimate anticipated returns one year in advance. The technique is fully described in $\mathrm{O}^{\prime}$ Connell, et al. (in press) and equations used to derive recruits and spawners for the Humber River salmon stock are the same with the exception that large salmon are included (exploitation rate in commercial fishery $=0.80$ ).

## Analysis to Detect Recruitment Overfishing

Details on analyses to detect recruitment overfishing are provided by $\mathrm{O}^{\prime}$ Connell, et al. (in press).

## RESULTS

## Recreational Effort and Catches

The recreational angling season in the Bay of Islands opened on 4 June and closed on 5 September 1994. The Adies Lake quota of 100 small salmon was not reached but this segment closed on 31 July.

The recreational catch of small salmon in the Bay of Islands region in 1994, from DFO catch statistics, was $31.1 \%$ below the 1992-1993 mean, $38.5 \%$ below the $1987-1991$ mean and $46.5 \%$ below the 1953-1991 mean (Table 4). The proportion of the SFA 13 catch of small salmon taken in the Bay of Islands in 1994 was about the same as in 1992-1993 and 1987-1991, but 12.4\% above the 1953-1991 mean (Table 4). Released catches of large salmon in the Bay of Islands in 1994 were $19.1 \%$ above the 1992-1993 mean and $155.6 \%$ above the 1987-1991 mean.

Within the Bay of Islands region, recreational catches from the Humber River remained the dominant proportion of the total catch (Table 5). The catch of small salmon on the Humber River in 1994 was 1,550 fish, which was $30.2 \%$ below the catch in 1992-1993 and $39.5 \%$ below the 1987-1991 mean. Catches of small salmon on Goose Arm River which in 1993 were the highest ever recorded had dropped to $47.4 \%$ below the 1992-1993 mean, but were still above the 1987-1991 mean (Table 5).

Released catches of small salmon from the Humber River in 1994, were $23 \%$ of the total retained and released catches (Table 6). This was similar to 1993 when released catches were $27 \%$ of the total, but more than twice the value in 1992 ( $8 \%$ ). Observed effort and catch recorded by the DFO catch statistics were about $30 \%$ of the total.

The highest angling effort on the Humber River in 1994 was at Big Falls followed by the Lower Humber (Table 7a). The effort at Big Falls was $10.4 \%$ below the 1992-1993 mean, $18.6 \%$ above the 1987-1991 mean, but $6.3 \%$ below the 1977-1986 mean. The effort on the Lower Humber was $26.3 \%$ above the 1992-1993 mean (Table 7 a ).

The recreational catches of small salmon on six of eight segments of the Humber River were below those in 1993 (Table 7b). Only the Lower Humber and Adies Lake had higher catches than in 1993. Big Falls again produced the highest catches, but these were $45.3 \%$ below the 1992-1993 mean, and 31.5\% below the 1987-1991 mean. The catch at Big Falls in 1994 represented $42 \%$ of the Humber River catch compared to $40 \%$ in 1993, $63 \%$ in 1992, and an average of $50 \%$ in 1976-1991.

The highest released catch of large salmon was on the Lower Humber River which was $88.6 \%$ above the catch in 1992-1993 and 371.4\% above the 1987-1991 mean (Table 7b).

## Creel Survey Catches at Big Falls

A total of 3,839 anglers were interviewed or observed in the creel survey at Big Falls in 1994 (Table 8). Each angler fished for an average of 3.70 hours which was similar to the average effort expended in 1993, but $14.5 \%$ less than in 1992 (Table 8). The total catch observed was 765 small salmon retained and 436 released, and 63 large salmon released (Table 8). The catch of small salmon retained per unit of effort (CPUE) for interviewed anglers was the lowest in the three years that the survey was conducted (Table 8).

A total of 14 carlin tagged small salmon were observed by the creel clerks in 1994 (Table 8). Nine of these were subsequently returned voluntarily by anglers for a reporting rate of 0.64 which is similar to the rate of 0.75 which was assumed for the Humber River in 1993.

The distribution of weekly angling effort and catch of small salmon retained were similar for the creel survey and the DFO catch statistics (Table 9; Figs. 4, 5). Week 27 was the peak of angling effort and catch. However, the total catch of small salmon retained observed in the creel survey was $17.5 \%$ higher than the catch recorded in the DFO statistics (Table 9), even though the DFO records covered a larger area (Fig. 3).

## Estimation of Total Catch

The adjusted total catch of small salmon at Big Falls was 1,011 and the adjusted total catch for the Humber River was 2,523 (Table 10).

## Estimation of Exploitation Rate

The Estuary tagging trap was operated from 6 June to 1 September and the Boom Siding Trap operated from 1 June to 29 August 1994. A total of 81 large and 629 small bright salmon were captured in the Estuary and Boom Siding traps (Table 11). The ratio of large:small salmon captured in both traps in 1994 was $0.1288: 1$ which was more than twice the ratio of large:small salmon in 1992 (Table 12).

The peak catches of small salmon in the estuary occurred in mid-late June (Fig. 6a), whereas, the peak catches at Boom Siding occurred in early July (Fig. 6b). The peak of large salmon catches occurred about mid-June in both traps (Figs. 6a, 6b).

A total of 601 (426 estuary; 175 Boom Siding) small bright salmon and 81 (78 estuary; 3 Boom Siding) large salmon were tagged and released from the two traps (Table 13).

The peak of tag releases from the Boom Siding trap was in week 27 which was two weeks later than in the estuary trap (Fig. 8), and peak recaptures from angling of tags applied at Boom Siding was week 30, also about two weeks later than recaptures of those applied in the estuary trap (Figs. 9).

Tagged small salmon were recaptured by angling in each week of the fishery (Table 13) with the distribution of recaptures corresponding to the distribution angling catches (Fig. 10), indicating that tagged fish were evenly dispersed in the population and available to the fishery at the same time as untagged fish. However, tag recaptures at Big Falls did not correspond to angling catches in the first two weeks of angling (Fig. 11).

Tagging was not carried out at surface water temperatures above 20 C and the number of tags returned did not appear to be related to the water temperature at the time of tagging (Table 14).

Tags recaptures were recorded from all major segments of the Humber River (Table 15). The largest number of recaptures were at Big Falls (37) followed by Harriman's Steady (36). A total of 97 tags were returned from small salmon and 4 from large salmon (Table 16).

Five of the small salmon released from the estuary trap were subsequently recaptured in the Lower Humber River which is downstream from the trap at Boom Siding (Table 15).

The median number of days before recapture for tagged fish was 16.6 days (Table 17). This was similar to the mean number of days at large for tagged salmon in 1993. The minimum was 0 days and the maximum was 80 days. The estimated overall proportion of tags retained was $0.8380(1-(0.009 \times 18$ days $))$.

The minimum angling exploitation rate on Humber River small salmon in 1994, unadjusted for tag loss or tag reporting rate, was 0.1544 (92/596). This value was similar to the unadjusted rates derived for $1990(0.134), 1991$ (0.164), and 1993 (0.1455).

After adjustment for tag loss and reporting rate, the overall adjusted exploitation rate for 1994 was 0.2865 (Table 17). This was higher than the adjusted rates of 0.25 derived for 1990 and 1991, and 0.2213 in 1993. Angling exploitation was highest on salmon tagged and released during week 22-23 and ranged from 0.1731-0.7098 throughout the season, but tended to be lower towards the end of the season (Table 17). The range in exploitation rates derived for each two week period indicates that the fishery harvested certain portions of the returns more than others.

## Biological Characteristics

Small salmon captured in the traps in 1994 were primarily virgin one-sea-winter (1SW), whereas, large salmon were primarily repeat spawning 1SW fish. The mean fork length of small, 1SW salmon sampled from the tagging traps in 1994 was $53.58 \mathrm{~cm}(\mathrm{~N}=628)$ and the mean fork length of large, MSW salmon was 74.06 cm $(\mathrm{N}=82)$. The mean weight of small, 1 SW female salmon sampled in the recreational fishery was $1.70 \mathrm{~kg}(\mathrm{~N}=21)$ and the percentage female was $50.89(\mathrm{~N}=112)$ (Table 18 ). About $56 \%$ of the small, 1 SW salmon sampled at the traps and in the recreational fishery were smolt-age- 3 and about $42 \%$ were smolt-age -4 (Table 18).

## Returns and Escapements to the Humber River.

The Peterson (single census) method estimated 7,777 ( $95 \% \mathrm{CI}=6,600-9,158$ ) small salmon returns in addition to 295 fish angled in the Lower Humber River for a total of 8,072 small and 1,040 large salmon returns in 1994 (Table 19). The maximum-likelihood stratified estimate was $7,700(95 \% \mathrm{CI}=6,235-9,165)$ for a total of 7,995 small and 1,030 large salmon (Table 19). The potential spawning escapement was 5,549 small and 1,040 large salmon based on the Peterson estimate, and 5,472 small and 1,030 large based on the stratified estimate. The number of small salmon spawners in 1994 were well below the minimum requirement (Fig.11). Large salmon spawners were also below the target, but were the fourth highest since 1975 (Fig. 12).

The potential spawning escapements for 1994 from the Peterson and stratified estimates would have resulted in potential egg depositions which were $41 \%$ and $40 \%$, respectively, of the target spawning requirement (Table 20). Estimates of potential egg deposition from both estimates of returns in 1994 are below the 1992 and 1993 estimates, but the percent of the target achieved based on the stratified estimate of retums in 1994 was $25 \%$ below 1984-1991 mean (Table 21).

Atlantic salmon on the Humber River spend an average of three years in the river before migrating to sea (Table 18). In 1994, $56.5 \%$ of small salmon captured in the tagging traps had a smolt-age of 3 years, and $42.4 \%$ had a smolt-age of 4 years compared to $80 \%$ at smolt-age-3 in 1993. Ninety-seven percent of these fish had spent one year at sea before returning to spawn for the first time. Based on the time spent in the river and at sea, the majority of returns to the river in 1994 were the cohorts of spawners in 1988 and 1989. Spawners in 1989 were the lowest in recent years (Fig. 11). Given a similar age composition to 1994, returns of small salmon in 1995 will be the cohorts of spawners in 1989 and 1990. Returns in 1995, similar to 1994, may also be influenced by the low spawning escapement in 1989.

## Number of Recruits and Spawners, 1974-94, and Anticipated Returns in 1995

The outcome of calculations of total numbers of salmon recruits, numbers of spawners, and mumbers of recruits per spawner are shown in Figs. 13-17. The number of small and large salmon recruits and corresponding number of spawners for each year class are shown in Fig. 13. There was a lot of variability in recruitment from a given spawning escapement. Since 1974, there was a significant decline ( $r^{2}=0.40 ; \mathrm{df}=19 ; \mathrm{P}<0.01$ ) in the total number of small and large salmon recruits for Humber River (Fig. 14). Except for 1990, the lowest recruitment for the entire time series was experienced during the period 1989-1994. In fact, 1994 is the lowest.

There was no identifiable trend in the total number of small and large spawners (Fig. 14). Expressing target spawning requirement in terms of salmon adults (horizontal line in Fig. 14), it is evident that target spawners were achieved in 1975-1976 and 1992. Numbers of spawners in 1992-94 although declining over that period compare well with higher values in the past, particularly the late 1970s and early 1980s, and represent a substantial improvement over the lows observed for 1989 and 1991.

The total number of salmon recruits produced for each spawners showed no trend for small salmon ( $r^{2}=0.13 ; \mathrm{df}=14 ; \mathrm{P}>0.05$ ) (Fig. 15) but declined significantly for large salmon ( $\mathrm{r}^{2}=0.60 ; \mathrm{df}=13 ; \mathrm{P}<0.01$ ) (Fig. 16). The number of small and large salmon recruits anticipated for 1995, based on the average number of small and large recruits produced per spawner for each river age grouping, is approximately 17,000 small and large salmon (Fig. 17).

## Analysis to Detect Recruitment Overfishing

During the commercial fishery moratorium years 1992-1994, numbers of spawners in Humber River were above the replacement (diagonal) line (Fig. 18). In two of the three years immediately preceding the moratorium, 1989 and 1991, numbers of spawners were well below the replacement line. Of the total number of 15 data points, 8 were below.

## DISCUSSION

Recreational catches of small salmon on the Humber River declined in 1994 compared to the 1992-1993 mean, but increased in relation to the rest of SFA 13. This increase in the percentage of SFA 13 catches of small salmon taken in the Humber River/Bay of Islands region may be due to the low returns to the Bay St. George area of SFA 13 as indicated by low angling catches in 1994. Encouragingly, recreational catches of large salmon released in the Humber River/Bay of Islands area were above the 1992-1993 mean and substantially above the previous five years when there was great concern over declining large salmon stocks.

Recreational catch statistics indicated that the abundance of small salmon on the Humber River in 1994 were below 1992 and 1993 levels. The interpretation of the recreational data is confounded by the unknown effect of the changes in the daily bag limit over the last three years and the switch from zonal quotas to the split season in 1994. However, the conclusion of lower abundance of small salmon on the Humber River in 1994 is supported by low catches in other SFA 13 rivers and the lower CPUE in 1994 (0.27) compared to 1993 (0.31) and 1992 (0.36). The CPUE calculated from the creel survey results in 1994 was also lower than similarly derived CPUE in previous years. Similar to 1991, when catches were also low, there was little difference between the DFO and creel survey results in 1994. In contrast, it appears that in 1992 and 1993, when angling catches were higher and the discrepancy between the two estimates of catch at Big Falls was greatest, it was more difficult to obtain accurate catch data by the traditional methods. Based on the creel survey results in 1994, the total recreational catch of small salmon on the Humber River may have been about $63 \%$ higher than the estimate provided by DFO catch statistics. If this is true for other rivers then population sizes derived from catch statistics will be underestimated on these rivers.

The high effort on the Lower Humber River in 1994 compared to the 1992-1993 mean was probably due to the increase in catches of large salmon on this section of the river indicating an increase in the abundance of large salmon.

The Darroch (1961) stratified estimate of small salmon returns in 1994 and $95 \%$ confidence limits were almost identical to the Peterson estimates. However, there was some variation in recapture probabilities among the three recapture strata of the Darroch (Appendix 2). The mean of the Darroch recapture probabilities ( 0.2760 ) was very similar to the Peterson (Table 17). Pooling of several of the initial strata was necessary for the Darroch estimator and probably reduced the differences in recapture probabilities between the three collapsed strata. If the sample size had been large enough to maintain the initial number of strata, the stratified estimate of small salmon returns would have been an even more appropriate estimator than the single census estimate.

The stratified estimate of returns of small salmon to the Humber River in 1994 was $58 \%$ below returns in 1993, corresponding to lower spawning escapement in 1989 compared to 1988. However, returns in 1994 were also comprised of a large proportion of the 1988 cohort (river-age-4) which probably resulted in higher returns than would have been the case if the proportion of river-age-4 fish had been similar to 1993. If the survival in the river and at sea of the 1990 cohort is similar to that of the 1988 cohort then the return of small salmon to the Humber River in 1995 is anticipated to be above the 1994 level, and comparable to 1992 and 1993 (Fig. 12).

Large salmon on the Humber River in 1994 were primarily repeat spawning 1SW salmon which spawned for the first time in 1992. Returns of small salmon in 1992, the first year of the closure of the commercial fishery in the Bay of Islands, were the highest of estimates recorded for the Humber River indicating an increase in the sea-survival of previously spawning salmon. Supporting the conclusion of increased large salmon abundance in 1994.

Assuming no removals for recreational fishing, the anticipated spawning escapement for 1995 based on trend analysis will be above target by $40 \%$ for small salmon and below target by $37 \%$ for large. With removals of small salmon for the angling fishery similar to exploitation patterns in 1994, target spawners would be achieved in terms of small salmon only. The variability in recruitment described in Fig. 12 must be kept in mind with respect to estimates of anticipated returns.

In a stock with a healthy spawning population it is suggested that points in the spawner-recruit relationship described in Fig. 18 should fall above and below the line in a $50: 50$ distribution. Also, the points should fall above the target spawning line which in the case of the Humber only two years, viz. 1992 and 1993 do. We conclude from this that the Humber River salmon stock while being below target spawning in some years, is now in a position to increase in size.

In order to improve the accuracy of the mark-recapture technique in assessing the impact of the commercial closure on the Humber River Atlantic salmon resource, estimates of recreational catches have to be improved. One way to accomplish this would be to conduct an intensive creel surveys at Big Falls and other sections of the river in order to count all landings and ensure $100 \%$ reporting of all tags recaptured. Another improvement would be to obtain a complete count of small and large salmon returns to a portion of the river system using a counting fence or other technology.

## ACKNOWLEDEMENTS

Funding for the 1994 assessment project was provided in part by grants from the Canada/Newfoundland Agreement for Salmonid Enhancement and Conservation to Mr. W. Tucker for the operation of the two tagging traps in 1994, and to the Humber Valley Development Association for conducting the creel survey at Big Falls. We are grateful for thier continued support. As always, the support of DFO Conservation and Protection staff in Corner Brook and Deer Lake is also greatly appreciated.

## Appendix 2. Collapsed data and maximum-likelihood estimate of returns.

1Humber River Estimate, 1994 (adjusted for recaptures in Lower Humber)
OPooling in effect:

```
ROW 1 = (22-23,24-25)
ROW 2 = (26-27)
ROW 3 = (28-29)
ROW 4 = (30-31,32-34)
COL 1 = (25-26,27-28)
COL 2 = (29-30,31-32)
COL 3 = (33-34,35-36)
```

Input Data
$S=4, T=3$

The nc(i) vector is...
ROW 1
ROW 2
ROW 3
90.00
ROW 4
32.00

The $n r(j)$ vector is...
COL 1
COL 2
COL 3 1173.00 890.00 165.00

The marks never seen again are...
ROW 1
ROW 2
ROW 3
ROW 4 115.00
153.00
74.00
24.00

The $u(j)$ vector is...
COL 1
COL 2 840.00
COL 3 143.00

The m(i,j) matrix is...

COL 1

| ROW 1 | 43.00 |
| :--- | ---: |
| ROW 2 | 25.00 |
| ROW 3 | 2.00 |
| ROW 4 | .00 |

COL 2
4.00
5.00
32.00
9.00
11.00
3.00
3.00
5.00

## Appendix 2. (continued)

## Output Data

-----------

The E[m(i,j)] matrix is...

COL 1 COL 2 COL 3
4.20
28.90
15.83
2.89
5.27
8.09
4.42
4.81

The estimated stratification at recapture time...
COL 1 COL 2 COL 3 $3380.89 \quad 3613.20 \quad 695.68$

The probability of recapture estimates...

| COL 1 | COL 2 | COL 3 |
| ---: | ---: | ---: |
| .3469 | .2463 | .2372 |

Log likelihood $=\quad i 629.11$
Estimated population size (std. err.) $=7700.26$ ( 747.61)
G2 goodness of fit $=3.739535 \quad \mathrm{X} 2$ goodness of fit $=3.526996$
End of run -..-........

[^0]:    The equations were solved 5000 times to generate the distribution from which confidence limits were determined

[^1]:    * No adjustment is mada for tagged sadmon not dessined for the Humber River
    ** Five tagsrecaptured on between the two trapnets (on the lower Hunber) are not induded in
    the the analysis.

[^2]:    * Adjusted for mean reporting rate of0.64.
    ** Adjusted for tag loss based on 0009 tags/day.

[^3]:    Figure 4. Com parison of weekly angling effort obta ined by DFO and Creel methods.

[^4]:    Figure 7. Timing of tags releases at the Estuary and Boom Siding tagging traps, 1994.

[^5]:    Figure 10. Tming of catches of small salmon retained and tag recaptures at Big Falls, 1994.
