# Status of Atlantic Salmon (Salmo salar L.) Stocks of the Newfoundland Region, 1994 

by<br>M. F. O'Connell, J. B. Dempson, C. C. Mullins, D. G. Reddin,<br>N. M. Cochrane, and D. Caines<br>Science Branch<br>Department of Fisheries and Oceans<br>P. O. Box 5667<br>St. John's, Newfoundland A1C 5X1

${ }^{1}$ This series documents the scientific basis for the evaluation of fisheries resources in Atlantic Canada. As such, it addresses the issues of the day in the time frames required and the documents it contains are not intended as definitive statements on the subjects addressed but rather as progress reports on ongoing investigations.

Research documents are produced in the official language in which they are provided to the secretariat.
${ }^{1}$ La présente série documente les bases scientifiques des évaluations des ressources halieutiques sur la côte atlantique du Canada. Elle traite des problèmes courants selon les échéanciers dictés. Les documents qu'elle contient ne doivent pas être considérés comme des énoncés définitifs sur les sujets traités, mais plutôt comme des rapports d'étape sur les études en cours.

Les Documents de recherche sont publiés dans la langue officielle utilisée dans le manuscrit envoyé au secrétariat.

#### Abstract

The five-year moratorium on the commercial Atlantic salmon fishery in insular Newfoundland entered its third year in 1994. There were also further reductions in effort and quotas in Labrador. The moratorium placed on the Northern Cod Fishery in 1992, which should have eliminated by-catch of Atlantic salmon in cod fishing gear in Salmon Fishing Areas (SFAs) 1-9, continued in 1994. A moratorium on cod fishing was also introduced in SFAs 11-14A in August 1993 which continued in 1994. Although there appears to have been some improvement in returns of small and large salmon for SFAs 1 and 2 in Labrador in the past few years, estimated total population sizes were low compared to the late 1970s and early 1980s, years when there was a substantial commercial fishery. There was a marked decline in recreational catches of small and large salmon in southern Labrador (SFA 14B) in 1994 and the commercial fishery quota was not caught. Commercial and recreational catches (retained plus released fish) of small and large salmon and recreational catch rates were among the lowest on record in 1990 and 1991 in Labrador, and if indicative of spawning escapements, future returns could be low relative to 1994 should natural survival rates remain the same. Many rivers in SFAs 6-10 in insular Newfoundland were closed to angling for most of July in 1994 due to low water levels and high water temperatures. Recreational catches (retained plus released fish) of small salmon and catch rates during the moratorium years 1992-94 increased over the 1984-89 and 1986-91 means for Northern Peninsula and Eastern (SFAs 14A, 3-8) rivers, but were comparable to or lower than levels observed in some pre-salmon moratorium years. Also, although counts of small salmon at several counting facilities were significantly higher in 1992-94 than in 1986-91, counts similar to or greater than those of 1992-94 occurred in certain pre-salmon moratorium years. Returns of small salmon to counting facilities for SFAs 9-11 (South) in 1992-94 were low relative to pre-salmon moratorium years. Smolt-to-adult survival back to the river for Northeast Brook, Trepassey improved in 1994 but remained as low as when there was a commercial fishery. The situation for Conne River worsened. This is suggestive of high or above average natural mortality at sea in 1992-94 for these rivers and probably for southern Newfoundland rivers in general. Recreational catches (retained plus released fish) for SFAs 12-13 (Southwest) during the salmon moratorium years were well below those recorded for several premoratorium years. Low returns to rivers in SFA 13 (St. George's Bay) resulted in the closure of rivers to angling after August 8. Levels of recreational catches and returns to counting facilities, in the absence of commercial fisheries, suggest overall population sizes of small salmon for insular Newfoundland in 1992-94 were low relative to pre-salmon moratorium years. Angling data and counts of small salmon at several counting facilities indicate that in general, spawning escapements were low during 1989-91. This suggests that returns to Northern Peninsula and Eastern rivers in 1995 could be lower than in 1992-94 and returns to South and Southwest rivers could continue at the low levels indicative of the past few years, if natural survival rates remain the same. Returns of large salmon in insular Newfoundland in 1992-94 increased over the 1986-91 mean overall, but there were pre-salmon moratorium years when returns were higher.

## Résumé

Le moratoire quinquennal sur la pêche commerciale du saumon de l'Atlantique dans l'île de TerreNeuve en arrivait à sa troisième année d'existence en 1994. Au Labrador, il s'accompagnait d'autres réductions de l'effort et des quotas. Le moratoire imposé en 1992 sur la pêche de la morue du Nord, qui aurait dû éliminer les prises accidentelles de saumon de l'Atlantique par les engins de pêche de la morue dans les zones de pêche du saumon (ZPS) I à 9, demeurait lui aussi en vigueur en 1994. Était également en vigueur un autre moratoire sur la pêche de la morue, imposé dans les ZPS 11-14A en août 1993. Quoiqu'il semble y avoir une certaine amélioration dans les montaisons de petits et de grands saumons dans les ZPS 1 et 2 (Labrador) ces dernières années, les estimations d'effectif total étaient basses comparativement à la fin des années 1970 et au début des années 1980, années durant lesquelles existait une importante pêche commerciale. Les prises de petits et de grands saumons par les pêcheurs sportifs dans le sud du Labrador (ZPS 14B) en 1994 accusaient une nette diminution, et le quota de la pêche commerciale n'a pas été capturé. Les prises commerciales et sportives (prises gardées plus prises remises à l'eau) étaient parmi les plus basses enregistrées en 1990 et 1991 au Labrador. Si elles sont révélatrices des échappées de reproducteurs et que les taux de survie naturelle restent les mêmes, les montaisons futures pourraient être faibles par rapport à celles de 1994. Dans de nombreuses rivières des ZPS 6 à 10, dans l'île de Terre-Neuve, la pêche sportive était fermée durant la plus grande partie de juillet 1994, en raison des faibles niveaux d'eau et des températures élevées de cette dernière. Les prises sportives (prises gardées plus prises remises à l'eau) de petits saumons et les taux de prises au cours des trois premières années du moratoire (1992-1994) ont augmenté par rapport aux moyennes de 1984-1989 et de 19861991 dans les rivières de la péninsule nord et de l'est (ZPS 14A, 3-8), mais étaient comparables ou inférieures aux résultats obtenus durant certaines des années qui ont précédé le moratoire sur la pêche du saumon. Par ailleurs, quoiqu'en plusieurs endroits les dénombrements de petits saumons aient été très supérieurs à ceux de 1992-1994 et 1986-1991, des dénombrements du même ordre, voire plus élevés, avaient été obtenus au cours de certaines des années qui ont précédé le moratoire sur la pêche du saumon. Les montaisons de petits saumons aux installations de dénombrement des ZPS 9-11 (sud) en 1992-1994 étaient basses par rapport à celles des années ayant précédé le moratoire. Le taux de survie du stade de saumoneau à celui d'adulte retournant à sa rivière s'est amélioré en 1994 pour ce qui est du ruisseau Northeast, Trepassey, mais demeurait aussi faible qu'à l'époque de la pêche commerciale. Dans le cas de la rivière Conne, la situation a empiré. Cela dénote une mortalité naturelle en mer élevée ou supérieure à la moyenne en ce qui concerne les stocks de ces deux rivières et probablement ceux des rivières de l'ensemble du sud de Terre-Neuve. Depuis le début du moratoire sur la pêche du saumon, les prises de la pêche sportive (prises gardées plus prises remises à l'eau) dans les ZPS 12-13 (sud-ouest) ont été bien inférieures à celles obtenues durant plusieurs des années qui ont précédé le moratoire. Les faibles montaisons dans les rivières de la ZPS 13 (baie St. George) ont entraîné la fermeture de la pêche sportive dans ces rivières après le 8 août. Les résultats de la pêche sportive et les montaisons aux installations de dénombrement, en l'absence de pêche commerciale, révèlent que, dans l'ensemble, l'effectif des petits saumons dans l'île de Terre-Neuve de 1992 à 1994 était faible par rapport aux années qui ont précédé le moratoire. Selon les données de la pêche sportive et des dénombrements en plusieurs endroits, il apparaît aussi que les échappées de reproducteurs étaient généralement faibles de 1989 à 1991. Il en ressort que, si les taux de survie naturelle demeurent inchangés, les montaisons dans les rivières de la péninsule nord et de l'est en 1995 pourraient être inférieures à celles de 1992-1994, et que les montaisons dans les rivières du sud et du sudouest pourraient rester aussi basses que celles des quelques dernières années. Les montaisons de grands saumons dans l'île de Terre-Neuve en 1992-1994 ont augmenté par rapport à la moyenne générale de 19861991, mais on a connu des montaisons plus élevées au cours des années qui ont précédé le moratoire sur la pêche du saumon.

## Introduction

This paper presents the general status of Atlantic salmon stocks of the Newfoundland Region in 1994 (Fig. 1). Catch and effort data for the commercial (Labrador only) and recreational fisheries and counts of Atlantic salmon at fishways and counting fences are examined in relation to historical data and management measures in effect in 1994. Previously, 1983-93, assessments for Salmon Fishing Areas (SFAs) 12-14 were presented in separate documents.

## MANAGEMENT MEASURES

In 1992, a five-year moratorium was placed on the commercial fishery in insular Newfoundland, while in Labrador, fishing continued under quota or allowance catch. In addition, a commercial license retirement program went into effect in both insular Newfoundland and Labrador. The implementation of the moratorium on commercial fishing in 1992 followed a major management plan introduced in 1984 (O'Connell et al. 1992a; May 1993; Mullins and Caines MS 1994), elements of which were continued into the quota years of 1990 and 1991 and the 1992-94 moratorium years. These regulations continue a long standing history of implementation of management programs to prevent stock declines and allow populations to rebuild (May 1993).

## Commercial fishery

Quotas/allowance catches (t) for SFAs 1, 2, and 14B in Labrador in 1994 and since they were first introduced in 1990 were as follows:

| YEAR | SFA |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | $\mathbf{1}^{*}$ | $\mathbf{2}$ | $\mathbf{2 A}$ | $\mathbf{2 B}$ | $\mathbf{1 4 B}$ |  |
| 1990 | 80 | 200 |  |  | $50+10^{* *}$ |  |
| 1991 | 80 | 200 | 65 | 135 | 15 |  |
| 1992 | 80 | 180 | 60 | 120 | 13 |  |
| 1993 | 80 | 90 | 27 | 63 | 8 |  |
| 1994 | 24 | 60 | 20 | 40 | 8 |  |

*Allowance catch.
**The 1990 quota of 50 t was for all of SFA 14 ; there was also a supplementary quota of 10 t for SFA 14B.

In 1994, as in previous years, it was illegal to retain Atlantic salmon caught as by-catch and the mandatory carcass tagging program remained in effect. The commercial fishery opened on June 5 and closed on October 15.

The numbers of commercial fishers for each SFA in Labrador and for SFAs combined for the period 1974-94 are shown in Table 1. Each fisher was licensed to fish 366 m of gear.

## Recreational fishery

In 1992 and 1993, the number of fish that could be retained in each SFA was limited by quota. The quota was assigned for each SFA as a whole and not administered on an individual river basis. Only hook-and-release fishing was permitted after the quota was caught in each SFA. Quotas were eliminated in 1994. In insular Newfoundland, the season bag limit for the retention of small salmon in 1994 decreased from eight to six, three to be caught prior to July 31 and three after that date. After the bag limit of three was reached in each time period, hook-and-release fishing only was permitted. As in previous years, the retention of large salmon was not permitted in insular Newfoundland. In Labrador, there was no division of the bag limit before and after July 31. The season bag limit for large salmon was reduced from four to two. In both insular Newfoundland and Labrador, the maximum number of fish that could be retained per day increased to two. The maximum number of fish that could be hooked and released remained at four; anglers could continue to hook and release after the bag limit of one retained fish per day was reached.

On a river-specific basis, Conne River (SFA 11) was closed to angling in 1994 and there was no First Peoples' food fishery. Rocky River and Colinet River in SFA 9 were also closed. In SFA 13, seven rivers were managed by river-specific quotas; the same applied to three rivers in SFA 14A. Only hook-and-release fishing was permitted after river quotas were caught.

Seventy-two rivers throughout insular Newfoundland were closed to angling for varying periods in 1994 due to high water temperatures and low water levels (Table 2). Most of the rivers affected and the longest closure periods were mainly in SFAs 6-10. In SFA 13, eight rivers were closed (Table 2) after an in-season review in July, which indicated total returns for 1994 would be less than $50 \%$ of target requirement.

For the five-year period immediately preceeding the commercial salmon fishery moratorium, the average number of recreational fishery licenses sold in Newfoundland and labrador was 24493. Maximum license sales were recorded in 1988 (26445). By comparison, sales during the moratorium years were 25718 (1992), 26508 (1993), and approximately 23,000 (1994).

## PUBLIC CONSULTATIONS

In 1994, in addition to the usual consultative and advisory meetings involving organized user groups and representatives of the Provincial Government, the Department of Fisheries and Oceans
held several meetings with the public at large throughout Newfoundland and Labrador. The purpose of these meetings was to give the general public the opportunity to input into the stock assessment process. A description of the process and highlights and opinions expressed at each meeting are presented in Appendix 1.

## Methods

Commercial and recreational fishery catch and effort data and fishway and counting fence data were added to that presented in O'Connell et al. (MS 1994) and Mullins and Caines (MS 1994). For the Labrador commercial fishery, data were compiled by the Statistics and Informatics Branch of the Department of Fisheries and Oceans (DFO) in the manner described by Ash and O'Connell (1987a and b).

The monitoring of Labrador commercial fishery quotas in 1994 was similar to 1991-93. Landings were deducted from the quota of the SFA containing the fishers home port. However, for comparison with previous years when there were no quotas, landings in quota years were compiled by place landed. Commercial catches in the communities of Carrol's Cove, Camp Islands, and Cape Charles were deducted from the quota for northern Labrador (SFA 2, north of Cape Charles) in 1992-94. However, these catches were included as part of the SFA 14B catch statistics, as in previous years.

Recreational fishery data were compiled as described by Ash and O'Connell (1987a and b) and Mullins and Claytor (1989). Catch statistics for both retained and released small salmon were used in 1992-94. For SFAs 12-14, catch information for released large salmon has been available since 1985. Recreational fishing effort was presented as rod days, defined as any day or part of a day on which an angler fishes.

Means and $95 \%$ confidence intervals for ratios were calculated according to Cochran (1977).

Impacts of the commercial fishery moratorium on river escapements were assessed by analyzing recreational fishery data and counts of small and large salmon at fishways and counting fences. With respect to counts, three years of data are now available for the moratorium period. A nonparametric randomization ratio test was proposed by the North Atlantic Salmon Working Group of the International Council for the Exploration of the Sea (Anon. MS 1993) as a statistical means of evaluating short-term changes in salmon abundance such as this. The method consisted of computing the ratio of the means of counts for two periods of time (pre-moratorium and moratorium periods) to determine if the observed value is simply a random ordering of observations achieved by chance, or if the observed value is unlikely (Anon. MS 1993). The latter could imply a true change in abundance. Following the terminology of Rago (MS 1993), let $Y_{k, t}$ be the abundance (count) of salmon at index site ' $k$ ' and time ' $t$ '. The pre-moratorium period consists of ' $m$ ' observations while the moratorium period has ' $n$ ' observations. $R_{o}$ is the ratio of the means for the two periods:

$$
R_{\circ}=\frac{\sum_{k=1}^{K} \sum_{t=m+1}^{m+n_{k}} \frac{Y_{k, t}}{n_{k}}}{\sum_{k=1}^{K} \sum_{t=1}^{m_{k}} \frac{Y_{k, t}}{m_{k}}}
$$

Data from eleven rivers (Torrent River, Western Arm Brook, Exploits River (Bishop's Falls), Gander River (counting fence), Middle Brook, Terra Nova River, Biscay Bay River, Northeast Brook (Trepassey), Rocky River, Northeast River (Placentia), and Conne River) were used. Separate analyses were carried out on south coast rivers (SFAs 9-11) and Northern Peninsula and Eastern rivers (SFAs 14B, 4, and 5). The ratio test was used to compare returns of small and large salmon separately for the pre-moratorium period 1986-91 with returns in 1992-94. Two thousand permutations of the data were run.

Counts of small and large salmon for these rivers were also compared on an individual river basis. Comparisons of mean counts were made between the same moratorium and pre-moratorium periods using the GLM Procedure of SAS (SAS Institute 1985). Analyses were performed on rank transformed data (Conover 1980; Conover and Iman 1981) using the Rank Procedure of SAS.

For a number of rivers, partial counts of small and large salmon for certain years were adjusted to total counts. The rivers involved were Gander River and Salmon Brook (O'Connell et al. MS 1995a), Biscay Bay River (O'Connell et al. MS 1995b), and Sandhill River (Reddin et al. MS 1995).

As described in past years ( $O^{\prime}$ Connell et al. MS 1993, MS 1994), an index of fishing effort is available for the commercial Atlantic salmon fishery at Nain, north Labrador (SFA 1), and is defined as person-weeks fished (Dempson and Shears MS 1992). This is a shore-set fixed surface gillnet fishery largely carried out at traditional fishing berths. Catch and effort data from four subareas (Dog Island, Black Island, Kigalpaits, and Cutthroat), which contribute $92 \%$ of the Nain Fishing Region total salmon catch, were analyzed using a multiplicative model (Gavaris 1980) to account for differences in catch rates among years and weeks:

$$
Y_{i j}=\mu+\alpha_{i}+\beta_{j}+\epsilon_{i j}
$$

where $Y_{i j}$ is the response variable, standardized catch rate, $\alpha_{i}$ and $\beta_{j}$ are class variables year and week, respectively, and $\epsilon_{\mathrm{ij}}$ is the error term. For this analysis, the original four subareas were collapsed into two: Dog Island with Black Island, and Kiglapaits with Cutthroat, and analysed separately. Weeks were collapsed as follows: Standard Weeks 27-29 were grouped and also weeks 34 to the end of the season. The regression of $\ln$ catch rate for the period 1977-94 was initially fitted using SAS Reg procedures (SAS 1985) to avail of various diagnostic techniques. Back-transformed standardized catch rates were obtained using a bias correction process which was also run in SAS.

Analyses were conducted to determine if large salmon (2SW) stocks in SFAs 1 and 2, Labrador, were subject to recruitment overfishing. Sutherland (1990) and Anon. (MS 1994) defined recruitment overfishing as a level of fishing mortality that reduces the ability of a population to persist. Two forms were listed:

1) Spawning target overfishing, which is a reduction in spawning numbers below target levels as a result of fishing activities;
2) Spawner overfishing, which is failure of a cohort of spawners to replace itself as a result of fishing.

One way of evaluating Atlantic salmon stocks for both of these conditions is through the examination of spawner-to-spawner relationships. Estimated numbers of spawners obtained from parental spawning cohorts of a sea-age group were traced backward over all years in which fish of the same sea age returned, beginning with the estimate of the number of spawners for the current year. Data sets were examined to see if numbers of spawners, which were made up of a range of chronological ages, were sufficient to replace the weighted sum of parents of the same sea age. The appropriate weighting for historical spawners was determined from the average smolt-age distribution. In order to conclude that overfishing was the sole cause of failure to produce enough spawners in successive generations, natural mortality was assumed to be constant over the time series. For some rivers, natural mortality has been shown to be variable (see below). This technique, the necessary lags, target spawning requirement for SFAs 1 and 2, and river-age distributions for each SFA, are found in Anon. (MS 1994). Catch series information was updated for the present analyses.

## Results and Discussion

## THE LABRADOR COMMERCIAL FISHERY

The commercial catch of small salmon ( 7 t ) in SFA 1 in 1994 (Table 3 and Fig. 2a) was the same as in 1993 and it decreased from the 1984-89 (77\%) and 1986-91 (71\%) means. The catch of large salmon in 1994 ( 16 t ) declined from 1993 and the means ( 6,78 , and $73 \%$, respectively) (Table 3 and Fig. 2b). In SFA 2 (Table 4 and Fig. 2a), the 1994 catch of small salmon ( 9 t) decreased from 1993 and the means ( 61,88 , and $89 \%$, respectively). The catch of large salmon ( 54 t ) in 1994 in SFA 2 (Table 4 and Fig. 2b) increased over 1993 (17\%) but remained below the 1984-89 (63\%) and 198691 ( $60 \%$ ) means. In SFA 14B, the catch of small salmon ( 2 t ) (Table 5 and Fig. 2a) in 1994 was identical to that of 1993 which was below both means ( 86 and $87 \%$, respectively). The catch of large salmon ( 4 t) in SFA 14B (Table 5 and Fig. 2b) was below 1993 ( $76 \%$ ) and both means ( $86 \%$ ). For all SFAs in Labrador combined (Table 6 and Fig. 2a), the catch of small salmon ( 18 t ) in 1994 decreased from 1993 ( $44 \%$ ) and both means ( $85 \%$ ). Large salmon catch ( 74 t ) also declined from 1993 and the means ( 8,70 , and $67 \%$, respectively) (Table 6 and Fig. 2b). In all cases above, catches of both small and large salmon in 1994 were below the lower limit of the $95 \%$ confidence interval of both means.

Total commercial catch ( 22 t) in SFA 1 in 1994 (Table 3 and Fig. 2c) decreased from 1993 ( $12 \%$ ) and the 1984-89 (78\%) and 1986-91 (74\%) means. Likewise, for SFA 2 (Table 4 and Fig. 2c), the catch in 1994 ( 64 t ) decreased from 1993 and the means ( 6,71 , and $70 \%$, respectively). In SFA 14B, total catch ( 6 t ) was below 1993 ( $68 \%$ ) and both means ( $86 \%$ ) (Table 5 and Fig. 2c). For all of Labrador (Table 6 and Fig. 2c), total catch ( 92 t ) in 1994 decreased from 1993 by $18 \%$ and from the means by $75 \%$ (1984-89) and $73 \%$ (1986-91). For all SFAs separately and combined, total catches in 1994 were the lowest recorded and all were below the lower limit of the $95 \%$ confidence interval of each mean.

The percentage of quota caught and quotas (in parantheses) in 1990-94 were as follows:

| YEAR | SFA 1 | SFA 2 | SFA 14B | SFAS 1, 2, <br> \& 14B |
| :---: | :---: | ---: | ---: | ---: |
| 1990 | $65(80)$ | $64(200)$ | $38(60)$ | $59(260)$ |
| 1991 | $13(80)$ | $38(200)$ | $227(15)$ | $41(295)$ |
| 1992 | $83(80)$ | $67(200)$ | $131(13)$ | $75(273)$ |
| 1993 | $31(80)$ | $76(90)$ | $238(8)$ | $63(178)$ |
| 1994 | $92(24)$ | $107(60)$ | $75(8)$ | $100(92)$ |

In 1994, the quota was nearly caught in SFA 1 and exceeded in SFA 2; the quota was not caught in SFA 14B. It should be noted that quotas in 1993 (except for SFA 1) and to a greater extent in 1994, were substantially lower than in previous years.

Large salmon with river ages greater than 3 years are principally from stocks in Labrador and the Quebec North Shore (Reddin and Porter MS 1988). Commercial landings (No.) of large salmon in Labrador in 1974-93 (SFAs 1-2 and SFA 14b combined) in year $t$ were significantly correlated ( $\mathrm{r}^{2}$ $=0.57 ; \mathrm{df}=17 ; \mathbf{P}=0.0002$ ) with landings at West Greenland of North American-origin small salmon with river age greater than 3 years in year $t-1$ (Fig. 3). The time series of landings, for small and large salmon in SFAs 1,2 , and 14 b combined and North American-origin small salmon with a river age of greater than 3 years at West Greenland were all tri-modal with declining trends (Fig. 4). The declining trend for small salmon was significant $\left(\mathrm{r}^{2}=0.31 ; \mathrm{df}=19 ; \mathrm{P}=0.01\right.$ ) (Fig. 4a). The relationship between large salmon and year was significant ( $\mathrm{r}^{2}=0.77 ; \mathrm{df}=19 ; \mathrm{P}=0.0001$ ) (Fig 4b) as was the relationship between North American-origin small salmon with river age greater than 3 years and time ( $\mathrm{r}^{2}=0.43 ; \mathrm{df}=18 ; \mathrm{P}=0.0005$ ) (Fig. 4 c ).

The significant relationship between catches of large salmon in Labrador and catches at West Greenland of North American-origin small salmon with river age greater than 3 years, indicates that as the abundance of a smolt class changes there is a corresponding change in recruitment to the fisheries (Anon. MS 1991). The decline in catches of large salmon in Labrador and North American-
origin small salmon of river age greater than 3 years at West Greenland is indicative of a decrease in population size.

Landings of Atlantic salmon from the Nain Fishing Region, SFA 1, are available since 1977 (Dempson and Shears MS 1993). This catch series is the only one from which an index of fishing effort, and hence catch rate as an index of abundance, was obtainable. Catches ranged from a high of $60 t$ in 1980 (all subareas) to a low of $2 t$ in 1993 and again in 1994. Over the 15 year period 1977-91, the Nain Fishing Region represented about 31\% of the total SFA 1 catch of Atlantic salmon, and catches at Nain were associated with landings from the rest of Labrador ( $r^{2}=0.63, \mathrm{P}=0.004$, $\mathrm{N}=15$ ). Catches from all subareas averaged about $30 \mathrm{t}^{\bullet} \mathrm{y}^{-1}$ until 1990. During the past four years
 Cutthroat subarea dominated the catch series, averaging about $63 \%$ of the total landings at $19 \mathrm{t} \bullet \mathrm{y}^{-1}$ until 1989.

The regression of $\ln$ catch rate for the period 1977-94 explained $50 \%$ of the variation in the data for the Dog Island-Black Island area ( $\mathrm{F}=10.26 ; \mathrm{P}=0.0001$ ) (Table 7). Catch rates for the Dog Island-Black Island area declined from 1977 to 1979 folowed by an increased abundance in 1980. Abundance then declined until 1987 (Fig. 5). Abundance increased until 1989 but again declined rapidly up to 1993. In 1994, however, catch rates increased suggestive of higher abundance, but were still well below the long-term average (Fig. 5).

In the more northern Kiglapaits-Cutthroat area, only $25 \%$ of the variation in catch rates was explained by the model ( $\mathrm{F}=2.82 ; \mathrm{P}=0.0001$ ) (Table 7). Catch rates were quite variable (Fig. 5). The highest catch rate occurred in 1989 but this was also followed by a rapid decline in Abundance with the lowest levels occurring in recent years (Fig. 5). In both combined area groups (Dog IslandBlack Island, Kiglapaits-Cutthroat), effort was among the lowest recorded during the past four years (1991-94), especially in 1994 for the Kiglapaits-Cutthroat area. The limited distribution of effort and subsequent interpretation of catch-rate trends must be viewed with caution in that low effort directed towards Atlantic salmon may be insufficient to reflect true abundance patterns in recent years.

Atlantic salmon caught at Nain are for the most part not from 'local' area rivers. Most of the salmon are believed to originate from rivers in central and southern Labrador with some contributions from Newfoundland, the Maritime Provinces, and Quebec (Reddin and Dempson 1986). The overall catch rate data are assumed to reflect a generalized pattern of salmon abundance along the Labrador coast. Catch rate variation among the Nain subareas likely reflects varying patterns of movement of salmon as they migrate past local headlands and outer islands.

## RECRUITMENT OVERFISHING, LABRADOR STOCKS

For SFA 1, estimated numbers of large salmon (2SW) spawners were always less than numbers of parents, i.e., were below the replacement (diagonal) line (Fig. 6). Numbers of spawners were well below target requirement in all years. Except for 1993 and 1994, numbers of spawners in

SFA 2 were also below the replacement line (Fig. 7) and substantially below target requirement for all years.

## RECREATIONAL FISHERY AND COUNTS AT COUNTING FACILITIES

Recreational catches of grilse and large salmon, effort, and catch per unit of effort (CPUE) for Labrador (SFAs 1, 2, and 14B combined), insular Newfoundland (SFAs 3-14A combined), and insular Newfoundland and Labrador combined, 1974-94, are presented in Appendix 2a-c. Data for insular Newfoundland were also rolled into three subdivisions, Northern Peninsula and Eastern (SFAs 14A and 3-8), South (SFAs 9-11), and Southwest (SFAs 12-13) and are shown in Appendix 2d-f. Data for each individual SFA are shown in Appendix 2g-u. Catches for all years prior to 1992 represent retained fish for the entire angling season, when there was no mandatory release of small salmon. Total catches (sum of retained and released fish), effort and catch per unit of effort (CPUE) for individual SFAs and the various combinations of SFAs for the moratorium years 1992-94 and the 1984-89 and 1986-91 means, are presented in Table 8. For insular Newfoundland, except for Southwest (SFAs 12-13), numbers of large salmon released were not included in CPUE for years prior to 1992. For 1992, there was no estimate of released fish and associated effort during the period of retention of catch and hence direct comparisons with 1993 and 1994 should be viewed with caution. In Table 9, catch (retained plus released fish), effort, and CPUE for 1994 are expressed as percentage change in relation to 1992, 1993, and the means for 1984-89 and 1986-91. For insular Newfoundland, Northern Peninsula and Eastern, South, and individual SFAs 3-11, 1987 was not included in the means because in that year drought conditions resulted in the closure of most rivers to angling for the greater part of the season.

Retained catches for 1992-94 and the 1984-89 and 1986-91 means for each SFA and combinations of SFAs are shown in Table 10. Percentage change in retained catch in 1994 in relation to 1992, 1993, and the means, is presented in Table 11. As above, data for 1987 were not included in the means for the areas indicated.

## Labrador (SFAs 1, 2, and 14B combined)

The total catch of small salmon (retained plus released fish) in 1994 (Table 8 and Fig. 8) increased over 1992, 1993 and the 1984-89 and 1986-91 means (just within the $95 \%$ confidence interval (CI) of each mean) (Table 9). The catch of large salmon was similar to 1992, and increased over 1993 and the means (exceeded the upper $95 \%$ confidence limit (CL) of each mean). Effort in 1994 increased over 1992 and 1993 and both means (exceeded the upper CL of each mean). CPUE in 1994 increased over 1992, 1993 and both means (within the CI of each mean).

The number of small salmon retained in 1994 (Table 10 and Fig. 8) was similar to that of 1992 and 1993 but was below the lower CL of each mean (Table 11 and Fig. 9). The retained catch of large salmon increased over 1993, decreased from 1992 and the 1984-89 mean (within the CI of each mean), and was similar to the 1986-91 mean. It should be pointed out that in 1993 the quota for retained fish was not caught in any of the SFAs of Labrador.

SFA 1: The total catch of small salmon in 1994 increased over 1992, 1993 and both means (within the CI each mean). Total catch of large salmon decreased from 1992 but increased over 1993 and the 1984-89 (within the CI of each mean) and 1986-91 (exceeded the upper CL) means. Effort increased over 1992 and 1993 but was below the means (within the CI of each mean). CPUE increased over 1992 and both means (exceeded the upper CL of each mean).

The number of small salmon retained in 1994 increased over 1992 and 1993 but declined from the 1984-89 (below the lower CL) and 1986-91 (within the CI) means. The number of large salmon retained increased over 1993 but decreased from 1992 and the 1984-89 (below the lower CL) and 1986-91 (within the CI) means.

SFA 2: The total catch of small salmon in 1994 increased over 1992, 1993 and both means (exceeded the upper CL of each mean). A similar pattern was followed by large salmon. Effort was similar to 1993 but exceeded 1992 and the upper CL of each mean. CPUE increased over 1992, 1993, and both means (above the upper CL of each mean).

The number of small salmon retained in 1994 was similar to 1992, increased over 1993, but was below the means (within the CI of each mean). The retained catch of large salmon increased over 1992, 1993, and the means (within the CI).

A counting fence was operated in Sandhill River in 1994 for the first time since 1973. The count of small salmon in 1994 (Table 12) was slightly higher than that for 1972 which was the lowest for the period 1970-73. The count of large salmon (Table 13) was substantially higher than any recorded in 1970-73. The proportion of large salmon in 1994 was 0.263 which compares to an average of 0.073 for 1970-73.

SFA 14B: The total catch of small salmon in 1994 decreased from 1992, 1993, and both means (below the lower CL of each mean). The same applied to the catch of large salmon, except the decline from each mean was within the limits of the CI. Effort increased over 1992, 1993, and both means (above the upper CL of each mean) while CPUE was the opposite.

The retained catch of small salmon in 1994 decreased from 1992, 1993, and both means (below the lower CL); the same trend was true for large salmon but the decline was within the $95 \%$ CI of both means.

Counting fences were operated in Forteau River and L'Anse-au-Loup River for the first time in 1994. Counts of small and large salmon are provided in Tables 11 and 12, respectively.

## Insular Newfoundland (SFAs 3-14A combined)

The total catch of small salmon in 1994 (Table 8 and Fig. 10) decreased from 1993 but increased over 1992 and both means (within the CI of each mean) (Table 9). Effort increased over

1992, 1993, and both means (above the upper CL of each mean). CPUE decreased from 1992, 1993, and the 1984-89 mean (within the CI) and was similar to the 1986-91 mean.

The number of small salmon retained in 1994 (Table 10 and Fig. 10) increased over 1992 and 1993, decreased from the 1984-89 mean (within the CI), and was similar to the 1986-91 mean (Table 11 and Fig. 11).

## Northern Peninsula and Eastern (SFAs 14A, 3-8 combined)

The total catch of small salmon in 1994 (Table 8 and Fig. 12) was similar to 1993 and increased over 1992 and both means (exceeded the upper CL of each mean) (Table 9). Effort increased over 1992, 1993, and the upper CL of each mean. CPUE decreased from 1993 but was similar to 1992 and the means.

The 1994 retained catch of small salmon (Table 10 and Fig. 12) increased over 1992, 1993, and both means (within the CI of each mean) (Table 11 and Fig. 11).

SFA 14A: The total catch of small salmon in 1994 decreased slightly from 1993, was similar to 1992 , and increased over both means (within the CI of each mean). The number of large salmon released in 1994 increased over 1992, 1993, and the upper CL of each mean. Effort increased over 1992, 1993, and both means (exceeded the upper CL of each mean). CPUE decreased from 1992 and 1993 but was similar to both means.

The number of small salmon retained in 1994 increased over 1993 and was similar to that of 1992 and the means.

Neither of the three individual river quotas was reached in 1994. Quotas and catches for each river were as folows:

| River | Quota | 1994 | 1993 | 1992 | 1991 | 1990 | 1989 |
| :--- | :---: | ---: | ---: | ---: | ---: | ---: | ---: |
| Lomond R. | 350 | 325 | 281 | $357^{*}$ | 328 | $386^{*}$ | 270 |
| Watson's Bk. | 50 | 30 | 20 | $49^{*}$ | 6 | 36 | 6 |
| Pincent's Bk. | 10 | 2 | 2 | 0 | 3 | $10^{*}$ | 6 |

*Quota reached.
Adult salmon counting facilities are located in Lomond River, Torrent River, and Western Arm Brook. The count of small salmon at the Lomond River fishway in 1994 increased over 1992, 1993, and both means (exceeded the upper CL of each mean) (Table 12 and Fig. 13). The count of large salmon decreased from 1992, increased over 1993, and increased over the means (above the upper CL) (Table 13 and Fig. 14). The count of small salmon at the Torrent River fishway in 1994
decreased from 1993 but increased over 1992 and the means (exceeded the upper CL) (Table 12 and Fig. 13). The count of large salmon increased over 1992 and 1993 and exceeded the upper CL of each mean (Table 13 and Fig. 14). At the counting fence in Western Arm Brook, the count of small salmon in 1994 was similar to that of 1993 and increased over 1992 and the upper CL of each mean (Table 12 and Fig. 13). The count of large salmon increased over 1992 and 1993 and exceeded the upper CL of each mean (Table 13 and Fig. 14). The proportion of large salmon for Lomond River in 1994 was similar to 1993 and the means but below 1992; for Torrent River and Western Arm Brook, the proportion of large salmon in 1994 was higher than for 1992, 1993, and the means (Table 14 and Fig. 15).

SFA 3: Total catch of small salmon and effort in 1994 increased over 1992 and 1993 means and exceeded the upper CL of each mean. CPUE decreased from 1993 but increased over 1992 and the means (exceeded the upper CL).

The number of small salmon retained in 1994 increased over 1992, 1993, and the upper CL of each mean.

SFA 4: The total catch of small salmon in 1994 decreased slightly from 1993 but increased over 1992 and the 1984-89 (within the CI) and 1986-91 (similar to the upper CL) means. Effort increased over 1992, 1993, and the upper CL of each mean. CPUE decreased from 1992, 1993, and the 1984-89 mean (within the CI) and was similar to the mean for 1986-91.

Counts of small (Table 12 and Fig. 16) and large salmon (Table 13 and Fig. 17) are available for fishways located in the Exploits River (Bishop's Falls and Great Rattling Brook) and Salmon Brook (Gander River) and counting fences in Gander River and Campbellton River. Data are available for Campbellton River for 1993 and 1994. The count of small salmon for Campbellton River in 1994 decreased from 1993 while the opposite applied to large salmon. At Bishop's Falls, the count of small salmon in 1994 decreased from 1993 but increased over 1992 and the upper CL of each mean. The count of large salmon increased over 1992, 1993, and the upper CL of each mean. At Great Rattling Brook, the count of small salmon in 1994 decreased from 1992, 1993, and the 1984-89 mean (within the CI) and increased over the 1986-91 mean (within the CI). The count of large salmon increased over 1992, 1993 and the upper CL of each mean. The count of small salmon at the Gander River counting fence decreased from 1993, was similar to 1992, and increased over the upper CL of the mean. The count of large salmon decreased from 1992 and 1993 but remained above the upper CL of the mean. The count of small salmon at Salmon Brook in 1994 decreased from 1992, 1993, and the 1984-89 mean (within the CI), and increased over the 1986-91 mean (within the CI). The count of large salmon was similar to 1993, decreased from 1992, and increased over the upper CL of each mean. The proportion of large salmon for Bishop's Falls and Great Rattling Brook in 1994 increased over 1992, 1993, and the means (Table 14 and Fig. 18). The proportion for Salmon Brook was similar to 1992 but increased over 1993 and the means. At the Gander River counting fence, the proportion of large salmon in 1994 decreased from 1992 and was slightly less than than for 1993 and the mean.

SFA 5: The total catch of small salmon in 1994 was similar to 1993 and increased over 1992 and the means (within the CI). Effort increased over 1992, 1993, and the upper CI of each mean while the reverse was true for CPUE.

The number of small salmon retained increased over 1992, 1993, and the 1986-91 mean (within the CI) and was similar to the 1984-89 mean.

Counts of grilse (Table 12 and Fig. 19) and large salmon (Table 13 and Fig. 20 ) are available from fishways in Middle Brook and Terra Nova River (upper and lower). The count of small salmon at Middle Brook in 1994 decreased from 1993 but increased over 1992 and the upper CL of each mean. The count of large salmon was similar to 1993 and increased over 1992 and the upper CL of each mean. At the lower Terra Nova River fishway, the count of small salmon in 1994 decreased from 1993 and increased over 1992 and the means (within the CI of the 1984-89 mean but exceeded the upper CL of the 1986-91 mean). The count of large salmon decreased from 1992 and 1993 but remained above the upper CL of each mean. The counts of small and large salmon for the lower Terra Nova River in 1993 were incomplete due to fish bypassing the fishway. This was due to the washout of the diversion dam above the fishway and unusually high water levels. At the upper Terra Nova River fishway, the count of small salmon in 1994 increased over 1992, 1993, and the upper CL of each mean. The count of large salmon was similar to 1993, decreased from 1992, but exceeded the upper CL of each mean. The proportion of large salmon for Middle Brook in 1994 increased over 1992, 1993, and the means (Table 14 and Fig. 21). The proportion for both Terra Nova River fishways decreased from 1992 and 1993 but was above the means.

SFA 6: The total catch of small salmon in 1994 increased over 1992 but decreased from 1993 and the means (within the CI). Effort and CPUE displayed a similar pattern

The number of small salmon retained in 1994 was similar to 1992 and decreased from 1993 and the 1984-89 (below the lower CL) and 1986-91 (within the CI) means.

SFA 7: Total catch of small salmon in 1994 increased over 1992 and 1993 but decreased from the 1984-89 (below the lower CL) and 1986-91 (within the CI) means. Effort was similar to 1993, decreased from 1992 and the 1984-89 mean (within the CI), and increased over the 1986-91 mean (within the CI). CPUE increased over 1992 and 1993 but decreased from the means (within the CI ).

The retained catch of small salmon in 1994 increased over 1992 and 1993 but decreased from the 1984-89 (below the lower CL) and 1986-91 (within the CI) means.

SFA 8: The total catch of small salmon in 1994 was similar to 1993 but decreased from the 1984-89 mean (below the lower CL) and the 1986-91 mean (within the CI). Effort decreased from 1993 and the 1984-89 (below the lower CL) and 1986-91 mean (within the CI) means. CPUE increased over 1993 and the means (within the CI).

The number of small salmon retained in 1994 increased slightly over 1993 but decreased from the 1984-89 (below the lower CL) and 1986-91 (within the CI) means.

## South (SFAs 9-11)

The total catch of small salmon in 1994 (Table 8 and Fig. 22) was similar to 1992 but decreased from 1993 and the 1984-89 (below the lower CL) and 1986-91 (within the CI) means (Table 9). Effort decreased from 1993 and the 1984-89 mean (within the CI), was similar to the 1986-91 mean, and increased over 1992. CPUE decreased from 1992, 1993, and the 1984-89 (below the lower CL) and 1986-91 (within the CI) means.

The retained catch of small salmon in 1994 (Table 10 and Fig. 22) increased over 1992 but decreased from 1993 and the 1984-89 (below the lower CL) and 1986-91 (within the CI) means (Table 11 and Fig. 11).

SFA 9: The total catch of small salmon in 1994 was similar to 1992 but decreased from 1993 and the 1984-89 (below the lower CL) and 1986-91 (within the CI) means. Effort increased over 1992, was similar to the 1986-91 mean, and decreased from 1993 and the 1984-89 mean (within the CI). CPUE decreased from 1992, 1993, and the 1984-89 (below the lower CL) and 1986-91 (within the CI ) means.

The number of small salmon retained in 1994 increased over 1992 but decreased from 1993 and the 1984-89 (below the lower CL) and 1986-91 (within the CI) means. In 1993, the retention period for small salmon in this SFA lasted the entire season (i.e., the quota was not caught.

Counts of small salmon (Table 12 and Fig. 23) and large salmon (Table 12 and Fig. 24) were provided by counting fences (Biscay Bay River and Northeast Brook, Trepassey) and a fishway (Rocky River). The count of small salmon for Biscay Bay River in 1994 increased over 1992, 1993, and the 1986-91 mean (within the CI) but decreased from the 1984-89 mean (within the CI). The count of large salmon increased over 1992 but decreased from 1993 and the means (within the CI). The number of small salmon entering Northeast Brook, Trepassey in 1994 increased over 1992 and 1993 and was similar to the means. The count of large salmon increased over 1992 but declined from 1993 and the 1984-89 (below the lower CL) and 1986-91 (within the CI) means. The count of small salmon for Rocky River in 1994 decreased from 1992, 1993, and the means (within the CI). The count of large salmon decreased from 1992 and 1993 but increased over the 1984-89 (above the upper CL) and 1986-91 (within the Cl) means. The proportion of large salmon for Biscay Bay River in 1994 (Table 14 and Fig. 25) decreased from 1993 and was comparable to 1992 and the means. The proportion for Northeast Brook, Trepassey was the lowest on record. The proportion for Rocky River decreased from 1992 and 1993 but was above the means.

SFA 10: The total catch of small salmon in 1994 decreased from 1993 and the 1984-89 mean (within the CI) and increased over 1992 and the 1986-91 mean (within the CI). Effort decreased
from 1993 but increased over 1992 and the 1984-89 (within the CI) and 1986-91 (above the upper CL) means. CPUE decreased from 1992, 1993, and the 1984-89 (below the lower CI) and 1986-91 (within the CI) means.

The number of small salmon retained in 1994 increased over 1992 and 1993, was similar to the 1986-91 mean, but decreased from the 1984-89 mean (below the lower CL).

The count of small salmon (Table 12 and Fig. 26) at the Fishway in Northeast River (Placentia) in 1994 decreased from 1992 and 1993 but increased over the means (within the CI). The count of large salmon (Table 13 and Fig. 27) increased over 1992, 1993, and the means (above the upper CL). The proportion of large salmon for Northeast River in 1994 increased over 1992, 1993, and the means (Table 14 and Fig. 28).

SFA 11: Total catch of small salmon decreased from 1992, 1993, and the 1984-89 (below the lower CL) and 1986-91 (within the CI) means. Effort was similar to 1993, increased over 1992, but decreased from the 1984-89 (below the lower CL) and 1986-91 (within the CI) means. CPUE decreased from 1992, 1993, and the means (within the CI of each mean).

The number of small salmon retained in 1994 was similar to 1992 but decreased from 1993 and the 1984-89 (below the lower CL) and 1986-91 (within the CI) means.

The count of small salmon (Table 12 and Fig. 29) at the Conne River counting fence was below 1992, 1993, and the lower CL of each mean. The count of large salmon (Table 13 and Fig. 30) was similar to 1993 but below 1992 and the lower CL of each mean. The proportion of large salmon for Conne River in 1994 decreased from 1992 but increased over 1993 and the means (Table 14 and Fig. 31).

## Southwest (SFAs 12-13)

The total catch of small salmon in 1994 (Table 8 and Fig. 32) decreased from 1992, 1993, and the means (within the CI of each mean) (Table 9). The number of large salmon released was similar to 1992 but increased over 1993 and the means (above the upper CL of each mean). Effort decreased from 1992, 1993, and the means (within the CI of each mean). CPUE followed a similar pattern to effort although the magnitude of differences was less.

The number of small salmon retained in 1994 (Table 10 and Fig. 32) decreased from 1992, 1993, and the means (below the lower CL of each mean) (Table 11 and Fig. 11).

SFA 12: The total catch of small salmon in 1994 decreased from 1992, 1993, and the means (within the CI of each mean). The number of large salmon released decreased from 1992 but increased over 1993 and the means (within the CI of the 1984-89 mean but above the upper CL of the 1986-91 mean). Effort was similar to 1992 and the 1986-91 mean and decreased from 1993 and
the 1984-89 mean (within the CI). CPUE was the same as in 1993 but decreased from 1992 and the means (within the CI of each mean).

The number of small salmon retained in 1994 decreased from 1992, 1993, and the means (below the lower CL of the 1984-89 mean but within the CI of the 1986-91 mean).

SFA 13: The total catch of small salmon for 1994 decreased from 1992, 1993, and the means (within the CI of each mean). The number of large salmon released was similar to 1992 and increased over 1993 and the upper CL of the means. Effort and CPUE decreased slightly from 1992, 1993, and the means (within the CI of each mean).

The retained catch of small salmon decreased from 1992, 1993 and the lower CL of each mean. The quota for retained small salmon was not caught in 1993.

The only river quotas reached in 1994 were for Fischell's River and Fox Island River. Individual river quotas and catches for SFA 13, 1989-94, were as follows:

| River | Quota | 1994 | 1993 | 1992 | 1991 | 1990 | 1989 |
| :--- | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Barachois R. | 175 | 154 | $230^{*}$ | $263^{*}$ | 68 | 138 | 79 |
| Fischell's Bk. | 200 | $216^{*}$ | 157 | 133 | 157 | 116 | 17 |
| Flat Bay R. | 250 | 128 | 173 | 211 | $251^{*}$ | $277^{*}$ | 130 |
| Harry's R. | 350 | 153 | 319 | 311 | $370^{*}$ | $706^{*}$ | 324 |
| Fox Island R. | 50 | $55^{*}$ | $52^{*}$ | $52^{*}$ | $56^{*}$ | $91^{*}$ | 38 |
| Serpentine R. | 150 | 116 | $150^{*}$ | $176^{*}$ | 132 | 131 | 107 |

*Quota reached.
A counting fence was operated in Highlands River in 1992 and 1993; prior to this, counts were available for 1980-82. The count of small salmon (Table 12) in 1994 was similar to 1993 and higher than any for the period 1980-82. The count of large salmon (Table 13) increased over 1993 and was substantially higher than than any recorded in 1980-82. The proportion of large salmon for 1994 was 0.505 which compares to 0.363 for 1993 and 0.312 for the period 1980-82.

Counts of small (Table 12 and Fig. 33) and large (Table 13 and Fig. 34) salmon were also available for Humber River and Pinchgut Brook. The estimated return of small salmon for Humber River in 1994 determined through a mark-recapture study (Mullins et al. MS 1995), decreased from 1992 and 1993 and the pre-moratorium year 1990, but increased over 1991. The count of large salmon in 1994 decreased from 1993 but increased over all other years. The counts of small and large salmon for Pinchgut Brook in 1994 were similar to 1993 but increased over 1992. The proportion
of large salmon for Humber River in 1994 decreased from 1992 but increased over remaining years (Fig. 35). The proportion for Pinchgut Brook increased over 1992 and 1993.

## COUNTS AT COUNTING FACILITIES - AN OVERALL SUMMARY

Results of the nonparametric ratio test (Table 15) suggest the probability of the observed ratio of 1.77 for returns of small salmon is about 0.0085 . This implies that, collectively over all rivers, there was a significant increase in small salmon returns during the moratorium years 1992-94 compared to the pre-moratorium period 1986-91. A separate analysis of Northern Peninsula and Eastem rivers (Torrent River, Western Arm Brook, Exploits River, Gander River, Middle Brook, and Terra Nova River) gave a similar result ( $\mathrm{P}=0.0000$ ). For South division rivers (Biscay Bay River, Northeast Brook (Trepassey), Northeast River (Placentia), and Conne River), there was no significant improvement in returns of small salmon for moratorium years over pre-moratorium years ( $\mathrm{P}=$ 0.9685 ). Returns of large salmon for all rivers collectively also increased significantly during the three moratorium years $(\mathbf{P}=0.0120)$ as did those of Northern Peninsula and Eastern rivers $(\mathbf{P}=0.0000)$ (Table 15). The result for South rivers was not significant $(P=0.9225)$. Some of the strongest declines in returns of small and large salmon in recent years for South rivers occurred in Conne River. If the count of large salmon for Conne River is omitted from the analysis, a significant result is obtained ( $\mathrm{P}=0.0165$ ). Omitting Conne River small salmon, however, still produces a non-significant result $(\mathrm{P}=0.3195)$.

The results of comparisons of mean counts of small and large salmon for the same moratorium and pre-moratorium periods on an individual river basis are shown in Table 16. The outcome was similar to that of the separate collective analysis for Northern Peninsula and Eastern and South divisions presented above. It shoud be noted that except for small and large salmon for Northeast River (Placentia) and large salmon for Rocky River, the direction of change was negative.

## EFFECTS OF BAG LIMIT SPLIT ON DISTRIBUTION OF CATCH AND EFFORT

During consultations with the general public, an opinion was expressed that the split in the season bag limit of three fish prior to and after July 31, was in effect, a season limit of three fish. Anglers contended that historically considerably less effort was expended after July 31 than prior to that date. Table 17 shows this to be the case. A related opinion was that the split would result in an increase in effort after July 31 in an attempt by anglers to retain the remaining three fish. In SFAs 3 and 4, the proportion effort expended after July 31 in 1994 increased over the mean for 1984-91 (it surpassed the maximum for SFA 3 and was similar to the maximum for SFA 4), while for SFA 5, there was little change from the mean (Table 17). For SFAs 6-10, there were substantial increases in proportion of effort after July 31 in 1994 compared to the means, but it must be remembered that rivers in these areas were closed for most of July due to high water temperatures and low water levels. There was a substantial increase in proportion of effort (exceeded the mean and maximum) after July 31 in SFA 11. For SFAs 12-14A, there were increases over the means but they were within the range observed for 1984-91. Traditionally, salmon are not known to enter rivers in these SFAs later in the season. Also rivers in SFA 13 were open only to hook-and-release fishing after August
8. It appears therefore that there was a redistribution of effort into the post-July 31 period for SFAs 3,4 , and 11 .

The redistribution of effort for SFA 4 did not translate into an increase in proportion of catch while for SFA 11 it did. The increased proportions of catch for SFAs 6-10 after July 31 reflect the river closures in July.

## SMOLT-TO-ADULT SURVIVAL

Smolt-to-adult survival of $5.4 \%$ for 1994 (adult year) for Northeast Brook (Trepassey) (SFA 9) increased over 1993 and was the highest since 1988 (Table 18). That of Conne River (SFA 10) was the lowest recorded to date (2.7\%). A study by Dempson and O'Connell (MS 1994) showed a positive relationship between an index of smolt condition and sea survival for smolts leaving both Conne River and Northeast Brook. Based on condition of smolts in 1993, survival to adults in 1994 was predicted to be $5.25 \pm 1.23 \%$ for Northeast Brook and $6.68 \pm 1.61 \%$ for Conne River. Various factors that may have contributed to low returns for Conne River are discussed separately (Dempson and Reddin MS 1995). Those factors that were associated with decreased returns included decreased condition of smolts, possible losses due to legal and illegal interceptory fisheries, and changes in available marine habitat.

Smolt-to-adult survival for Campbellton River (SFA 4) in 1994 was $9.05 \%$ (Appendix 3). Results of a tagging study indicated that $23.8 \%$ of the small salmon returning to Campbellton River were previous spawners which were excluded from the survival calculations. The corrected survival rate after removal of previous spawners was $7.0 \%$.

The number of small salmon returning to the Western Arm Brook counting fence in 1994 was anticipated to be $13 \%$ below the 1993 count based on a $13 \%$ decrease in the smolt count from 1992 to 1993 . The actual return in 1994 was $7.4 \%$ above the 1993 returns as a result of the $16 \%$ increase in sea-survival of smolts compared to 1993 (Table 18). The 1994 smolt count was $31 \%$ below the count in 1993. Assuming that sea-survival in 1995 will be similar to 1994 (7.1\%), returns of small salmon to the river in 1995 are anticipated to be 31\% below returns in 1994.

## COMMENTS AND CONCLUSIONS

The 1984-89 mean used above for comparisons corresponds to years under major management changes in the commercial fishery in the Newfoundland Region (O'Connell et al. MS 1992a). In 1990 and 1991, the commercial fishery in both insular Newfoundland and Labrador was controlled by a quota in each SFA (O'Connell et al. MS 1992b). The mix of management measures in effect during 1984-89 on the one hand and the imposition of commercial quotas in 1990 and 1991 on the other, should be kept in mind when making evaluations based on the 1986-91 mean. In 1992, in addition to the closure of the commercial Atlantic salmon fishery, a moratorium on the Northern Cod Fishery was implemented in early July which should have resulted in the elimination by-catch in
cod fishing gear in SFAs 1-9. The cod moratorium continued in 1994. In August 1993, a moratorium was placed on cod fishing in SFAs 11-14A which remained in effect in 1994. In spite of these moratoria, in 1993 field crews noted that net-marked Atlantic salmon were showing up at counting facilities. In 1994, an attempt was made to quantify the incidence of net-marked fish in Gander (O'Connell et al. MS 1995a), Campbellton (O'Connell et al. MS 1995b), and Conne (Dempson et al. MS 1995) rivers. Of the fish examined at counting fences in these rivers, the incidence of net scarring observed was $16.1,6.2$, and $18.6 \%$, respectively.

Recent management changes in the recreational fishery, specifically the implementation and changing of quotas in SFAs along with mandatory hook-and-release fishing, and changing daily and seasonal bag limits, has seriously compromised the usefulness of angling data in terms of comparability with the past, especially when used as indices of abundance. Adding hook-and-release fish to retained fish, and comparing this total to retained fish for years prior to 1992, assumes the amount of effort expended applies equally to hook-and-release and retained fish. Reports from user groups suggest less effort was directed towards hook-and-release fishing. In the interpretation of trends and drawing of conclusions with respect to abundance, most weight is placed on information obtained from counting facilities than from recreational fishery data. In Labrador, recreational catches have historically constituted only a small proportion of the total catches (recreational plus commercial) and therefore a cautious approach must be taken in the interpretation of trends as representative of abundance.

## Labrador

Although the commercial fishery quota for all of Labrador was caught in 1994, this quota was considerably diminished from previous years. Since the overall commercial quota was not caught in years prior to 1994, data for these years (1990-93) can be used as indices of abundance, although the decreases in licensed effort could have resulted in somewhat lower catches. In 1994, the quota was exceeded slightly in SFA 2 but not attained in SFAs 1 and 14B. In 1992-94, it is possible that fish once taken in the commercial fishery in SFA 3 and to a lesser extent in SFAs 4-7, contributed to catches in Labrador. In the past Labrador-origin Atlantic salmon have been intercepted in these areas. In spite of this and the recent reductions in the commercial fishery, compared to 1992-94, river escapements of small and large salmon for Labrador as a whole, as indicated by commercial and recreational fishery data, have been as high or higher in the past. This and an analysis of trends in estimated total population sizes of small and large salmon for Sandhill River (Reddin et al. MS 1995), suggest that population sizes of small and large salmon have declined overall in Labrador in recent years. This conclusion is corroborated by the relationships of parents to future spawners, catch rates at Nain, and trends in catches of small and large salmon in Labrador and small salmon with a sea age greater than three years at West Greenland. Low population sizes of small and large salmon in 1994 correspond to years of above average commercial and recreational fishery catches in 1987 and 1988. Recreational catches and catch rates in 1990 and 1991 might be indicative of below average spawning escapements, which could contribute to lower future returns relative to 1994, should natural survival rates remain the same. It should be pointed out that low catches in 1991 could have been due in part
to a delay in the entry of fish into rivers as a result of severe sea-ice conditions throughout much of the summer.

Even though there appears to have been some inprovement in returns in the past few years, the present low population sizes of small and large salmon compared to the late 1970 s and early 1980s, years when there was a substantial commercial fishery, is a matter of serious concern. The marked decline in recreational catches of small and large salmon in SFA 14B in 1994, and the fact that the commercial quota for this area was not caught, is of particular concern. Consequently, exploitation of Labrador stocks and in particular the large salmon component, which contributes substantially to egg deposition, should be as low as possible.

## Insular Newfoundland

As a result of the closure of many rivers in SFAs 6-10 during the height of the angling season, comparison of angling data for 1994 for all of insular Newfoundland (SFAs 3-14A combined) and for South (SFAs 9-11) with past years, is not appropriate. Since the contribution to Northern Peninsula and Eastern (SFAs 14A, 3-8) total catch by SFAs 6-8 has been relatively small, it is valid to make historical comparisons for rivers in this area. Total catches (retained plus released fish) and CPUE in moratorium years 1992-94 for Northern Peninsula and Eastern rivers were comparable to or lower than levels observed in some pre-salmon moratorium years. Also, at several counting facilities (including Gander River as evidenced by Salmon Brook), although counts of small salmon in 1992-94 were significantly above the 1986-91 mean, counts similar to or greater than those of 1992-94 have occurred in certain pre-salmon moratorium years.

Returns of small salmon to counting facilities for South (SFAs 9-11) in 1992-94 were low relative to pre-salmon moratorium years. While smolt-to-adult survival back to the river for Northeast Brook, Trepassey (SFA 9) improved in 1994, it was still as low as when there was a commercial fishery. The situation for Conne River worsened. This is suggestive of high or above average natural mortality at sea in 1992-94 for these rivers and probably for southern Newfoundland rivers in general. Since 1987, smolt production for Conne River and Northeast Brook (except for 1994) was relatively stable. Conne River, in contrast to the other rivers under consideration, is characterized by early runs of grilse (since 1986, $70-80 \%$ of the run has been complete by early July). The implementation of the 1984 management plan, which delayed the opening of the commercial fishery from mid-May to June 5, should have had a more noticeable impact on Conne River returns than the moratorium.

Catches of small salmon for Southwest (SFAs 12-13) during moratorium years were well below those recorded for several pre-moratorium years. Low returns to rivers in SFA 13 (St. George's Bay) resulted in closures to angling after August 8. Approximately 10\% of total season retained catch of small salmon was historically taken after this closure date, which must be kept in mind when comparing 1994 with previous years. Counts of small salmon for Humber River in 1992 and 1993 increased over the two pre-moratorium years but not in 1994. Reasons for the lack of improvement in returns of small salmon to SFAs 12 and 13 during the commercial salmon fishery
moratorium are unclear. Opinions expressed during public consultations were that clear-cutting of forest areas along several rivers in St. George's Bay and poaching may have played a significant role. Stocks in SFAs 12 and 13 were not expected to benefit as much from the moratorium as other areas of insular Newfoundland because these stocks were subjected to a shorter commercial fishery season in 1978, which should have resulted in lower exploitation. Typically, Atlantic salmon enter rivers in SFAs 12 and 13 in late May and early June. The change in the commercial fishing season opening date from May 18 to June 5 in 1984 in other areas of insular Newfoundland should have reduced the interception of fish destined for SFAs 12 and 13. Also, the closure of the SFA 12 commercial fishery in 1984 should have further reduced exploitation on these stocks. Consequently, the number of fish available for release into freshwater during the moratorium years would be lower than for some other areas.

Levels of recreational catch and returns to counting facilities, in the absence of commercial fisheries, suggest the overall total population sizes of small salmon for insular Newfoundland in 199294 were low relative to pre-salmon moratorium years. An analysis of trends in estimated total population sizes of small salmon for Gander River (O'Connell et al. MS 1995a), Middle Brook and Biscay Bay River (O'Connell et al. MS 1995b), Conne River (Dempson et al. MS 1995), and Humber River (Mullins and Reddin MS 1995) for the period 1974-94, supports this conclusion. Angling data and counts of small salmon at several counting facilities indicate that in general spawning escapements were low during 1989-91. This suggests that returns to Northern Peninsula and Eastern rivers in 1995-96 could be lower than in 1992-94 and returns to South and Southwest rivers could continue at the low levels indicative of the past few years, if natural survival rates remain the same. It should be noted that, although returns to some rivers have increased since the commercial fishery moratorium, no new adults have yet been produced. Eggs laid in 1992 will not return as adults until at least 1997 and even later in more northern areas. It should be kept in mind that a single season of extreme low water levels could negatively influence survival of juvenile fish. For example, the low water levels in western Newfoundland in 1989 may have had a negative impact on adult salmon returns in 1994 similar to low water conditions in 1987 in other parts of the island.

An objective of the split in the recreational fishery bag limit (three fish before and after July 31) was to constrain overall retained catch to a level similar to that achieved by quotas in 1992 and 1993. The total number of small salmon retained for all of insular Newfoundland in 1994 was 28949 which compares to 23127 in 1992 and 24693 in 1993. The 1994 catch, however, is without the usual contribution of rivers in SFAs 6-10 which were closed to angling during most of July. The number of small salmon retained in Northern Peninsula and Eastern rivers in 1994 increased by approximately $50 \%$ over 1992 and 1993. It appears that the 1994 Management Plan did not achieve its objective on limiting exploitation to 1992 and 1993 levels and spawning escapements decreased accordingly.

Effort expenditure in 1994 for insular Newfoundland as a whole was the highest on record. This was driven by the increase in Northern Peninsula and Eastern rivers since the remaining divisions showed declines. Some of this increase might have been redirected from areas with closures in July.

While returns of large salmon showed an overall improvement in 1992-94 compared to the 1986-91 mean, for several Northern Peninsula and Eastern and South counting facilities, there were pre-salmon moratorium years when returns were higher. Numbers of large salmon released in SFAs 12,13 , and 14A during the moratorium years showed a marked increase over the means overall but there were comparable catches in the late 1970s and early 1980s. For all Northern and Eastern counting facilities except Lomond River and Gander River, proportions of large salmon in all three years of the moratorium were higher than the 1984-89 and 1986-91 means. This was also the case for three out of five South counting facilities.

In 1994, detailed stock assessments were carried out for nineteen rivers with counting facilities, spread throughout the Newfoundland Region. Target egg deposition requirement was met in eight of these rivers (Appendix 4).

## Acknowledgement

We thank C. E. Bourgeois for providing the counts for Exploits, upper Terra Nova, and Rocky rivers for 1994 and previous years.

## Appendix 1

## THE RESULTS OF

DFO - PUBLIC MEETINGS ON 1994 ATLANTIC SALMON ASSESSMENTS IN NEWFOUNDLAND \& LABRADOR

Purpose: to allow the public to have input into the stock assessment process.
Background: Science Branch augmented 1994 stock assessments by incorporating the knowledge of anglers and fishers through a series of public meetings which provided the opportunity for public input. This process provided fishers the opportunity to review the information available to assess the status of salmon stocks in 1994 and to provide information to biologists on their observations regarding the state of the resource. Each meeting began with a brief presentation by DFO biologists showing information on catch statistics and counts at enumeration facilities in the local area; then the proceedings were opened for public comment and input.

Information from fishers: the questions asked were,

- what were the effects of 1994 water levels and water temperatures on angling success?
- what were your perceptions of abundance of salmon in 1994?
- have angling habits changed with the introduction of hook \& release?
- how did the 1994 management plan affect angling effort and success? and,
- what information do you have on long-term population size?

Public Meeting Locations \& Attendance, 1994:

| LOCATION | DATE | DFO | ANGLERS \& ANGLER <br> REPRESENTATIVES | TOTAL |
| :--- | :---: | :---: | :---: | :---: |
| St. John's | Oct. 17 | 7 | 10 | 17 |
| Gander | Oct. 18 | 4 | 15 | 19 |
| Stephenville | Oct. 18 | 7 | 20 | 27 |
| Phum Point | Oct. 19 | 7 | 22 | 29 |
| Forteau | Oct. 20 | 5 | 13 | 18 |
| Corner Brook | Oct. 24 | 4 | 41 | 45 |

## ST. JOHN'S, OCTOBER 17, 1994

## 1. Effect of 1994 water levels and water temperatures on angling success.

## General

- Overall it was felt that effort was redistributed from Avalon Peninsula rivers to other rivers on the island and in southern Labrador.

Specific

- Low water levels decreased the number of angling spots in a given river and concentrated effort.
- Salmonier River, Branch River, and North Harbour River: water levels were low in all three rivers from nearly the start of the angling season to the end.
- Most anglers felt that catchability was lower in 1994 due to low water levels and high temperatures.

## 2. Abundance of salmon in 1994.

## General

- there was low abundance of salmon in southern Labrador in 1994.

## Specific

- Salmonier River, Branch River, and North Harbour River: when Salmonier River reopened for angling towards the latter part of July, it appeared that a lot of salmon moved into the river at that time. The same applied to North Harbour River where salmon were also noted during the extended season for brown trout. Anglers felt that salmon held off from entering Avalon rivers to await favourable water conditions.

3. Changes in angling habits due to hook and release.

## General

- Opinion ranged from "its part of the psyche now" to "it is not popular in Newfoundland and that a released fish will not survive, so you might as well kill it and have done with it".
- Some felt that if done properly, hook and release is effective; however, more education is needed in this regard.
- Most felt that not as much effort was put into hook-and-release fishing as for retention and agreed that this is a confounding factor in historical comparisons involving angling data.
- One person felt that most people prefer retention of salmon and that they will practice hook and release only when they have a pool or section of river to themselves.

## Specific

- Gander River: one person made the observation that it appeared that more people were practicing hook-and-release fishing on this river in 1994.

## 4. Effect of the 1994 management plan on angling effort and success.

- It was the general conclusion that the 3:3 seasonal bag limit tag system (3 fish prior to and 3 fish after July 31) did not result in a rush for fish. Thus, 1994 catch and effort data are not comparable to that of 1992-93 when it is generally felt that angling effort was redirected to the earlier part of the season.
- Anglers expended more effort in August in 1994 than in the past, in an attempt to get the 3 post-July 31 fish.

5. Information on long-term population size in local area.

- No information was forthcoming at this meeting.

6. Other.

- There was considerable interest in the contribution of repeat spawners to spawning escapements since the commercial fishery moratorium and possible causes of low survival of kelts in recent years; also concerns were expressed regarding the general low smolt-adultsurvival experienced during commercial salmon fishery moratorium years.

## GANDER, OCTOBER 17, 1994

1. Effect of 1994 water levels and water temperatures on angling success.

- Exploits River: this is a regulated watershed and water levels do not fluctuate to the same extent as on unregulated rivers.
- Gander River: the effects of low water levels are not felt in the lower reaches of Gander River to the same extent as other rivers because of its size and the presence of four large ponds on the main stem; also, Gander Lake water influences water temperatures in the upper reaches of the main stem.
- Campbelton River: there was poor angling success due to low water levels and high water temperatures.
- Grey River: one person reported fishing to be very good the first few days of the season but this ended when water levels rose substantially and remained high for the next eight days or so.
- Humber River: there was a report that fishing for large salmon was very good in August when water levels were high and temperatures cooler.

## 2. Abundance of salmon in 1994.

## General

- Some people felt that abundance in 1994 was down overall from 1993.

## Specific

- Gander River: catch rates for Gander River in 1994 were lower than in 1993 in their opinion. There was good fishing in the Northwest Gander River in August.
- Exploits River: it was noted that returns to the Middle Exploits increased in 1994 while returns to Great Rattling Brook decreased, and the distinction was made that the Middle Exploits is an enhanced stock while Great Rattling is a natural stock.
- Grand Codroy River: one person reported that fishing in this river was very poor in 1994.
- Eagle River: fishing in this river was very good in 1994, especially for large salmon.

## 3. Changes in angling habits due to hook and release.

## General

- It was felt that it could take a decade to get hook and release entrenched in Newfoundland and Labrador, especially for young people just entering the fishery.
- The length of time a fish is played is more important than whether a barbed or barbless hook is used.
- The major concern with hook and release is mortality and impacts on estimates of spawning escapement; one person saw his first dead fish in Long Harbour River this year.
- Most anglers in Newfoundland are meat hunters.

Specific

- Gander River: there was no sharp decline in the number of anglers on the river in 1994 as occurred in 1992 and 1993 when the river was closed to retention of catch.
- Campbellton River: people stopped fishing after the pre-July 31 quota of 3 retained fish was taken and did not hook and release in the remainder of July, but fished again in August for the remaining 3 fish for retention.

4. Effect of the 1994 management plan on angling effort and success.

- Some people indicated the Management Plan did not affect their usual pattern of angling while others felt that more effort was expended in August compared to previous years in order to catch the retention quota for that month.

5. Information on long-term population size in local area.

Specific

- Gander River: it was felt that run sizes to the Gander River were higher in the past and that fishing in 1993 was as good as any experienced in these earlier years. Several persons who had fished Gander River over a period of 30 years noted that population trends shown during the meeting were in general similar to their recollections in that population size was much higher in earlier years and that populations varied greatly from year to year.

## STEPHENVILLE, OCTOBER 18, 1994

## 1. Effect of 1994 water levels and water temperatures on angling success.

## General

- Some people suggested that there were lots of fish in SFA 13 in 1994 but they did not show up in the angling statistics because water levels were too high for fishing.
- Water levels went up in late July and angling success went down.

Specific

- Little Barachois Brook: water levels were extremely low in 1994.
- Southwest Brook: water levels were good in 1994.

## 2. Abundance of salmon in 1994.

## Specific

- Robinson's River: there were no fish in 1994 even when water levels were good. There were more large fish in 1993. This was the poorest year for Robinsons in 6-7 years.
- Middle Barachois: there were few fish early in the season in 1994. There was an extremely large run of herring size salmon around June 25 every year or two and also in Southwest in 1994.
- Flat Bay River: there is a bad poaching problem which reduces the estimated number of spawners.
- Grandy's Brook: this stock appears to be doing better than other south coast rivers such as Conne River.
- Barachois Brook: there were a lot of salmon in this river in 1994.
- Southwest Brook: fishing was good for a few days in early August. Abundance was low in 1994. There were good numbers of large fish in 1993 but lower numbers in 1994.
- Harry's River: good catches were reported from Dhoon Lodge. There seemed to be more fish in Harry's River this year (large and small) compared to previous years. Harry's was probably the exception for Bay St. George rivers. There is a lot of poaching inside the gut which would have affected returns to Harry's and Southwest Brook.

## 3. Change in angling habits due to hook and release.

## General

- Most people do not practice hook and release.

Specific

- Southwest and Bottom: the number of fish hooked and released in 1994 was low compared to previous years.
- Robinson's River: there was a good run of grilse during June 20-28. There were not as many fishermen in 1994 because of hook and release.

4. Effect of the 1994 management plan on angling effort and success.

- There has traditionally been very little angling in St. George's Bay rivers in August so having three tags in August would have affected the catch more than in other rivers with later runs.
- Misinterpretation of regulations (i.e., hook and release permitted with or without possession of at least one tag) resulted in reduced effort in 1994.
- SFA 14B: the reduction in bag limits for large salmon from 4 to 2 in SFA 14B rivers resulted in lower catches in 1994.

5. Information on long-term population size in local area.

- No information was provided at this meeting.

## 6. Other

- Some rivers such as Humber and Robinsons have a late run of salmon which would not be counted at the counting facilities resulting in under-estimation of spawning escapements from fence counts and angling catches.
- Fish enter some St. George's Bay rivers like Southwest Brook in May, before the recreational fishery and might not be picked up by anglers because they move to the upper parts of the watershed.
- Most grilse in rivers in SFA 13 are males.
- A lot of small parr about 2-3 inches in length were seen by anglers.
- In general anglers felt that in some rivers angling statistics did not reflect catches in 1994.

## PLUM POINT, OCTOBER19, 1994

## 1. Effects of 1994 water levels and water temperatures on angling success.

## General

- Water levels were moderate in July.
- Water warmed up in August and fishing was not as good as which temperatures were cooler.

## Specific

- Pinware River: water temperatures were cold in 1994 compared to previous years.
- St. Genevieve River: water levels were low at times.

## 2. Abundance of salmon in 1994.

## General

- CPUE may look worse than it really is because of a larger number of novice fishermen on the rivers. Many people who are out of work because of the cod fishery closure are buying salmon angling licences.

Specific

- St. Genevieve River: water levels were low in 1988 and 1994 resulting in fewer fish entering the river.
- Pinware River: large salmon usually enter the river early in the season but few fish were seen this year compared to previous years. Salmon numbers are declining in the Pinware. The fishery was a disaster this year compared to other years.
- SFA 3: there were lots of fish in 1994 in Main Brook, West Brook, Roddickton River, and Cloud River.

3. Changes in angling habits due to hook and release.

- Few people fished in this area during the hook and release fishery in 1992-94. There is not much interest in hook and release but it is increasing.
- There is no way of telling whether or not a fish is caught multiple times.
- Hook and release is causing an increase in effort because novice anglers who don't mind hook and release, fish all day for something to do.

4. Effect of the 1994 management plan on angling effort and success.

- The season split in tags did not change the time that most anglers started fishing because one could still hook and release.
- The season split in tags may have kept tourists away in 1994 because it was not worth the time and money to come for 3 fish.
- Most of the angling effort in this area was in July not August.
- Most people were not aware that they did not have to keep one tag in order to hook and release. This change in fishing regulations could have been communicated to anglers better than it was.

## 5. Information on long-term population size in local area.

## General

- Salmon stocks were higher in the 1970 s and lower now.

Specific

- St. Genevieve River: there were more and bigger fish than in previous years.

FORTEAU, OCTOBER 20, 1994

1. Effects of 1994 water levels and water temperatures on angling success.

- Water levels were perfect in 1994 but low in 1993.

2. Abundance of salmon in 1994.

## General

- One commercial fisherman commented that the eggs in large salmon that he caught in 1994 in SFA 14B were small compared to what he saw in other years. He also indicated that most of the fish he caught were large salmon. Hardly any small salmon were landed. Catches in the commercial fishery dropped off quickly in the third week of June. The same was observed in the fishery in Red Bay. The salmon were there when the season opened but dropped off after a few weeks and there were few caught after that. There were 13 commercial licences in SFA 14B in 1994; 2 or 3 licence holders did not fish in 1994 according to the local fisheries officer.

## Specific

- Forteau River: angling catch statistics were lower than the number actually caught. Angling in the past 10 years was better than in 1994. It was noted that there were some catches of slinks outside of the signs in Forteau River, which could affect returns of repeat spawners. There were no catches early in the season indicating that fish did not enter the river early. Large numbers of salmon caught in trout nets up north affect returns to Forteau River.
- Pinware River: angling statistics were lower than the number actually caught. Angling in the past 10 years was better than in 1994. Large numbers of seagulls were observed in the lower Pinware River and the lakes compared to previous years. They could be feeding on salmon parr because there is no fish offal at the fish plants since the closure of the cod fishery.

3. Changes in angling habits due to hook and release.

- People were concerned about hook-and-release fishing and the mortalities from it in 1994.

4. Effect of the 1994 management plan on angling effort and success.

- There was a general feeling that people did not fish as much because of the lower quota in 1994.

5. Information on long-term population size in local area.

- Salmon stocks were higher in the 1970s and lower now.

## CORNER BROOK, OCTOBER 24, 1994

1. Effects of 1994 water levels and water temperatures on angling success.

- Humber River: water levels were excellent in 1994 with some fluctuation at Big Falls, but good overall.
- Southwest Brook: water levels were good in 1994.

2. Abundance of salmon in 1994.

## General

- Salmon enter St. George's Bay rivers as early as May. Therefore, catch statistics cannot reflect total abundance of salmon because recreational fishing opens in early June.
- In general, it was pointed out by SPAWN that salmon stocks in St. George's Bay rivers were low.
- The fact that there is less poaching in St. George's Bay rivers in recent years compared to the 1970s may be because there are fewer fish now than in the past.

Specific

- Humber River: there were more fish in 1994 than in 1989 and number of fish in 1994 was similar to 1993. There were more fish at Big Falls in 1994 than in 1993. Fishing was good in 1994 at Big Falls. Catch levels indicated by the recreational catch statistics are generally too low. Catches at Big Falls were not all recorded by the creel survey clerks because some people sneaked fish out without tags. Some fishermen felt 1994 was a poorer year compared to 1993.
- Southwest Brook: fishing was better in June 1994 compared to 1993 but fewer large fish were seen. After mid-July, there were few if any fresh fish in the river. Therefore, fishing was worse in July and August 1994 than in previous years. There was no evidence of netted salmon. There are serious poaching problems in Southwest. Bottom Brook had a very low population this year.
- Harry's River: if the large salmon in Harry's are not going through the Pinchgut fence then they must be spawning in other tributaries. Angling statistics do not indicate the level of returns to the river in 1994. One angler said he hooked 21 fish in Harry's River this year which was one half the total catch reported by catch statistics. Few fish were seen at Home Pool in Pinchgut Brook in 1994.
- Robinson's River: "she's gone b'y she's gone".
- Barachois Brook: it is doing better recently. This is an early river with one run of fish early in the season.

3. Change in angling habits due to hook and release.

- Humber River: some anglers reported a lot of salmon were seen floating downstream at Big Falls which were attributed to hook-and-release mortalities. Others thought that these fish may have been killed from hitting the rocks below the falls rather than from hook and release. Some people also commented that they had seen no dead fish at Big Falls.

## 4. Effect of the 1994 management plan on angling effort and success.

- The seasonal tag split impacted on catches in 1994 since most fish in St. George's Bay rivers are traditionally caught before July 31. The season split would have meant only two fishing trips for experienced anglers.

5. Information on long-term population size in local area.

- no information was forthcoming at this meeting.

## SUMMARY

## 1. Effect of 1994 water levels and water temperatures on angling success:

- Most anglers felt that catchability was lower in 1994 due to low water levels and high water temperatures. The exceptions to this seemed to be some rivers in St. George's Bay, Humber River, Exploits River, Gander River, and rivers in Labrador.
- Low water levels and high water temperatures were reported for the northeast coast, Avalon Peninsula, the northwest coast, and SFA 14B rivers in southern Labrador.
- Overall it was felt that river closures due to extreme low water/high temperatures redistributed fishing effort from Avalon Peninsula rivers to other rivers on the island and in southern Labrador.

## 2. Abundance of salmon in 1994:

- Anglers felt that salmon held off entering Avalon Peninsula rivers due to high water temperatures.
- The abundance of salmon was low in southern Labrador in 1994.
- Several fishermen commented that anglers could not determine absolute stock abundance.

3. Change in angling habits due to hook and release:

- Hook-and-release fishing has increased over the years and is a confounding factor in comparisons involving historical angling data.
- Many anglers feel mortalities due to hook and release are high enough to affect assessment results.

## 4. Effect of the 1994 management plan on angling effort and success:

- It was the general conclusion that the 3:3 seasonal bag limit tag system (3 fish prior to and after July 31) eliminated the rush for fish noted in the 1992-93 seasons. Thus, 1994 catch and effort data are not comparable to that of 1992-93 but is more similar to previous years.
- Anglers expended more effort in August in 1994 than in the past, in an attempt to get the 3 post-July 31 fish.
- The seasonal tag split reduced the number of salmon caught overall because some rivers do not have salmon accessible to anglers in August.

5. Information on long-term population size in local area:

- Run sizes in many rivers were reported to have been higher in the past, similar to population trends analysis.
- Fish enter some St. George's Bay rivers like Southwest Brook in May before the recreational fishery and might not be picked up by anglers because they move to the upper parts of the watershed before the season opens.

6. Other:

- In general, anglers felt that DFO catch and effort statistics for angling are not accurate, generally being too low.

Appendix 2a. Atlantic salmon recreational fishery catch and effort data for Labrador (SFAs 1, 2, \&14B), 1974-1994. Ret. = retained fish; Rel. = released fish.

## 1987 DATA NOT INCLUDED IN MEAN.

in the above table a period indicates no data for that year.
CPUE IS BASED ON RETAINED + RELEASED FISH FOR 1992 AND 1993 AND ON RETAINED FISH ONLY PRIOR TO 1992.

* NOT ALLOWED TO RETAIN LARGE SALMON IN INSULAR NEWFOUNDLAND.

Appendix 2j. Attantic salmon recreational fishery catch and effort data for Salmon Fishing Area 4, insular Newfoundland, 1974-1994. Ret. $=$ retained fish; Rel. $=$ released fish.

## Appendix 3

## Sea-Survival-Rates for

## Campbellton River Salmon

Sea survival rates for 1993 smolt class
Smolt count - 1993 31,577

Adult count (small only) - $1994 \quad 2,857$
Sea survival rate - $1993 \quad 2,857 / 31,577=9.05 \%$

Previous spawners:

| Kelts (downstream) -1994 | 2,838 |
| :--- | :---: |
| Tagged kelts (downstream) - 1994 | 942 |
| Ratio untagged:tagged (total) | $2,838 / 942=3.01$ |
| Overwintering survival $-1993 / 94$ | $2,838 / 4,146=68.5 \%$ |

The following table is a summary of the estimated numbers of previous spawners in the small and large categories:

|  | UPSTREAM MIGRANTS |  | $\%$ <br> Previous <br> spawners |  |
| :--- | ---: | :---: | ---: | :---: |
|  | Tagged | Est. previous Total '94 <br> spawners | 20.0 |  |
| Small | 190 | 572 | 2857 | 20.6 |
| Large | 51 | 154 | 191 | 23.8 |
| Total | 241 | 726 | 3048 |  |

Sea survival rates with correction for previous spawners:

Smolt count - 93
Upstream grilse - 94
Corrected sea survival - 93
Previous spawners survival 3 mo.

31,577
2,285 (2,857-572)
$2,285 / 31,577=7.2 \%$
$726 / 2,838=25.6 \%$

Appendix 4. Newfoundland Region summary of the percent egg deposition requirement attained for various rivers during the five-year period prior to the commercial salmon fishery moratorium (1987-91) and the three years during the moratorium (1992-94).
