An assessment of the cod stock in NAFO Divisions 2J+3KL

by

P.A. Shelton, D.E. Stansbury, E.F. Murphy, G.R. Lilly and J. Brattey

Science Branch, Department of Fisheries and Oceans
PO Box 5667, St John's, Newfoundland
Canada, A1C 5X1

¹This series documents the scientific basis for the evaluation of fisheries resources in Atlantic Canada. As such, it addresses the issues of the day in the time frames required and the documents it contains are not intended as definitive statements on the subjects addressed but rather as progress reports on ongoing investigations.

Research documents are produced in the official language in which they are provided to the secretariat.

¹La présente série documente les bases scientifiques des évaluations des ressources halieutiques sur la côte atlantique du Canada. Elle traite des problèmes courants selon les échéanciers dictés. Les documents qu'elle contient ne doivent pas être considérés comme des énoncés définitifs sur les sujets traités, mais plutôt comme des rapports d'étape sur les études en cours.

Les Documents de recherche sont publiés dans la langue officielle utilisée dans le manuscrit envoyé au secrétariat.

Abstract

A moratorium on commercial fishing on this stock has been in effect since 1992. Although catches from a recreational fishery were relatively high in the year following the moratorium, catches over the last two years are thought to have been minimal. The Sentinel Survey resulted in a catch of about 330 t in 1995. This catch was submitted to intensive biological sampling. Autumn research vessel survey indices of cod biomass and abundance in divisions 2J3KL have indicated severe declines in recent years. The 1995 estimate cannot be compared directly with the preceding estimates because of a change in survey gear and vessel, however the mean catch per tow remained exceptionally low throughout the survey area in 1995. There is some indication from mean weights at age in both the Sentinel Survey catches and the trawl survey that the downward trend has been reversed in the most recent years. Of particular concern in the assessment of this stock is the absence of any indication of good recruitment.

Resumé

Un moratoire de la pêche commerciale de ce stock est en vigueur depuis 1992. Bien que les prises récréatives étaient relativement élevées l'année suivant la mise en place du moratoire, on croit qu'elles étaient faibles au cours des deux dernières années. Les pêches de contrôle ont donné des prises d'environ 350 t en 1995, prises qui ont été soumises à un échantillonnage biologique exhaustif. Les indices de la biomasse et de l'abondance de la morue obtenus dans le cadre du relevé de recherche d'automne effectué dans les divisions 2J3KL accusent une baisse marquée dans les dernières années. L'estimation de 1995 ne peut être comparée directement avec les estimations précédentes, les engins et les bateaux utilisés pour les relevés n'étant pas les mêmes. Toutefois, les prises moyennes par trait sont demeurées exceptionnellement faibles dans toute la zone du relevé en 1995. Le poids moyen selon l'âge obtenu des pêches de contrôle et du relevé au chalut indique dans une certaine mesure un renversement de la tendance à la baisse dans les dernières années. L'absence de signes d'un bon recrutement est particulièrement inquiétant.

Introduction

The cod stock in NAFO divisions 2J3KL had declined to very low biomass levels by 1977 when Canada extended jurisdiction to 200 miles. This decline was primarily a result of heavy fishing by foreign fleets in the offshore during the 1960s and early 1970s. Increased fishing effort by Canadian trawlers in the offshore resulted in increasing catches following extension of jurisdiction. This occurred over a time period which coincided with the entry of the strong 1973, 1974 and 1975 year classes to the fishery and a strongly increasing trend in fish growth rates following low growth in the early 1970s.

There was sufficient escapement over this period to allow the spawner biomass to partially rebuild from 1978 to 1981. However, the 1976 and 1977 year classes were very weak and fish growth rates decreased in the early 1980s so that the spawner biomass began to decline after 1982.

The 1978 to 1982 year classes ranged from moderate to strong (1981), however these year classes experienced slow growth rates (particularly in 1984 and 1985) and increasing fishing mortality by Canadian effort in both the inshore and offshore. The strength of the following two year classes is uncertain. Survey data up to age 4 suggest that these yearclasses were relatively strong but surveys after 1991 failed to confirm this interpretation. Several hypotheses are compatible with the observations, including systematic sampling error (so-called year effect in the data) and high mortality (natural mortality or unreported deaths due to fishing). Fish growth rates remained low over this period while catches continued to increase until the late 1980s. The stock collapsed to exceptionally low levels by the early 1990s.

A moratorium was imposed on directed commercial fishing in July 1992. Although catches from a recreational fishery were relatively high, given the state of the stock, in the year following the imposition of the moratorium, catches over the last two years are thought to be less than 2,000 t.

The current assessment updates the status of the stock under the moratorium, adding to the information contained in Bishop et al. (1995) and Bishop et al. (1994). The expectation is that the stock will eventually recover as a result of the virtual elimination of fishing activity, however the rate at which it will recover cannot be predicted. It is anticipated that it will take at least several more years because all recent year classes appear to have been weak.

Nominal catch

Nominal catches for this stock increased during the late 1950s and early 1960s and peaked at just over 800,000 t in 1968 (Table 1, Fig. 1). Catches declined rapidly thereafter and were at a low of 139,000 t in 1978. From 1982 to 1990 catches were above 200,000 t but declined to 172,000 t in 1991 before imposition of the moratorium on commercial fishing in July of 1992. During the 1960s when the fishery was dominated by non-Canadian fleets (Fig. 2) most of the catches occurred in Div. 2J and 3L with 2J dominating. Since that time catches have been mainly from Div. 3K and 3L (Fig. 3).

The fixed gear fishery maintained and even increased its catches over the 1980s to a peak of 117,000 t in 1990 (Table 2, Fig. 4), however not all these landings came from the inshore. Gillnet catches in the offshore, most notably on the Virgin Rocks (Div. 3L) increased rapidly in the late 1980s to a peak of 22,000 t in 1990 before declining (Table 3).

A recreational fishery together with bycatches accounted for 11,000 t in 1993. A limited (10 days) food fishery during August and September, together with bycatch, accounted for about 1,000 t of landings in 1994. In 1995 a Sentinel Fishery was introduced to continue to provide some data from commercial inshore fixed gear (Davis et al. 1996). Sentinel catches and a small amount of bycatch from the few continuing fisheries resulted in reported landings of less than 1,000 t in 1995. The Sentinel Fishery landings occurred predominantly from June to November and were dominated by gillnet catches in Div. 3K and 3L (Table 4).

Catch and weight at age

A summary of the sampling from the Sentinel Fishery used to estimate the catch at age in 1995 is given in Table 5. A total of about 10,000 fish were measured for length and more than 5,000 otoliths were read for age, representing much more intensive sampling than would normally be directed at a commercial catch. The samples are well distributed across divisions, months and gears.

The estimated catch, average weight and average length at age from the Sentinel Fishery and the bycatch for 1995 are given in Table 6. The following relationship was applied in deriving average weight at age:

$$\text{Log(weight)} = 3.0879 * \log(\text{length}) - 5.2106.$$

Coefficients of variation for the estimated catch at age were less than 10% for ages 2 to 7. The 1990 and 1989 year classes were most abundant in the Sentinel Fishery catches for 1995.

The age composition and mean length at age for the various fishing gear which participated in the Sentinel Fishery is given in Table 7. Trap selectivity, both in terms of age and length at age are lower than the equivalent values for gillnet. Line trawl and handline catches also comprised a greater proportion of younger fish than did gillnets.

The catch numbers, average weights and biomass at age for the years 1962 to 1992 are presented in Tables 8 to 10. Although the modal ages class has remained relatively constant over the time period (ages 5 - 7) the disappearance of the older fish in the catches is very marked, particularly over the last 10 years (Table 8, Fig. 5).

Weights at age for the 1962 to 1971 period are estimates obtained using data for 1964 to 1968 from Div. 2J and 1965 to 1970 from Div. 3KL weighted by divisional catch. Weights at age are calculated from annual mean lengths at age and a constant length-weight relationship (given above). A plot of the data for 1972 to the present (Fig. 6) shows that although weights at age in the catch increased in the late 1970s they declined throughout the 1980s to low levels by the 1990s. There is some indication of an increase in the most recent two years.

In addition to the reported catch at age, Kulka (1996) estimated the time series of discarded catch at age (Table 11). Although the estimated discards are generally an order of magnitude less than the nominal catch, the increase in the estimates of young fish in the discards over the late 1980s is of interest and the impact on catch at age analysis should be investigated.

Sentinel Survey

In addition to providing catch at age data for an analytical assessment, the Sentinel Survey provided information on catch rates and fish condition. These results are discussed in detail in Davis (1996) and are only summarized here.

The 1995 Sentinel Survey indicated that the catch rates were lower than the last year of the commercial fishery off Labrador and the Northern Peninsula, same as the last year in White Bay, higher than the last year in Notre Dame Bay, and variable in Trinity Bay, Conception Bay and eastern Avalon. Fishers involved in the survey cautioned that high catch rates in some areas may have been a consequence of the lack of competition among gear because of the low levels of effort involved. Sentinel fisher and biological sampling of the catch both indicated that fish in the 1995 Sentinel catch were in good condition.

Inshore surveys

A large concentration of spawning cod was found in Smith Sound, Trinity Bay in 1995. Hydroacoustic work in May 1995 suggested a biomass of around 17,000 t (Rose 1996). Samples in December 1995 showed that the fish were mainly aged 3 to 8 and in good condition. Samples in April 1996 found them to be spawning again (Brattey 1996). The April 1996 survey also revealed adult cod in Northwest Arm and Southeast Arm, Trinity Bay. Unusually high parasite incidences suggested that these cod had resided in the inshore throughout the fall and winter months (Brattey 1996). Acoustic estimates of the biomass of cod in all three arms of Trinity Bay from the April 1996 survey are being prepared.

Research vessel trawl survey data

Research vessel surveys have been conducted by Canada during the autumn in Div. 2J, 3K and 3L since 1977, 1978 and 1981 respectively. No survey was conducted in Div. 3L in 1984, however the results of the summer (August - September) survey have been used in assessments. The 1995 autumn survey continued into late February 1996. Spring surveys have been conducted by Canada in Div. 3L for the years 1971 to 1982 and 1985 to 1995. Surveys in Div. 2J3K were conducted by RV Gadus Atlantica (up to 1994) while those in Div. 3L by RV A.T. Cameron (1971-82) and RV Wilfred Templeman (1983-1995 for spring and 1983-1995 for autumn). The autumn survey in Div. 2J3K in 1995 was conducted mainly by RV Teleost, although RV Templeman surveyed part of Div. 3K.

In the autumn 1995 survey both the RV Teleost and RV Templeman used the Campelen 1800 trawl gear, replacing the Engels 145 high rise trawl gear. The selectivities of the two nets were tested through intensive comparative fishing experiments in 1995 and 1996 and their selectivities were found to be markedly different (Warren 1996). Application of the conversion of Engels catches to Campelen equivalents are explored in Stansbury (1996).

The survey stratification scheme is based on depth contours. The strata used in 1995 are shown in Figs. 7-9. Schemes for the allocation of sets among strata has varied considerably among years. Prior to 1988 set allocation was proportional to stratum area. In 1989 and 1990 an "adaptive design" was introduced in an attempt to minimize variance, but was replaced with a design in which set allocation is based on past observed stratum variance (Gagnon 1991) in 1991 to 1994, followed by a return to allocation based on stratum area in 1995.

To account for incomplete coverage of strata in certain years, estimates of biomass and abundance for non-sampled strata were obtained using a multiplicative model. Because of apparent distributional changes in cod in recent years, the change in the stratification scheme in 1993 (Bishop 1994), and the change in vessel and trawl gear in 1995, this correction was last applied in 1991.

Cod abundance and biomass estimates by division, stratum and trip are given in Tables 12 to 19 for the autumn surveys and Tables 20 and 21 for the spring surveys. The time series of autumn abundance and biomass for Div. 2J, 3K and 3L surveys are plotted in Figs. 10 to 12. The decline in numbers and biomass in all 3 divisions is clear after 1989 and recent values are the lowest on record. Despite the fact that the catch in the most recent survey is not corrected for the greater catchability of the younger ages by the new trawl gear, the 1995 estimate is not significantly different from the previous two years.

The autumn time series of numbers per tow at each set location are mapped in Fig.13 for the period 1981 to 1995. For the period 1981 to 1988 catches were wide-spread over the survey area. Commencing in 1989 changes started to occur in that fewer cod were found near the coast. Over the period 1990 to 1991 the remaining fish became increasingly limited to three areas offshore in deep water - Hawke Channel in 2J, Belle Ilse Bank/Funk Island Bank, and the area between Funk Island Bank and Grand Bank. By the autumn of 1992 only the southern concentration remained although apparently reduced in extent. This concentration appeared to be further reduced in both extent and average density in 1993 and no concentrations were encountered in the 1994 and 1995 surveys.

The stratified mean numbers per tow at age by division are given in Tables 22 to 24 for the depth range that has been consistently sampled over the time period (i.e. not including the strata deeper than 500m in 2J and 3K and 200 fathoms in 3L). The combined Div. 2J3KL stratified mean numbers per tow as well as the associated coefficients of variation are given in Table 25. The overall decline and contraction of the age composition after 1989 in 2J and one or two years later in the 3K and 3L is striking.

Analysis

Sequential population analysis

A formulation of ADAPT, the adaptive framework for sequential population analysis (Gavaris 1988) was applied to the survey mean numbers at age (Table 25) and catch at age (Table 8).

Parameters estimated in the ADAPT were:

Population numbers

$N_{i,t}$ where $i = 3$ to 12, $t = 1995$,
and Catchabilities

K_i where $i=3$ to 12.

Structure imposed was:

- (i) natural mortality assumed to be 0.20,
- (ii) fishing mortality on the oldest age (12) set to be equal to the mean for ages 7-9,
- (iii) no error in the survey mean numbers at age,
- (iv) no error in the catch numbers at age.

Input data were:

Catch numbers at age

$$C_{i,t} \quad \text{where } i = 3 \text{ to } 12 \text{ and } t = 1978 \text{ to } 1995$$

and Research Vessel survey estimates of mean numbers at age

$$RV_{i,t} \quad \text{where } i = 3 \text{ to } 12 \text{ and } t = 1978 \text{ to } 1995.$$

The objective function which was minimized was

$$\sum_{i,t} (\ln(RV_{i,t}) - \ln(K_i N_{i,t}))^2.$$

The results are summarized in Table 26. There are strong year effects in the residuals as well as a possible age effect. Residuals in the last three years are generally negative whereas those for 1989 to 1992 are generally positive. This indicates that the model is having trouble fitting the data, specifically the rapid decline in the survey in the most recent years.

These estimates would be considered "illustrative" of the population dynamics, but not sufficiently well estimated to allow the projection of stock size under different levels of fishing mortality. Nevertheless, the general values and trends in numbers at age and fishing mortality at age give a reasonable representation of what are thought to be the dynamics of the stock and the pattern of fishing in the post 1977 period.

In the ADAPT reconstruction, numbers at age 4 and older declined in the early part of the time series and then recovered as a consequence of the strong year-classes that entered the 3+ population in the early 1980s (Fig. 14). When recruitment fell to lower levels thereafter, there was a sequential decline in the numbers at age accelerated by the rapidly increasing fishing mortality. Fishing mortality increased slowly throughout the 1980s, but at an increased rate after 1978 to a peak in the early 1990s (Fig. 15). Note that despite the moratorium being introduced in 1992, the recreational fishery in 1993 yielded relatively high fishing mortalities.

Spawner stock and recruitment

Using the ADAPT estimates of numbers at age in Table 26 and beginning of year weights at age estimated from the commercial catches (Table 27), the beginning of year 3+ biomass can be calculated (Table 28). By applying the estimated beginning of year proportion mature at age (females) from Morgan and Brattey (1996) (Table 29, Fig. 16) the mature biomass can be estimated (Table 30). The convention of applying the female proportions mature to the total male plus female population was followed.

The ADAPT reconstruction suggests that the 3+ biomass reached a peak for the post-extension of jurisdiction period in 1985 and that there has been a steady decline thereafter (Fig. 17). Spawner biomass estimated using knife-edge recruitment at age 7 and using the proportion mature at age estimated by Morgan and Brattey (1986) are reasonably similar and suggest that the spawner biomass was nearly constant over the period 1982 to 1988, whereafter it declined very rapidly.

The spawner biomass estimated using the maturity data and the ADAPT estimates of 3 year olds are depicted as a scatter plot in Fig. 18 with the years joined in sequence. The relatively low recruitment values for the 1987 and subsequent cohorts at intermediate to low spawner biomass compared to the 1978 to 1980 year classes which arose from similar

spawner biomass levels reflects a strong time-dependent signal in the data in addition to any spawner biomass signal. Attempts have been made to capture this pattern in the recruitment data using nonparameteric stock recruit models with time as one of the variables (e.g. Shelton and Morgan 1994). This time-dependence, a sort of depensatory or "non-stationary" effect in a sense, may have implications for stock recovery.

Multiplicative model analysis of survey data

Estimate of cohort strength were obtained following the general approach of Sinclair and Chouinard (1991) by fitting the following general linear model to the survey mean numbers per tow data for Div. 2J3KL combined (Table 25):

$$\log(N_{i,j,k,t}) = \tau + \alpha_i + \beta_j + \gamma_k + \varepsilon$$

where

$N_{i,j,k,t}$ = mean numbers per tow of age i using net type j , belonging to cohort k at the time of the autumn survey in year t

τ = intercept,

α_i = age effect for $i = 1\dots13$ and $i = 1\dots3$ in two separate formulations,

β_j = survey net type effect where $j = 1$ for non-Campelen gear and $j = 2$ for Campelen gear,

γ_k = cohort effect,

and ε = residuals from the fitted model.

The predicted cohort strengths were then back-transformed (bias not corrected) and plotted against the numbers at age 3 estimated by ADAPT for the equivalent cohort (Fig. 19). It is clear that there is a close resemblance between the multiplicative model fitted to ages 1-13 and ADAPT estimates of relative year class size. One difference is in the estimates of the 1986 cohort which ADAPT indicates is relatively strong, whereas the multiplicative model suggests that it is not. The multiplicative model does, however, indicate that the 1987 yearclass is stronger than those yearclasses on either side. Note that the multiplicative model and ADAPT do not provide independent estimates because both depend on the survey data. The main difference is that the ADAPT accounts for the catches whereas this version of the multiplicative model does not. The strength of the 1986 and 1987 yearclasses is very controversial.

If the multiplicative model is applied only to ages 1 to 3 (i.e. as above but with $i = 1\dots3$, Fig. 19) then the 1987 yearclass appears to be comparable to the 1973-75 and 1981-82 yearclasses. However the interpretation of yearclass strength from information on a cohort from only a few ages is very susceptible to the problem of year effects in the survey data. The presence of such year effects for the period 1989 to 1992 is indicated by the positive residuals in the ADAPT formulation (Table 26). This could be interpreted in two ways - either the survey estimates in the preceding and following years are too low, or the estimates over the period 1989 to 1992 are too high. This assumes that the catch data are accurate, that natural mortality is constant and that immigration and emigration are negligible. These assumptions may be wrong. This problem has not yet been resolved.

Estimate of relative total mortality were obtained by fitting the following general linear model to the survey mean numbers per tow data for Div. 2J3KL combined (Table 25):

$$\log(N_{i,j,k,t}) = \tau + \beta_j + \gamma_k + \alpha\gamma_k + \varepsilon$$

where

$N_{i,j,k,t}$ = mean numbers per tow of age i for $i=3$ to 8, using net type j, belonging to cohort k at the time of the autumn survey in year t

τ = intercept,

α = age effect ,

β_j = survey net type effect where $j = 1$ for non-Campelen gear and $j = 2$ for Campelen gear,

γ_k = cohort effect,

and ε = residuals from the fitted model.

The separate slopes parameter estimates ($\alpha\gamma_k$) are plotted as relative estimates of the average mortality experienced by a cohort over age 3 to 8 (Fig. 20). The plot shows a decrease in total mortality on the 1972 to 1978 cohorts followed by a trend of increasing mortality on the subsequent cohorts up to the 1987, as Canadian fishing effort replace the foreign effort in the offshore. The decline in total mortality on the more recent cohorts can be explained by a combination of events, including the change to the Campelen net in 1995, the effect of the moratorium from 1992 onwards, and the partial recruitment to the fishery of the younger ages.

Spawner biomass per recruit

Spawner biomass per recruit (age 3) at $F = 0$ ($SPR_{F=0}$) and at the F estimated in the ADAPT (Table 26) ($SPR_{F=F}$) were carried out using the annual weights at age estimated from the commercial samples (Table 27) and the maturity at age (Table 29). The SPR estimates (Fig. 21) suggest that for the cohorts from 1965 to 1995 $SPR_{F=0}$ varied between about 4 kg and 6.5 kg with a declining trend over the 1970 to 1980 cohorts and an increasing trend for cohorts subsequent to the 1985 cohort. $SPR_{F=F}$ was relatively constant at a value of about 1 kg for cohorts up to about the 1975 cohort and then declined steadily to very low values for the mid-1980's cohorts. The subsequent increase in $SPR_{F=F}$ is a result of the combination of changes in F (moratorium), growth and maturity. Note that all estimates for incomplete cohorts are based on assuming that values of fishing mortality, weight and maturity at age measured in the last year pertain for the remainder of the cohort's lifetime.

As a biological reference point, $SPR_{F=F}/SPR_{F=0}$ is sometimes calculated and expressed as a percentage (%SPR). A reference point can then be chosen and fishing mortalities adjusted to remain above this level. The values for %SPR are plotted in Fig. 22. It is clear that %SPR steadily declined for all cohorts between the 1973 and 1986 cohorts, reaching very low levels, before increasing again for recent cohorts.

Survey lengths and weights at age

Mean lengths at age (Table 31a) were calculated as in recent years by weighting individual measurements in the biological sample by the ratio of the total survey catch per 3 cm length class to the number of fish sampled in that length class. The sampling of fish for length at age was length-stratified within each Division (Shelton and Lilly 1995), so it may be more appropriate to weight each individual measurement by the ratio of the population number per 3 cm length class to the number of fish sampled in the same length class, where the population number is calculated by areal expansion of the stratified mean catch at length per tow (Smith and Somerton 1981). Mean lengths at age calculated in this manner are provided in Table 31b and Fig. 23.

Mean weights at age (Table 32a) were calculated as in recent years by applying a standard weight/length relationship to the mean lengths at age shown in Table 31a. A few adjustments have been made to the table as it appeared in the previous assessment document (Bishop et al. 1995; Table 18). For Div. 3K, small corrections were applied to the data for 1991. For Div. 3L, the numbers in the age column have been incremented by 1. For example, in 1981 the weight at age of 0.20 refers to cod of age 2, not age 1. In addition, data for Div. 3L in 1984 have been deleted. These data came from a summer survey which was part of planned seasonal surveying. There was no autumn survey in 1984.

An alternative to using a standard weight/length relationship is to use the actual weights of those fish weighed at sea or frozen at sea and weighed after thawing in the laboratory. In most years, sample sizes for weights were much smaller than sample sizes for lengths (Shelton and Lilly 1995), but using the actual weights has the advantage of accounting for variability in weight at length. Alternative mean weights at age (Table 32b; Fig. 24) were calculated by weighting each individual fish weight by the ratio of the population number at length to the number of fish sampled at length.

As noted above, mean weights at age for cod caught in the commercial fishery declined during the 1980s and early 1990s after peaking in the late 1970s or early 1980s. The research sampling illustrates that the changes varied with Division; there was a strong decline in Div. 2J, a lesser decline in Div. 3K, and little or no decline in Div. 3L. These Divisional differences are more apparent in Fig. 25, which focuses on changes in mean lengths and weights of cod of ages 4 and 6. Superimposed on the long-term decline are periods of relatively quicker or slower growth associated with changes in water temperature (Shelton and Lilly 1995). The trend toward very low mean lengths and weights at age in the early 1990s appears to have been reversed, but sample sizes have been very small in recent years.

Summary

There is little doubt that the Division 2J3KL cod stock remains at very low level. There is no indication of a strong yearclass which could form the basis for a recovery. The trawl surveys and the Sentinel Survey catches show that there are very few fish older than age 9 in the population. Several relatively strong yearclasses followed by good survival are required to rebuild the population. Even then, it will take a number of years before the spawner biomass recovers to a level at which the stock could be considered to be out of immediate danger, provided a cautious management approach is adopted. The only significant aggregations of fish that have been surveyed in the last two years are in the inshore areas of Trinity Bay (Brattey 1996). More aggregations of similar size may exist in the other major bays but this has not been determined and would require initiating a new trawl and hydroacoustic survey to complement the trawl survey that covers the shelf outside 12 miles.

¹ Provisional catches.² Includes French catch and an estimate of foreign catch by Canadian surveillance.³ Figure is 4000 t less than Canadian statistics as this amount is considered 3NO catch misreported as 3L.⁴ Derived from reported catch and Canadian surveillance estimate for foreign catch.⁵ Includes 5000 t catch from the recreational fishery after the moratorium was declared.⁶ Canadian surveillance estimates of foreign catch.⁷ Includes a 5053 t catch estimated for the recreational fishery additional to that recorded by Canadian statistics.⁸ 1300 t is from the food fishery the remainder is by catch⁹ Catch includes 163 t caught in the sentinel fishery and 168 t caught as bycatch.

Note shaded numbers are estimates for non sampled strata and only 0-500 m strata are used in deriving these estimates.

nf =not fished

¹ not all strata fished² total and mean no. per tow include sampled and estimated values for depths to 500 meters. Estimates were derived from a multiplicative model using survey data to 1991.

nf strata not fished

¹Totals and means presented are for all strata fished. Because of the short time series with the new stratification scheme and a change in vessel and gear in 1995 no attempt has been made to fill for missing strata.²Survey gear changed from Engels 145 to Campelen 1800.

Table 18 . Cod abundance estimates (thousands of fish) from research vessel surveys in NAFO Division 3L (Fall).

Note shaded numbers are estimates for non sampled strata and only 0-200 fathom strata are used in deriving these estimates.

nf not fished

¹ not all strata fished² Total and mean no. per tow include sampled and estimated values for depths to 200 fathom. Estimates were derived from a multiplicative model using survey data to 1991.³ Survey gear changed from Engels 145 to Campelen 1800.

Note shaded numbers are estimates for non sampled strata and only 0-200 fathom strata are used in deriving these estimates.

nf not fished

* not all strata fished

* Total and mean no. per tow include sampled and estimated values for depths to 200 fathom. Estimates were derived from a multiplicative model using survey data to 1991.

Table 32a. Average weight (kg) at age of cod caught during autumn bottom-trawl surveys in Div. 2J3KL in 1978-1995.
 These weights were calculated from the mean lengths at age (Table 31a) using a standard weight/length relationship.

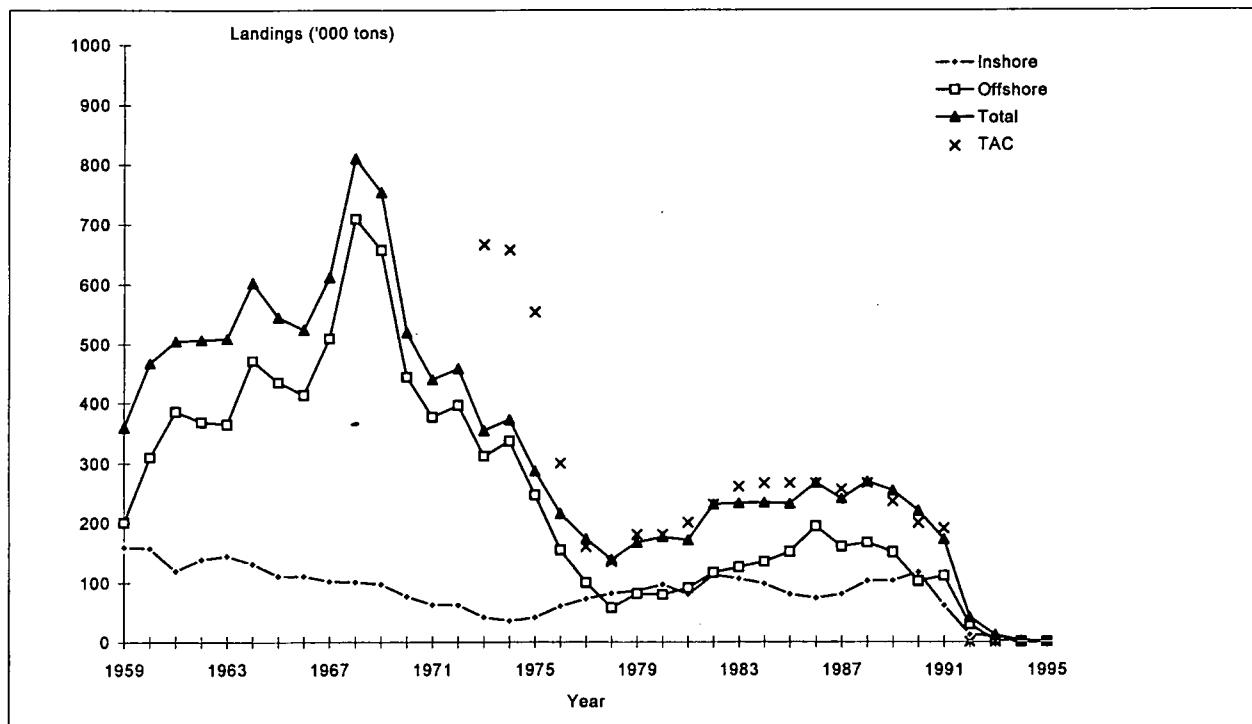

Fig. 1. Inshore landings, offshore landings and TAC for Divisions 2J3KL.

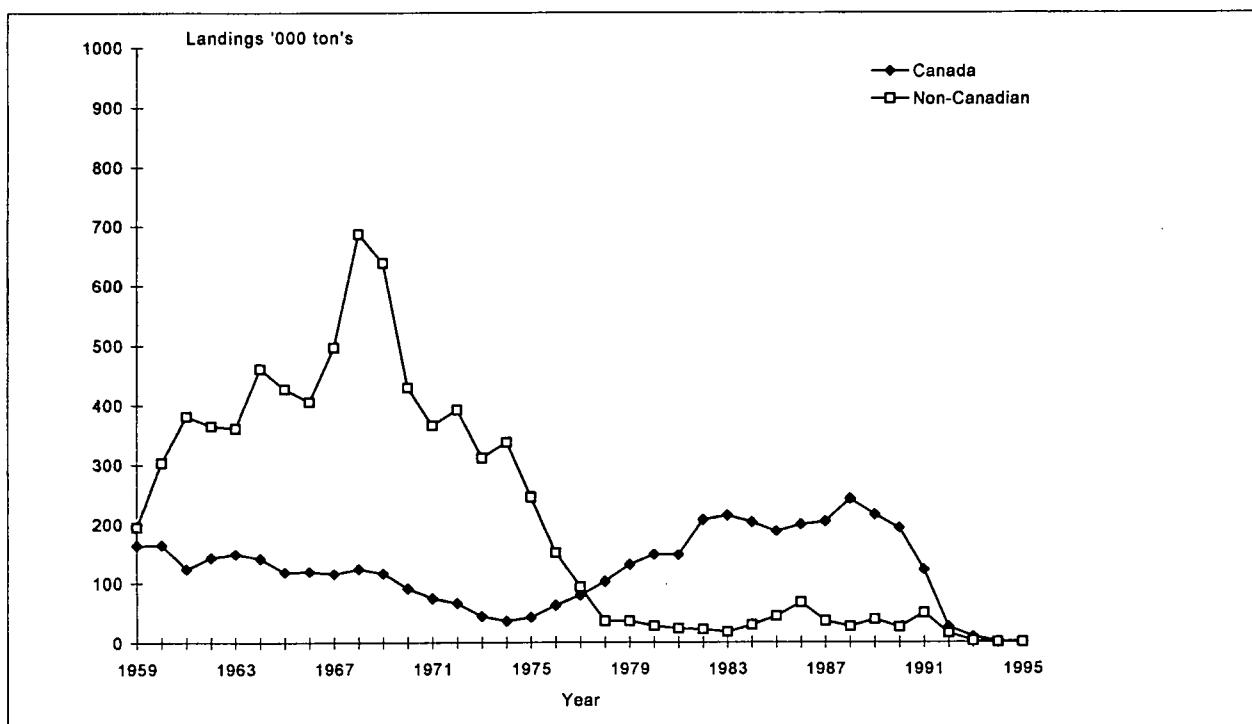

Fig. 2. Landings of cod in Divisions 2J3KL by Canadian and other vessels.

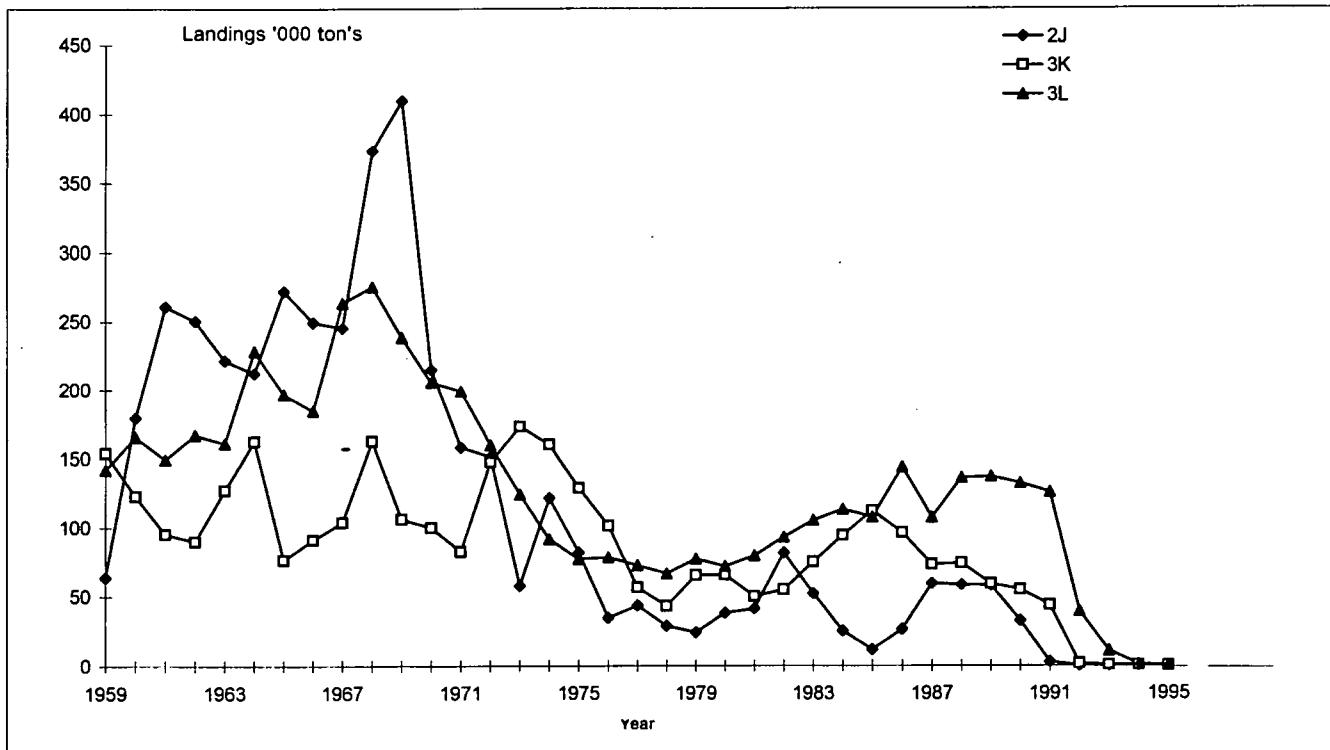

Fig. 3. Divisions 2J3KL cod landings by division.

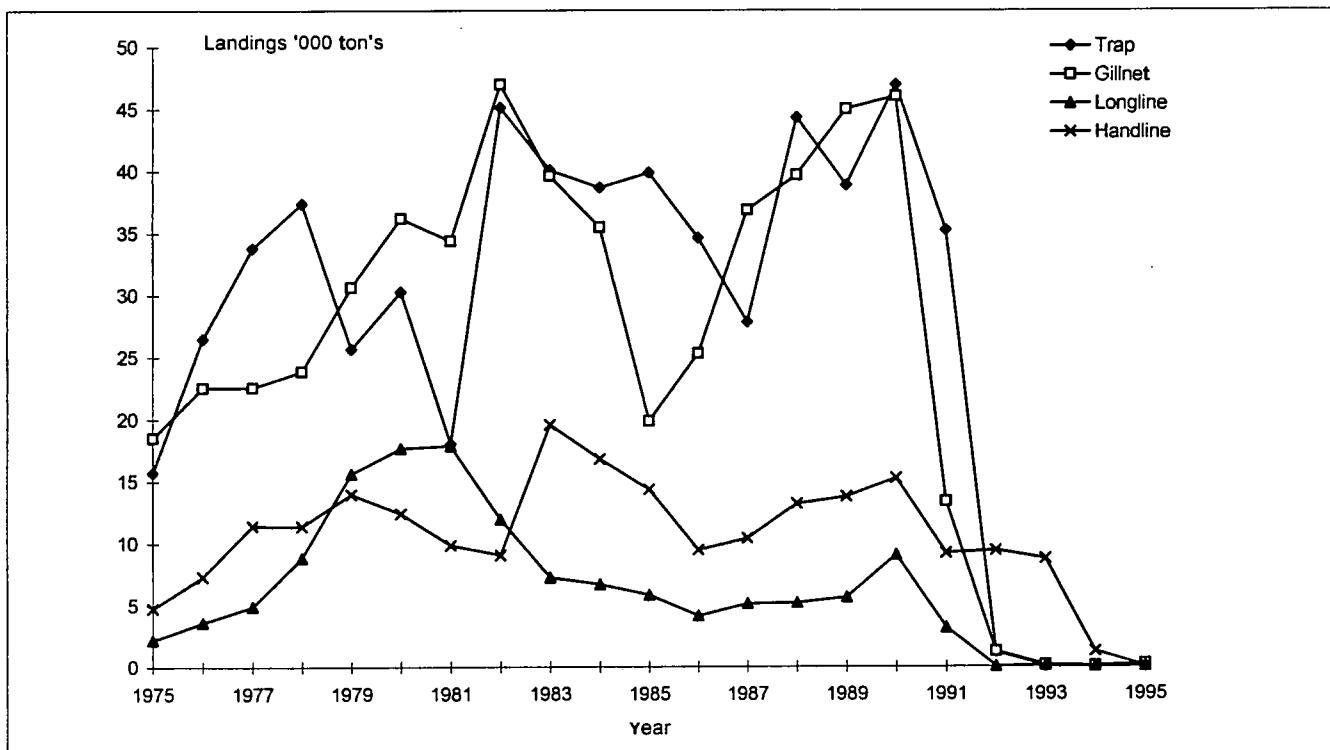

Fig. 4. Divisions 2J3KL inshore cod landings by gear type.

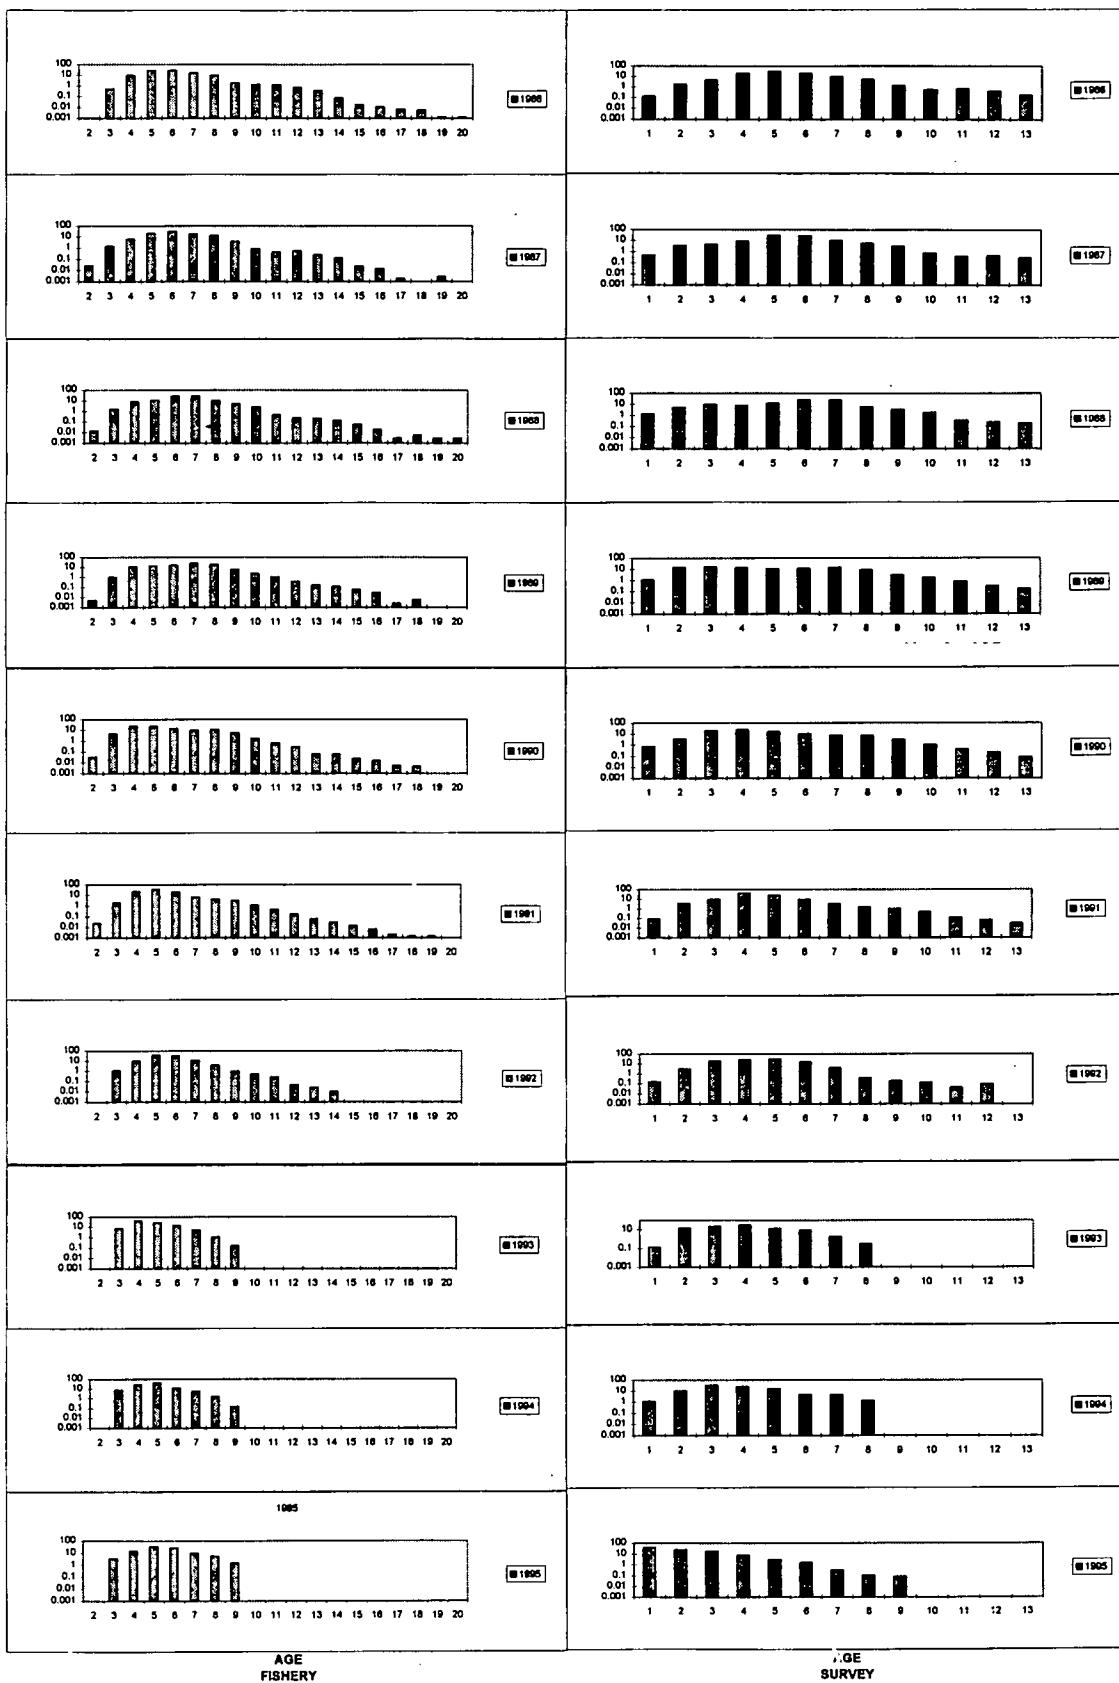

Fig. 5. Logarithm of the annual proportion at age in the commercial landings and the research survey catches of cod for the years 1986 to 1995.

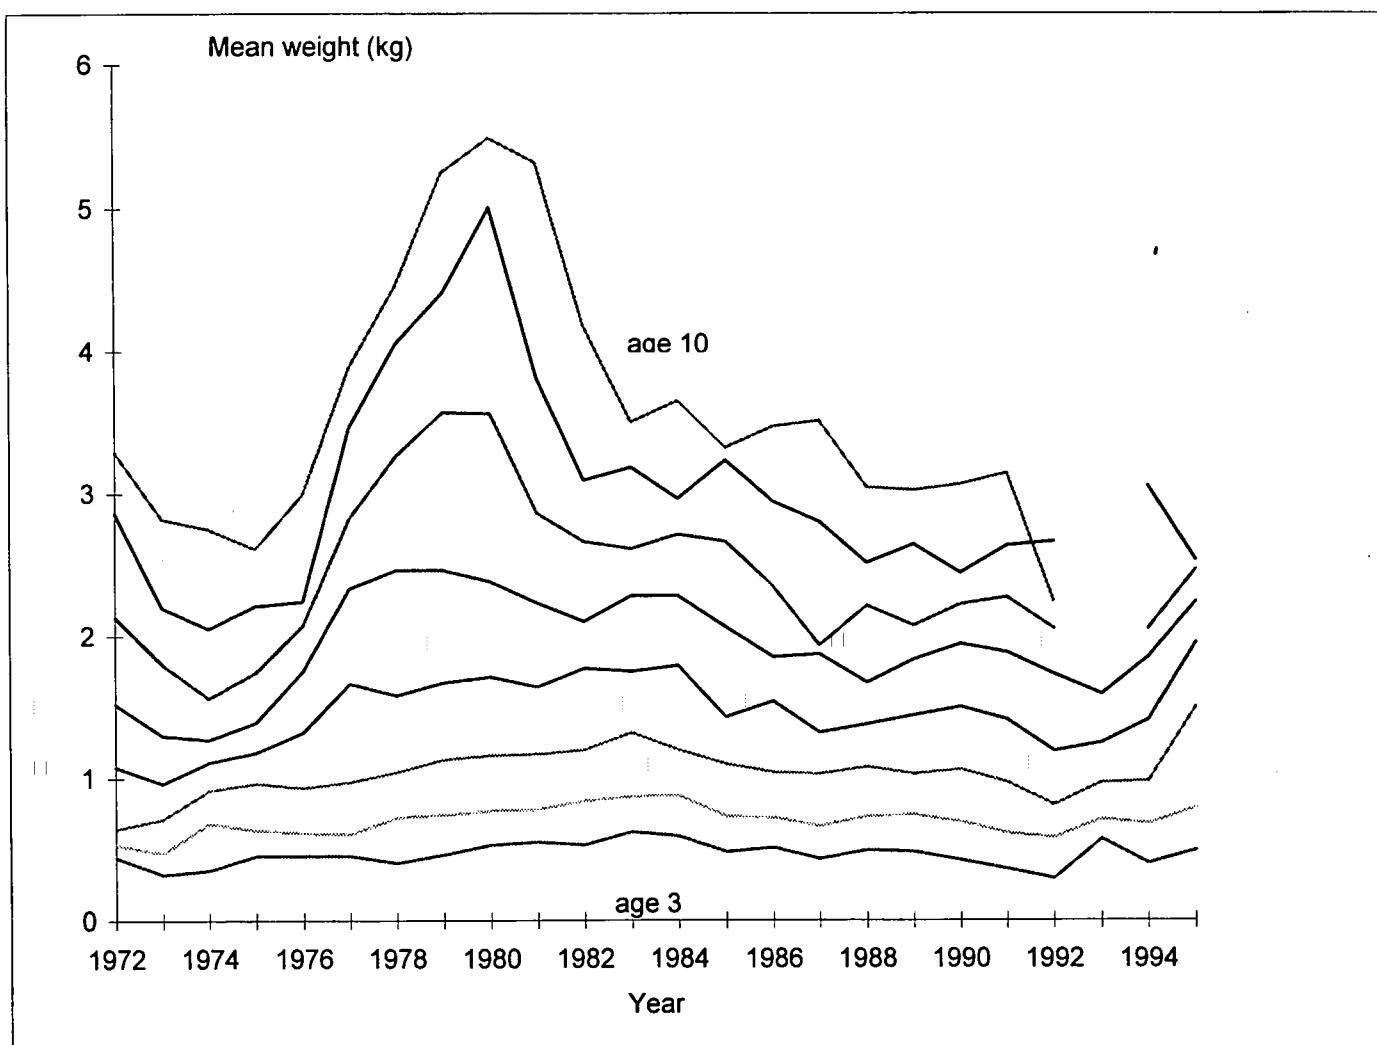

Fig. 6. Mean weights at age in the Division 2J3KL commercial catches of cod.

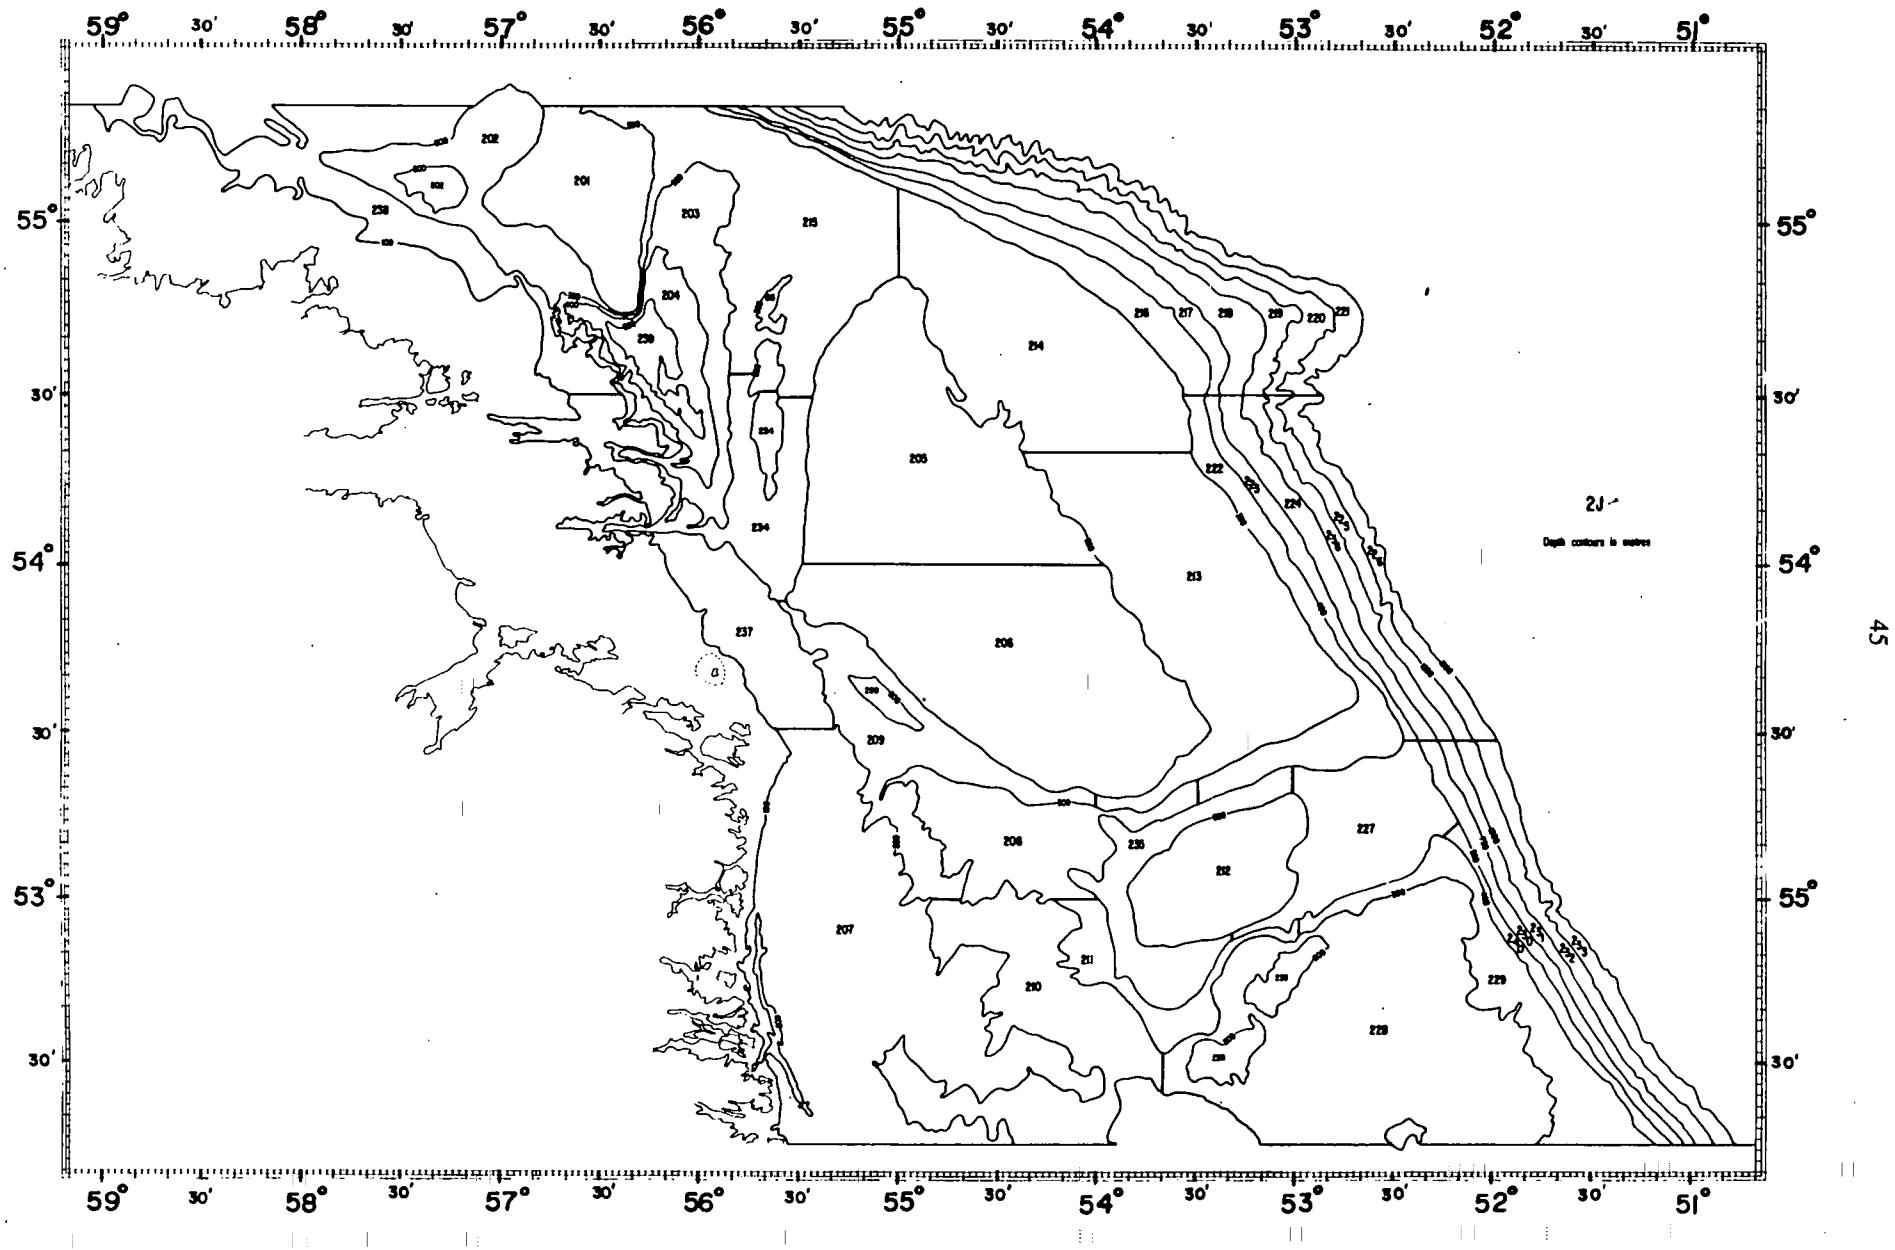

Fig. 7. Area of stratification for RV surveys in NAFO Division 2J.

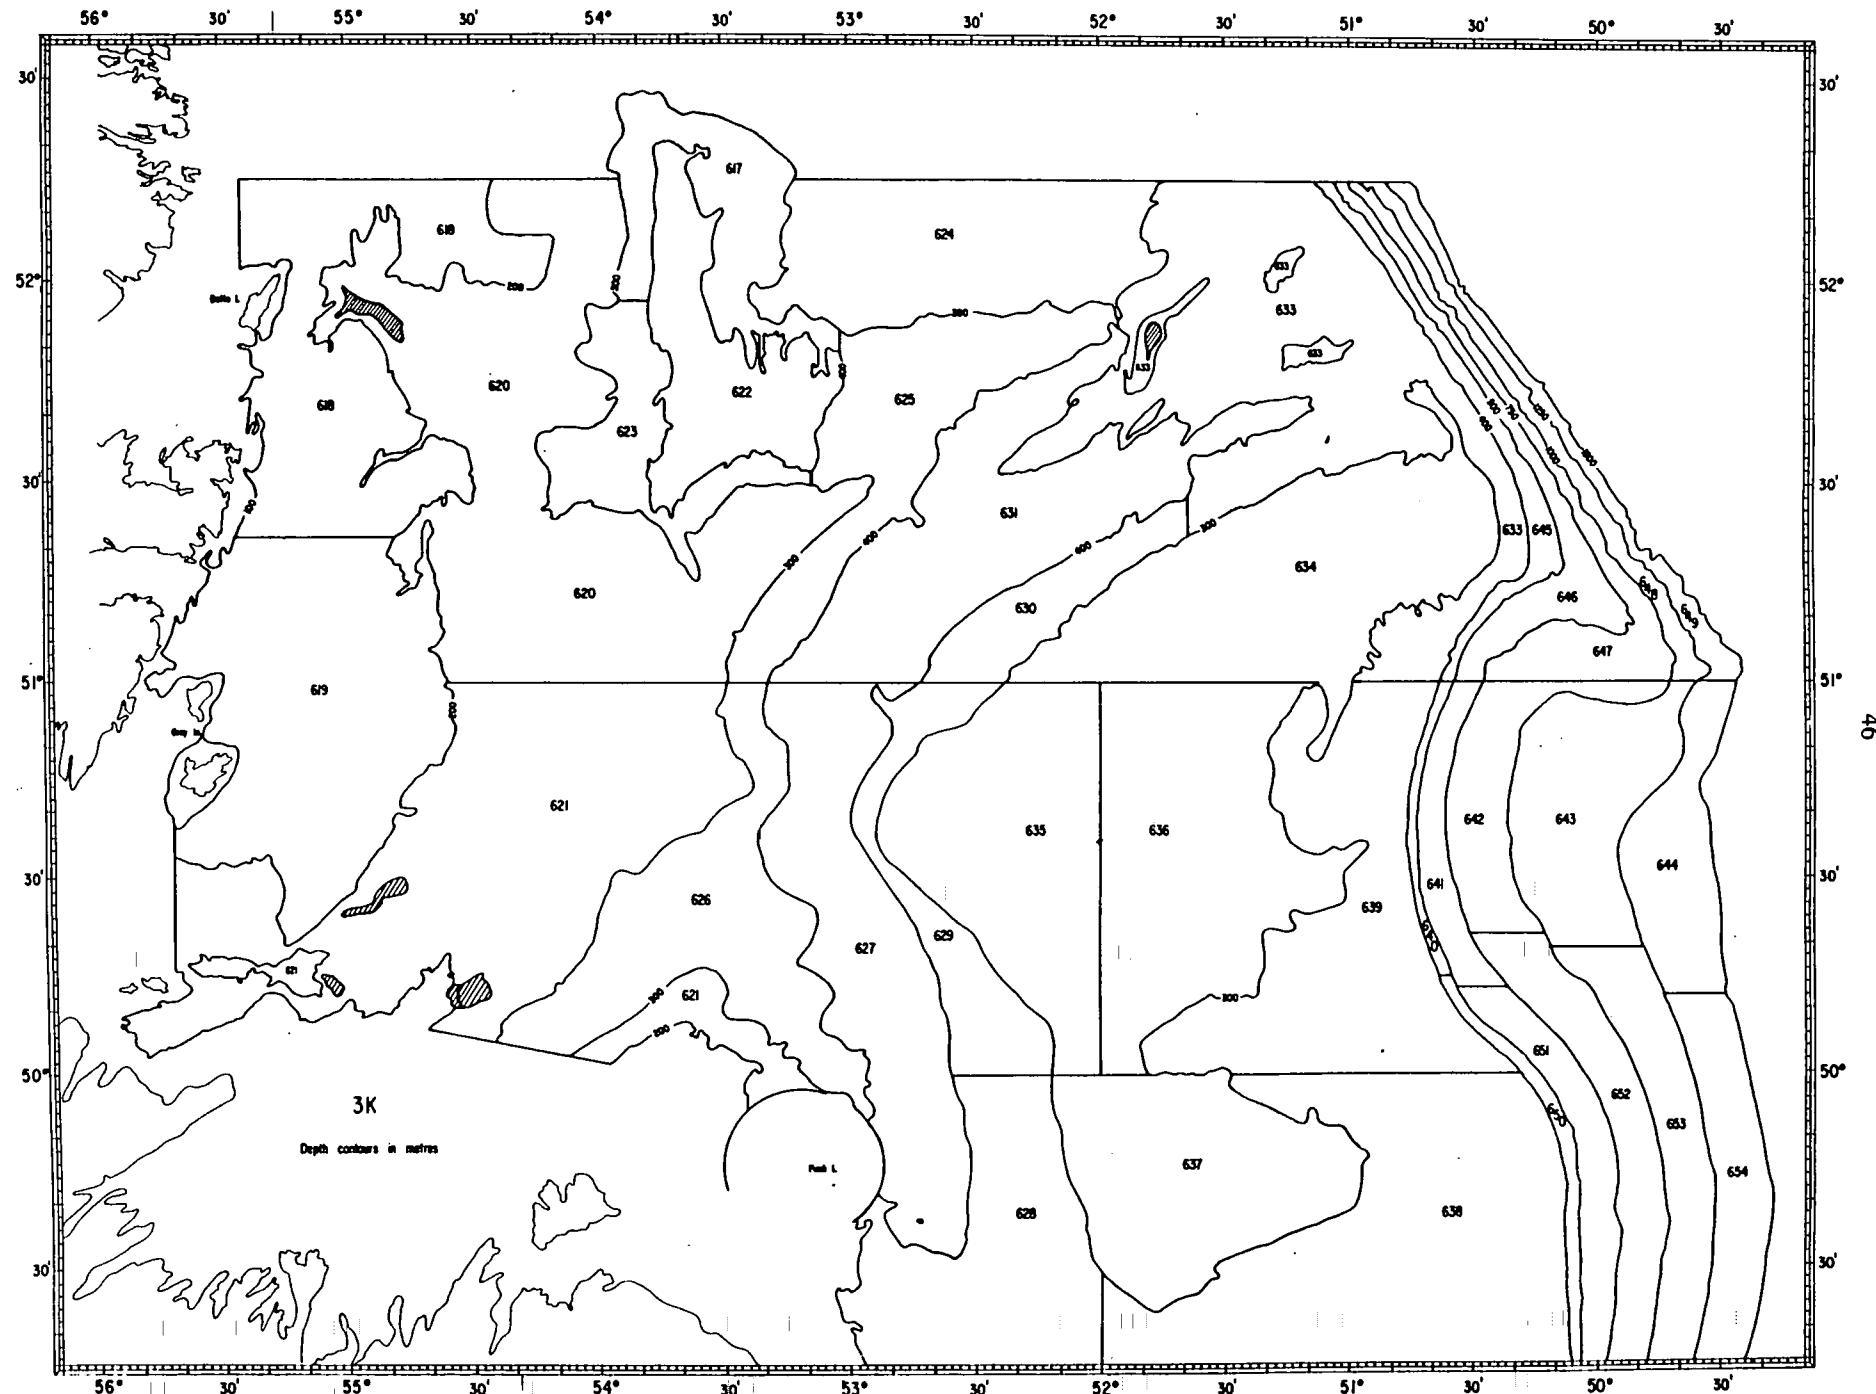

Fig. 8. Area of stratification for RV surveys in NAFO Division 3K.

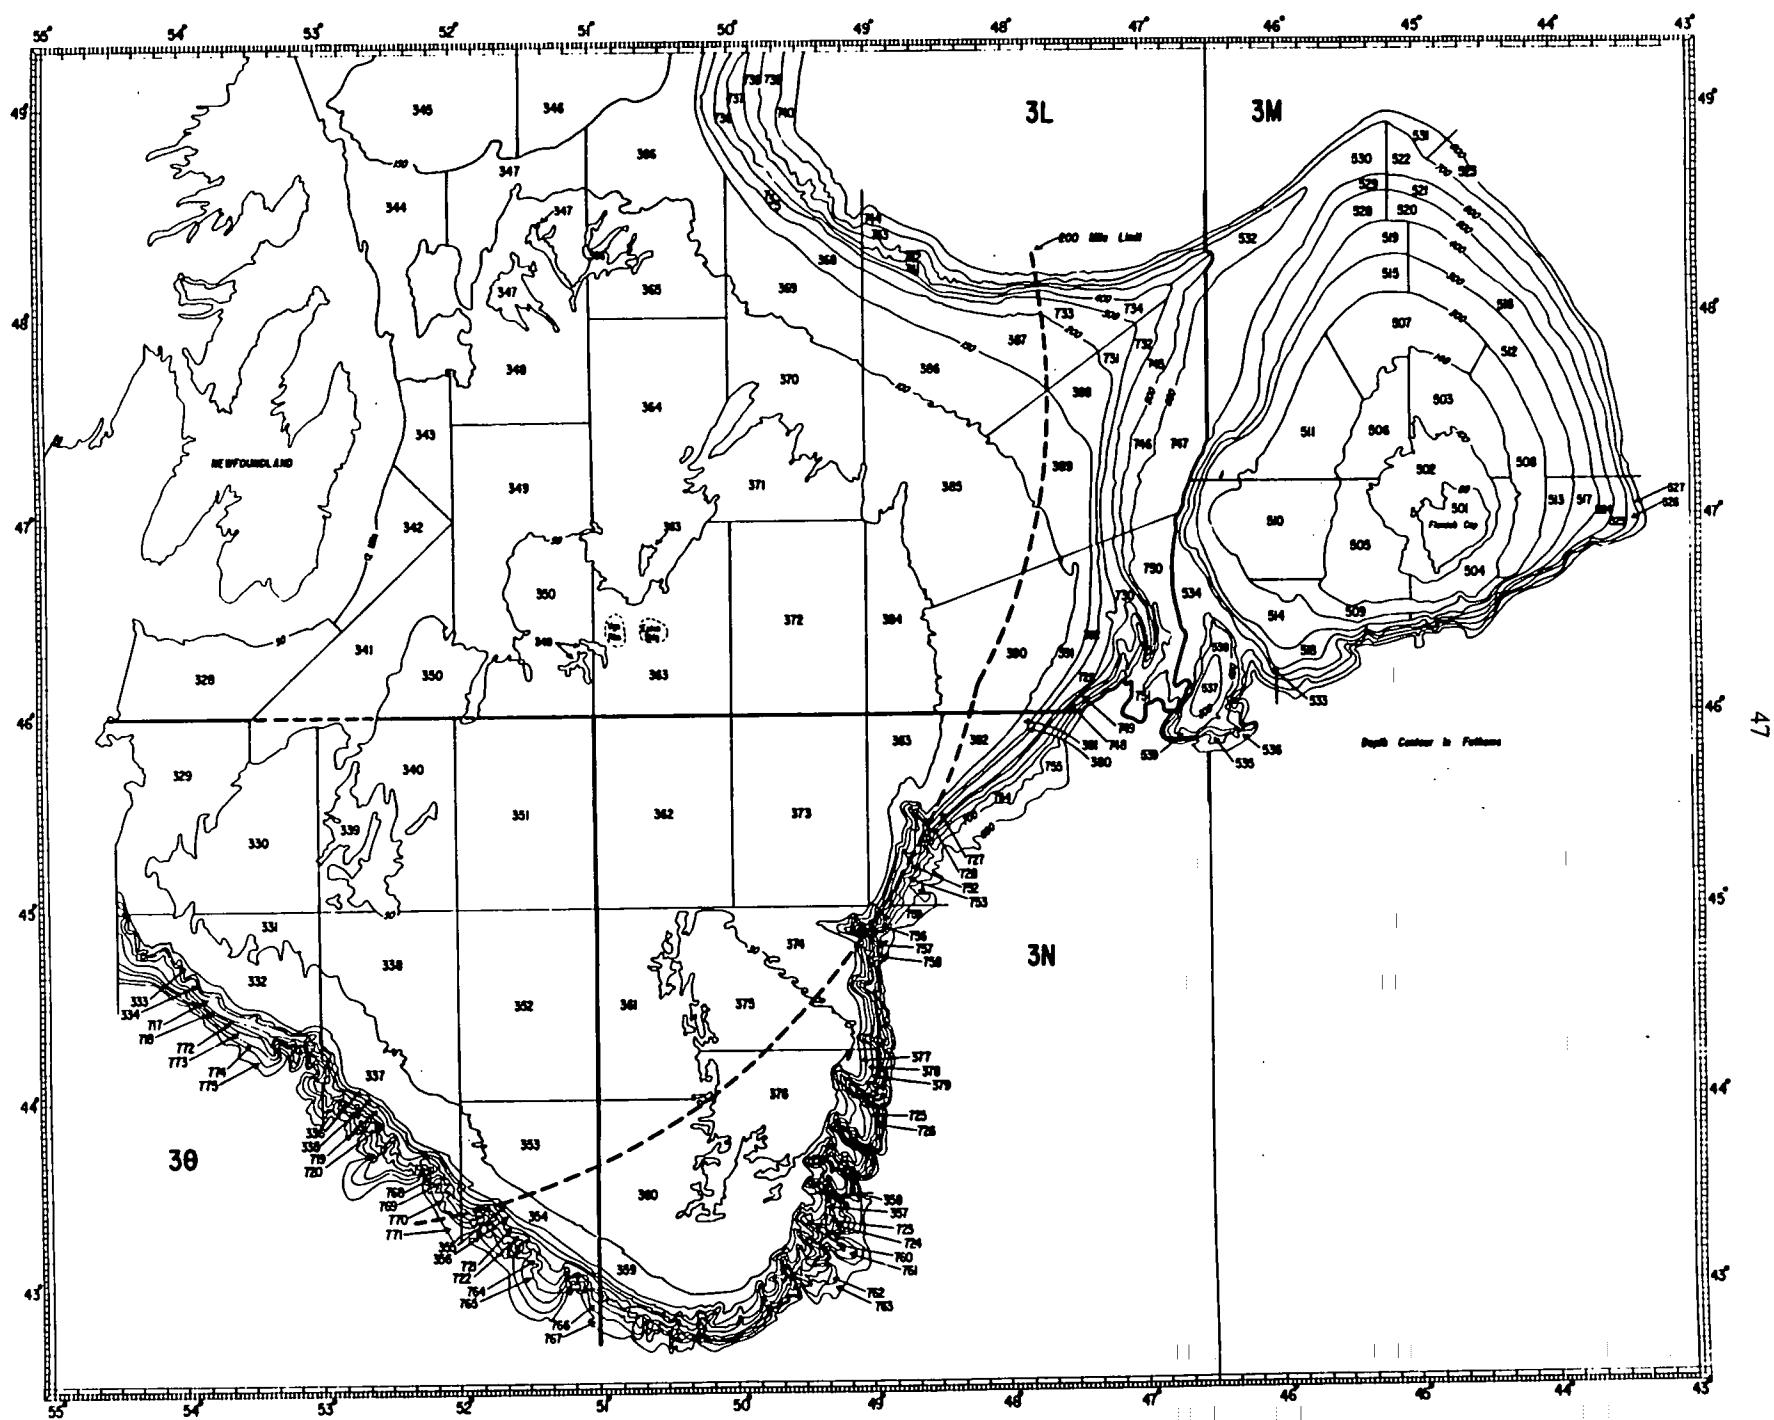

Fig. 9. Area of stratification for RV surveys in NAFO Division 3L.

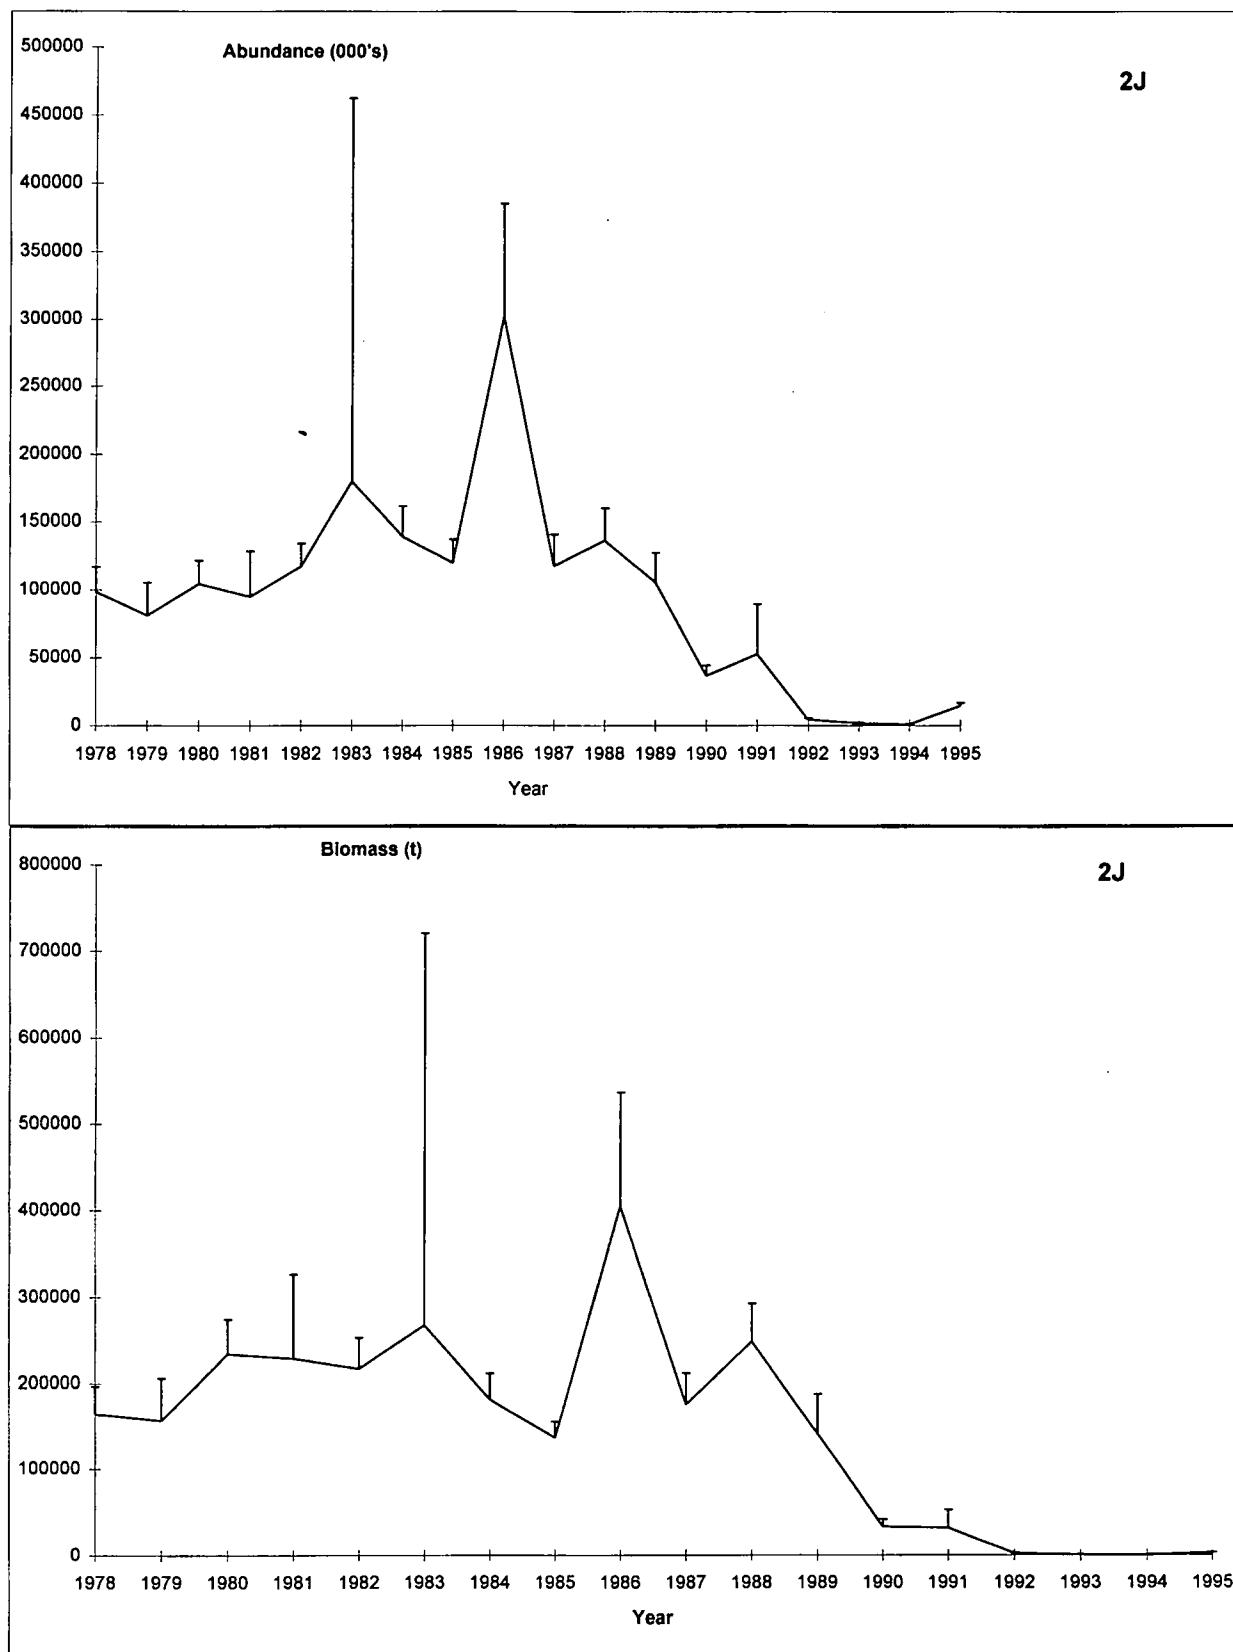

Fig. 10. Annual estimates of abundance and biomass for the autumn RV trawl survey in Division 2J. Vertical bar indicates one standard error.

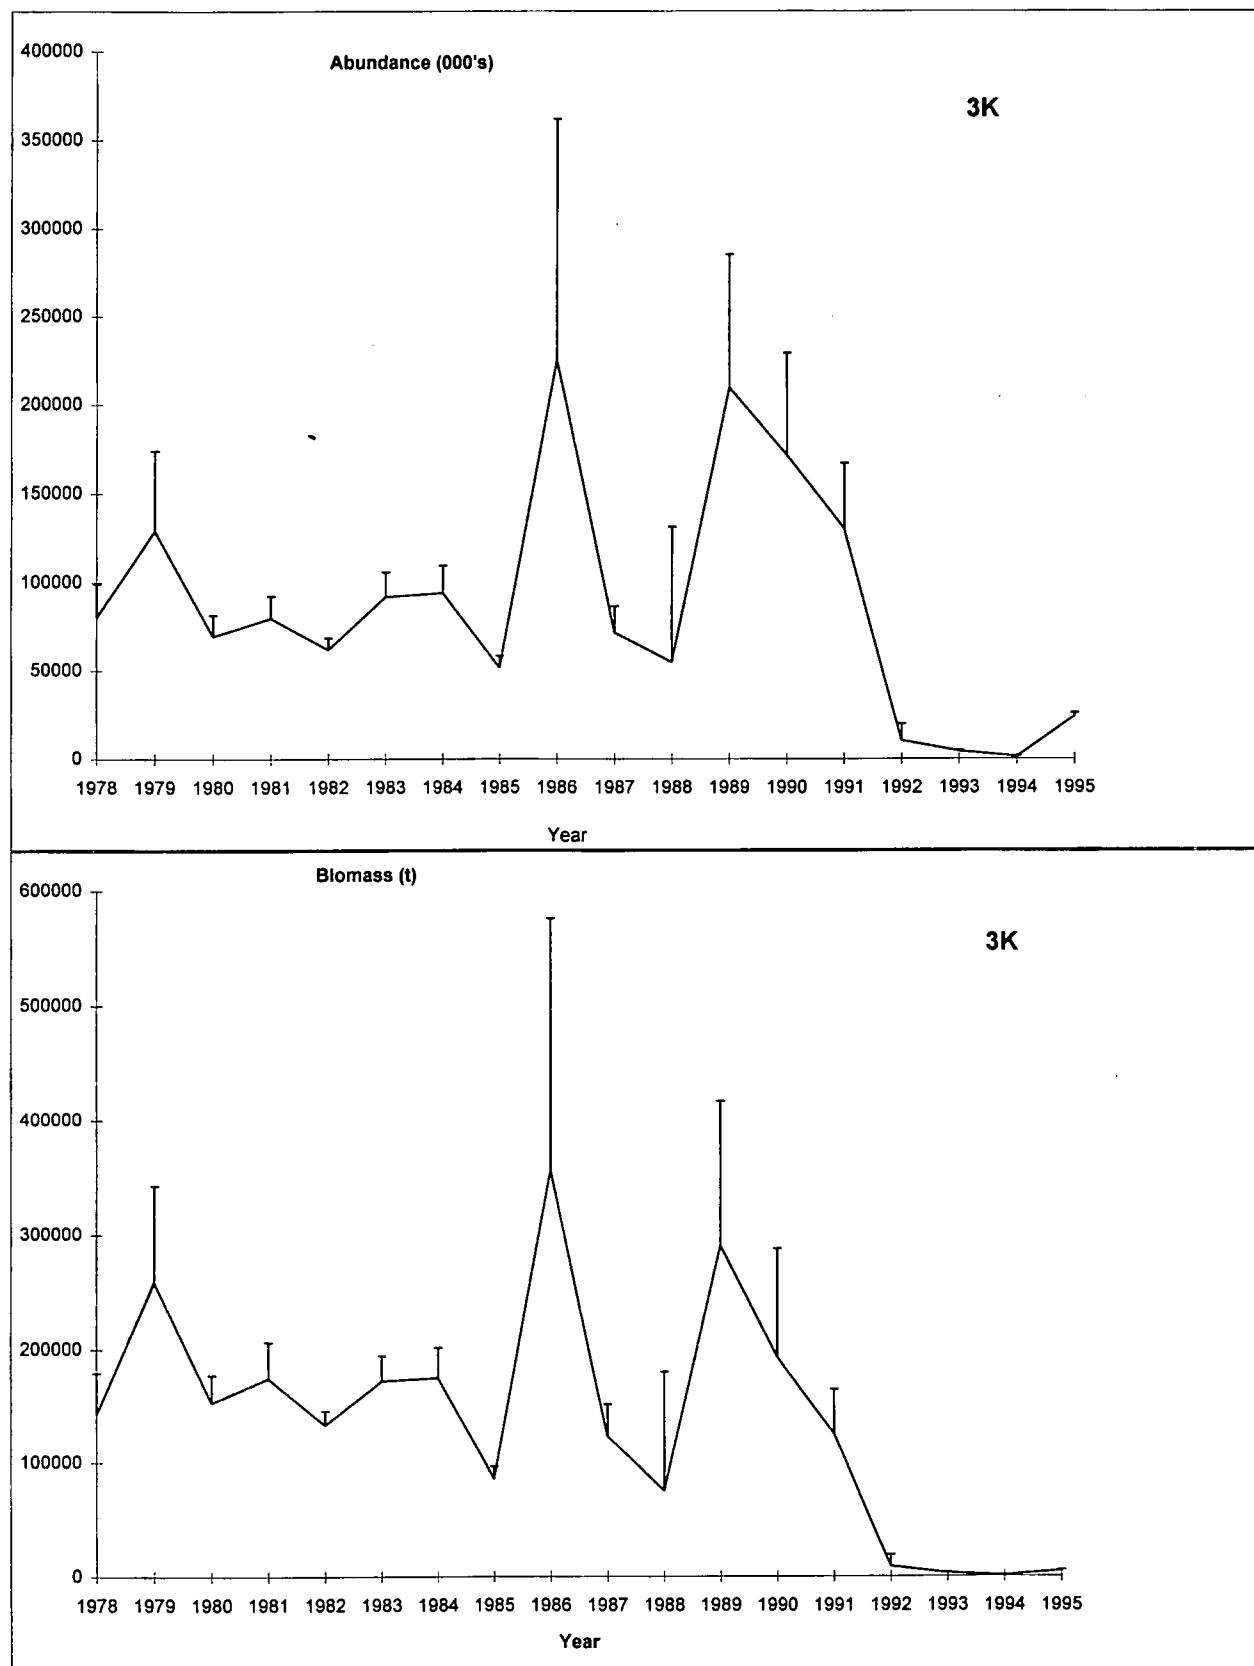

Fig. 11. Annual estimates of abundance and biomass for the autumn RV trawl survey in Division 3K. Vertical bar indicates one standard error.

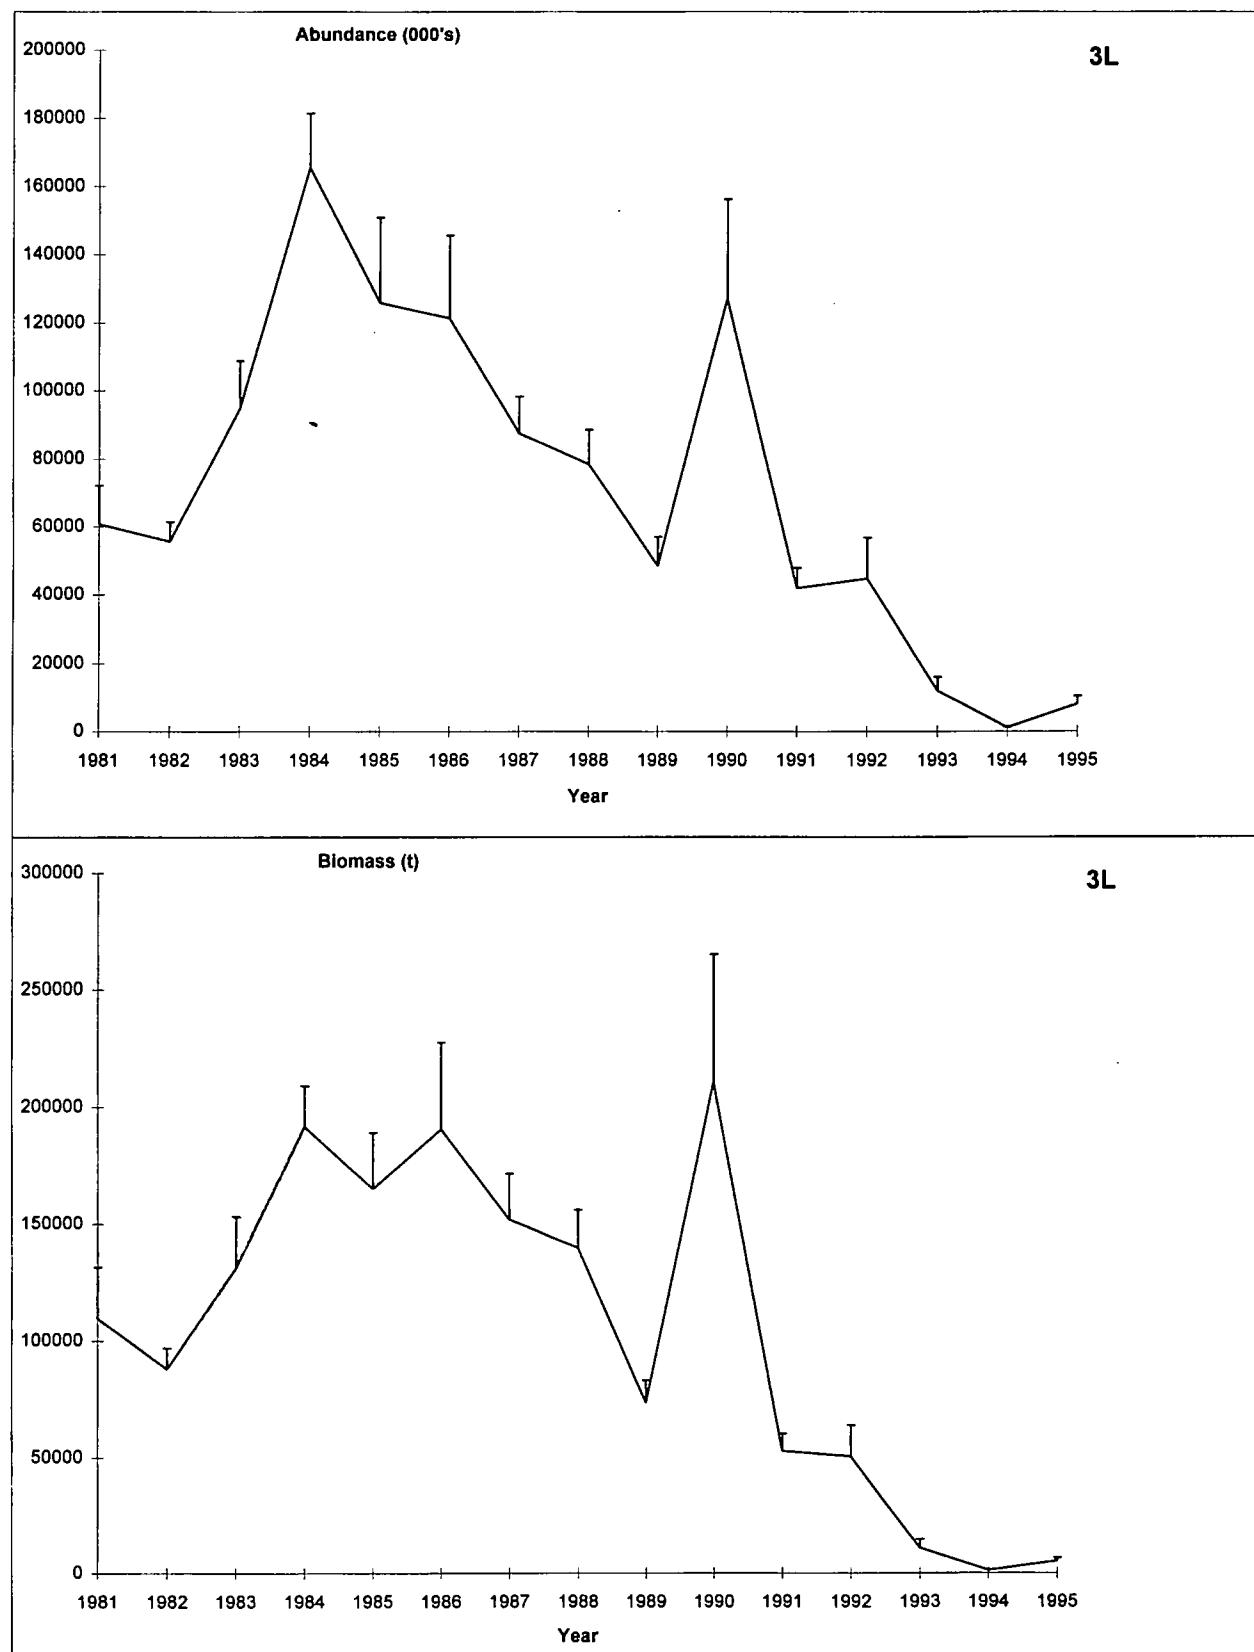

Fig. 12. Annual estimates of abundance and biomass for the autumn RV trawl survey in Division 3L. Vertical bar indicates one standard error.

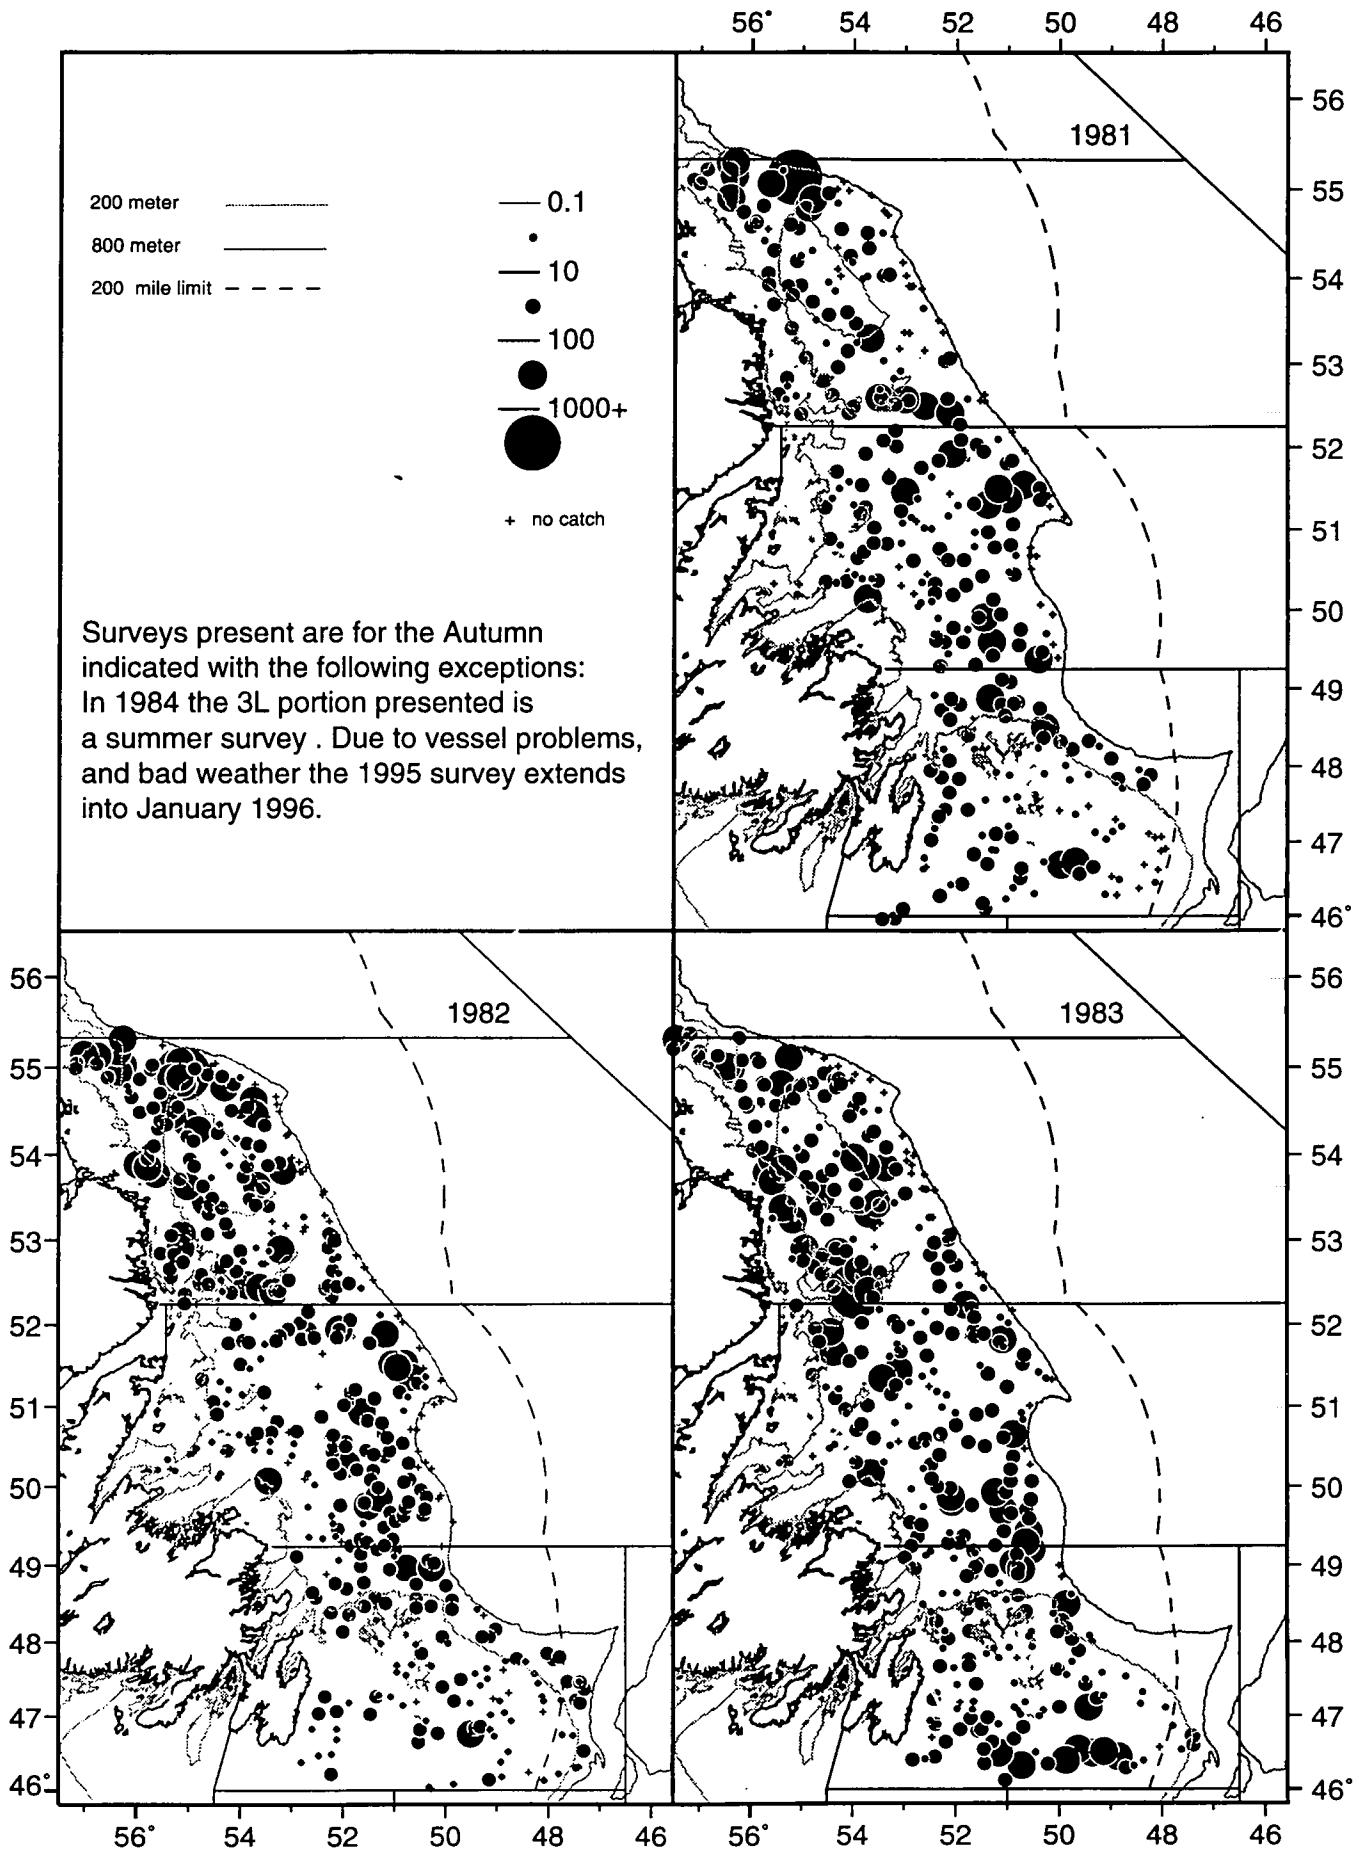

Fig. 13. Cod distribution from autumn RV trawl surveys (numbers per tow).

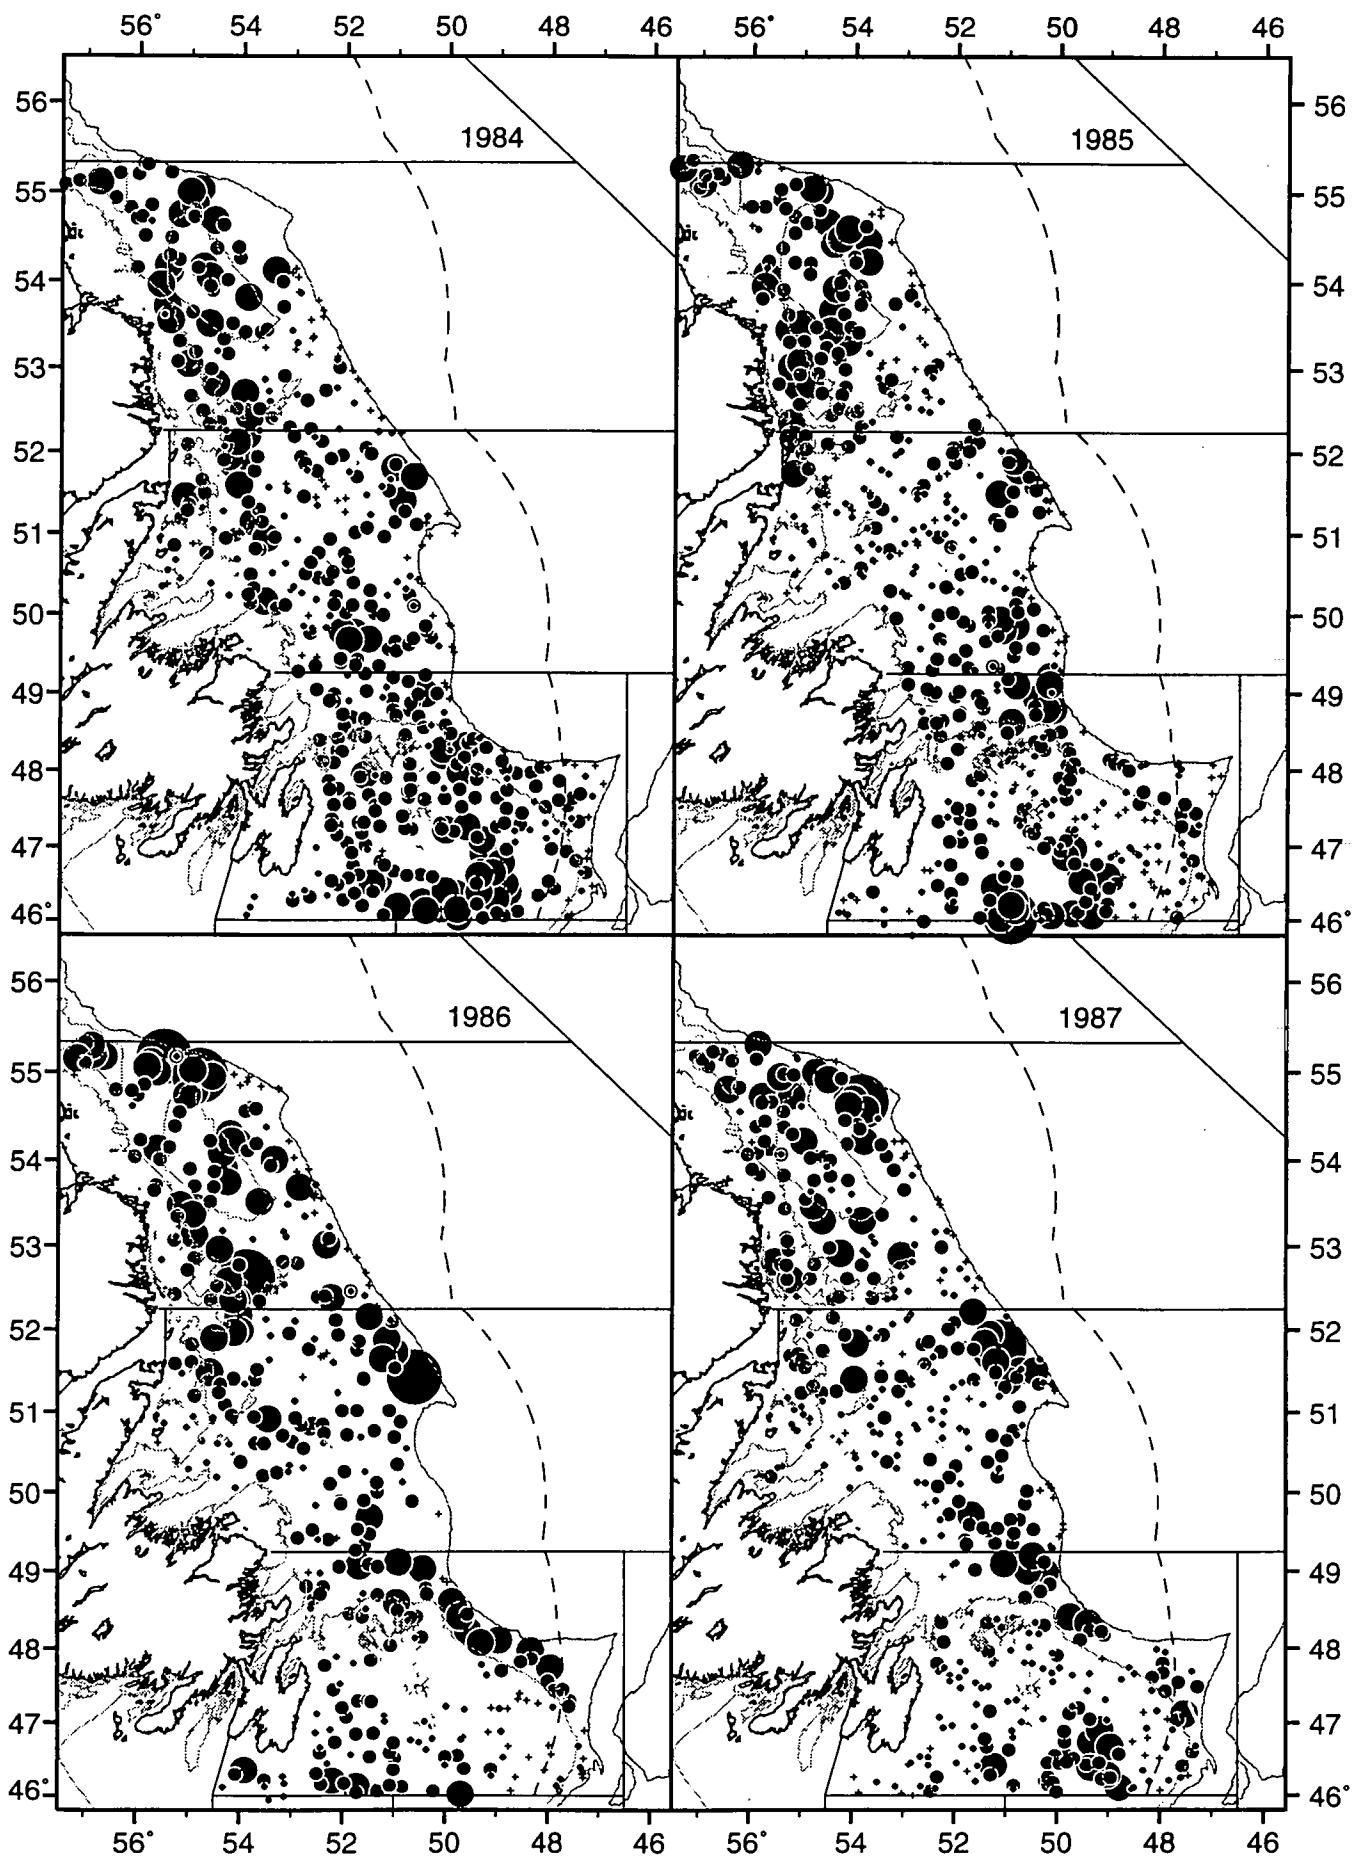

Fig. 13 contd. Cod distribution from autumn RV trawl surveys (numbers per tow).

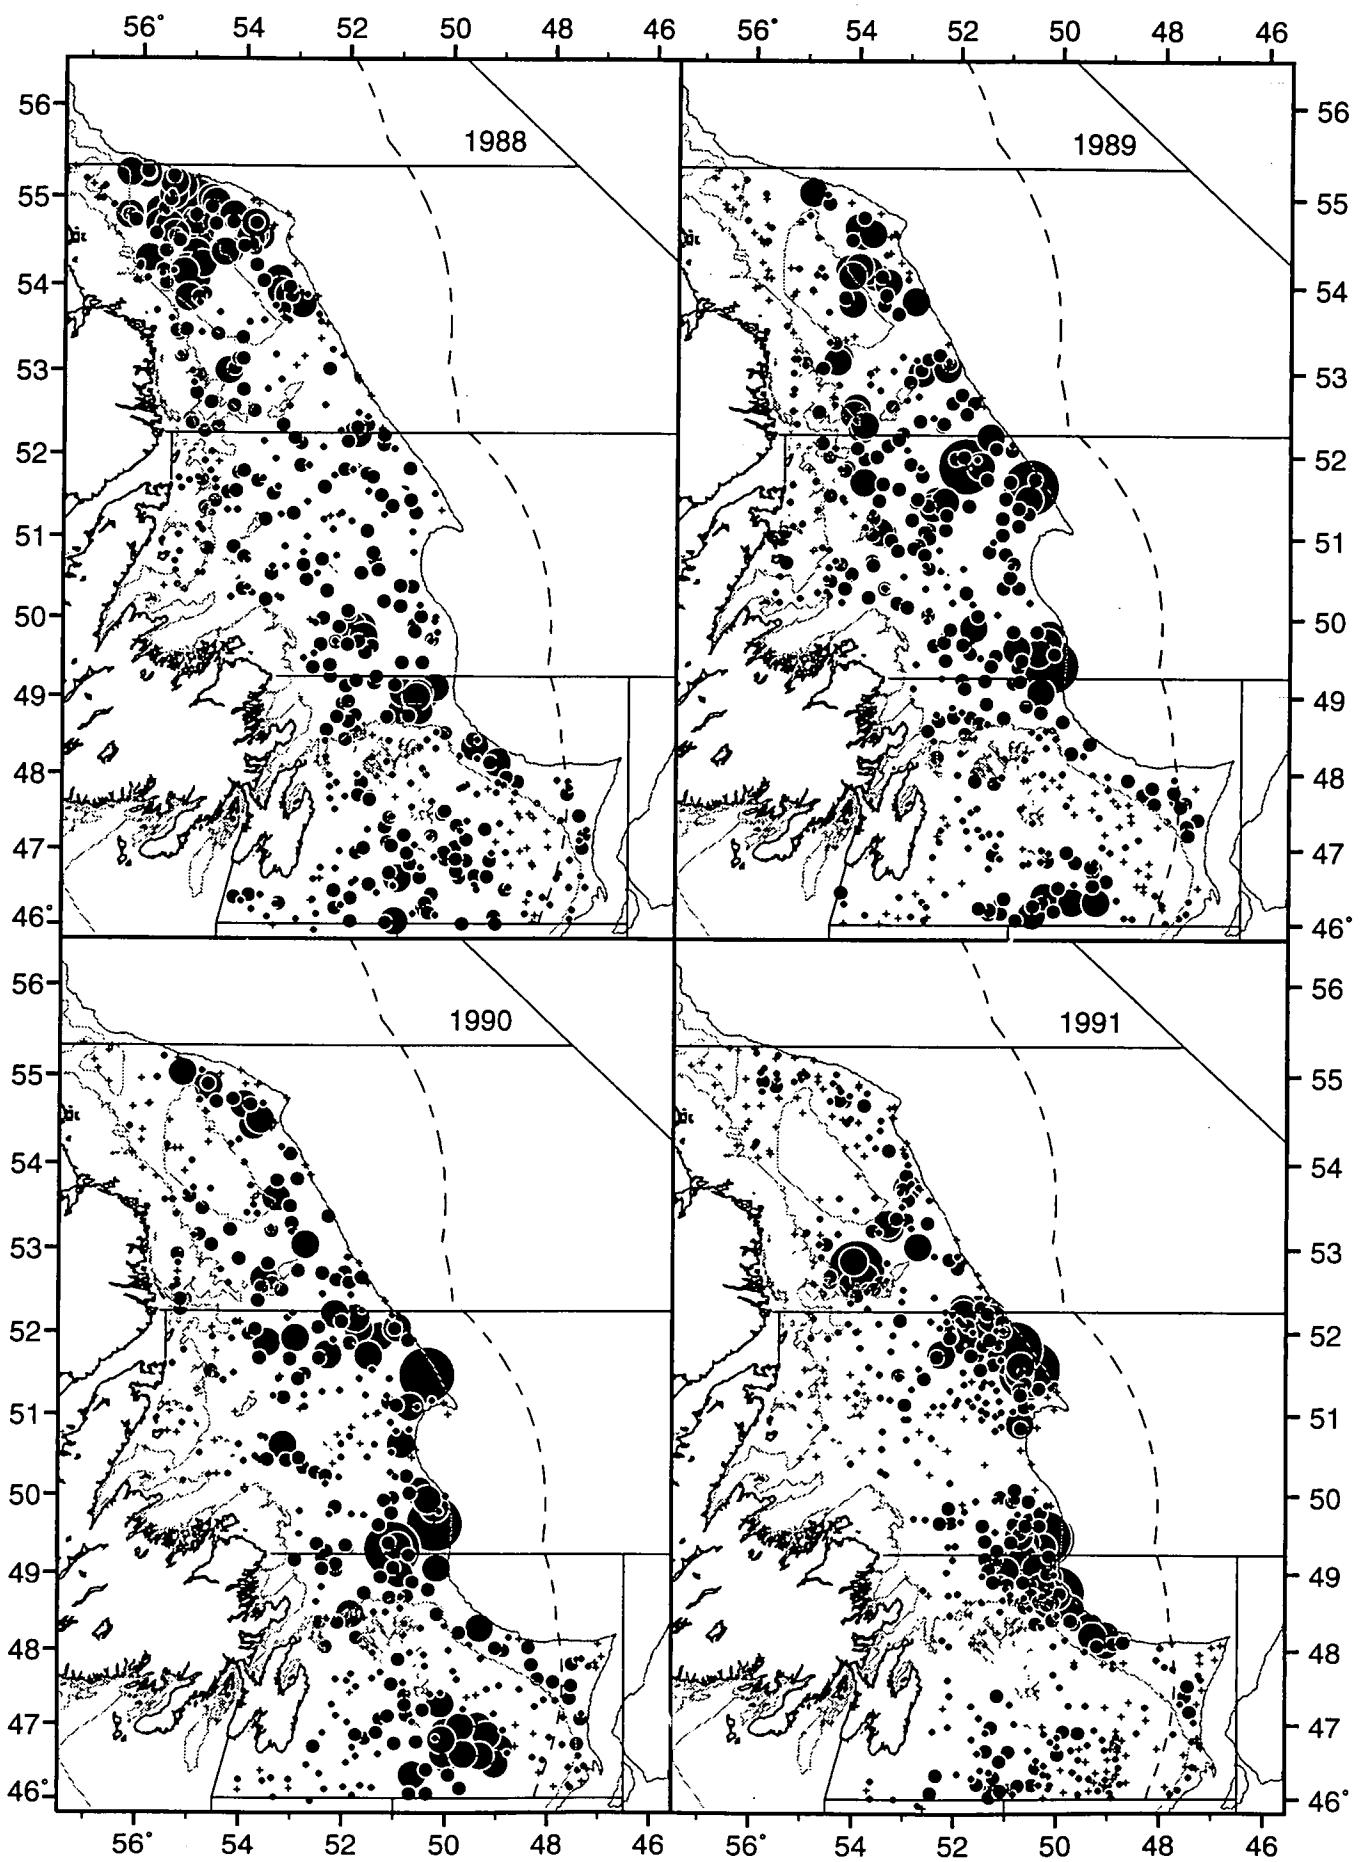

Fig. 13 contd. Cod distribution from autumn RV trawl surveys (numbers per tow).

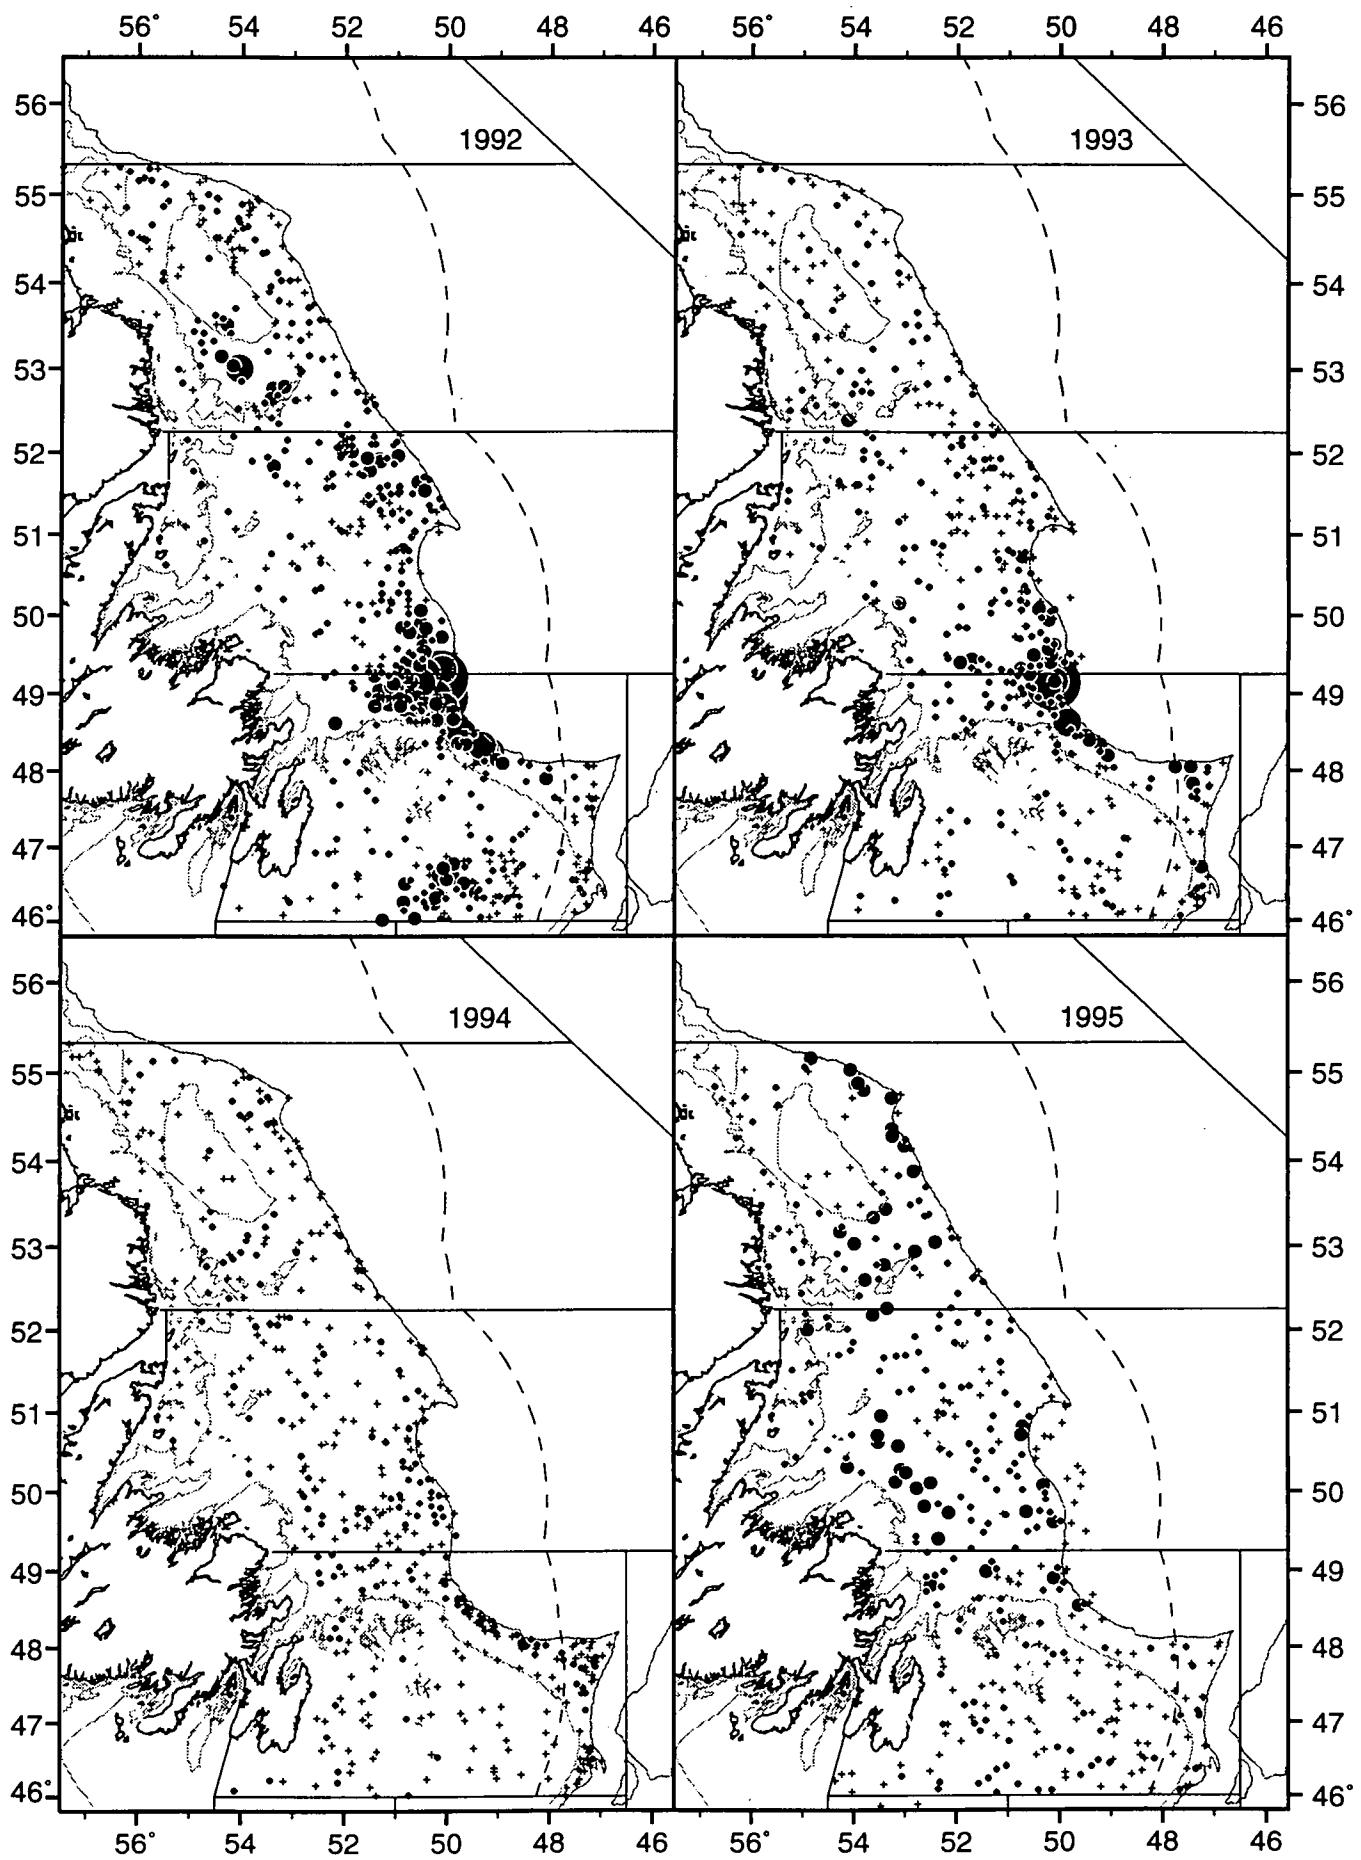

Fig. 13 contd. Cod distribution from autumn RV trawl surveys (numbers per tow).

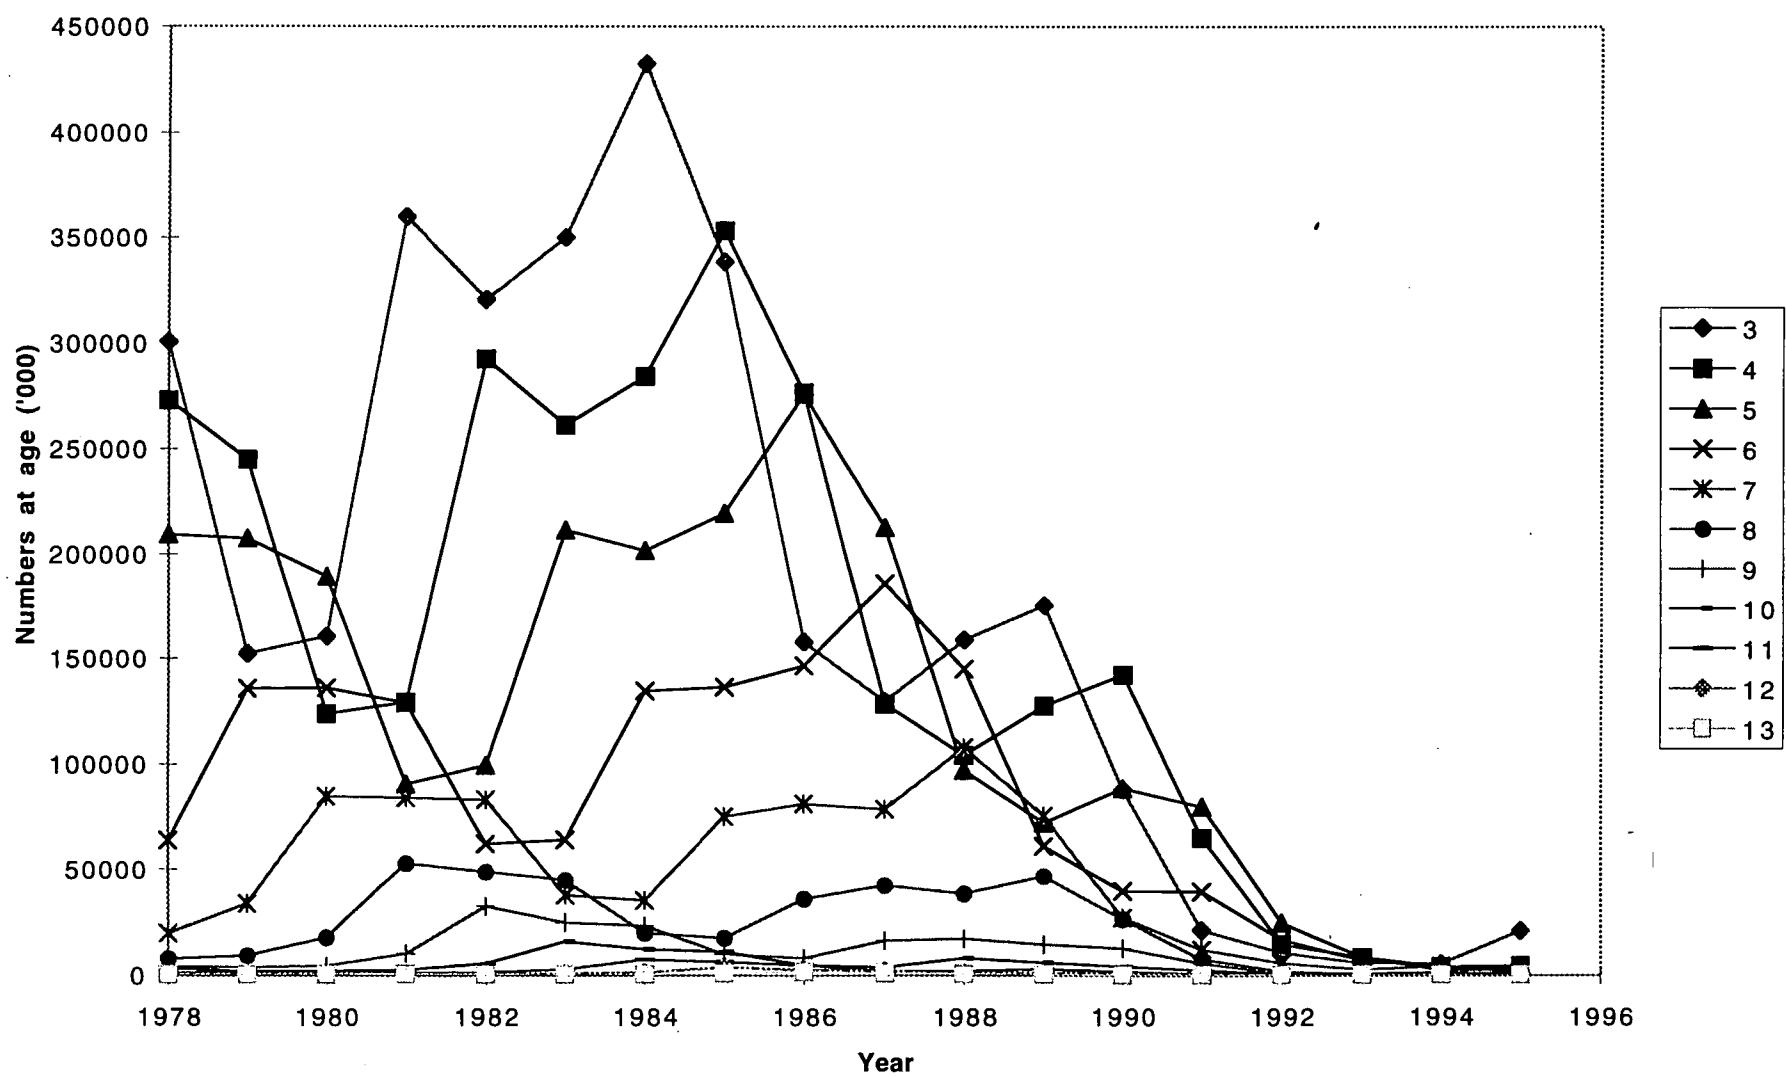

Fig. 14. ADAPT estimates of numbers at age.

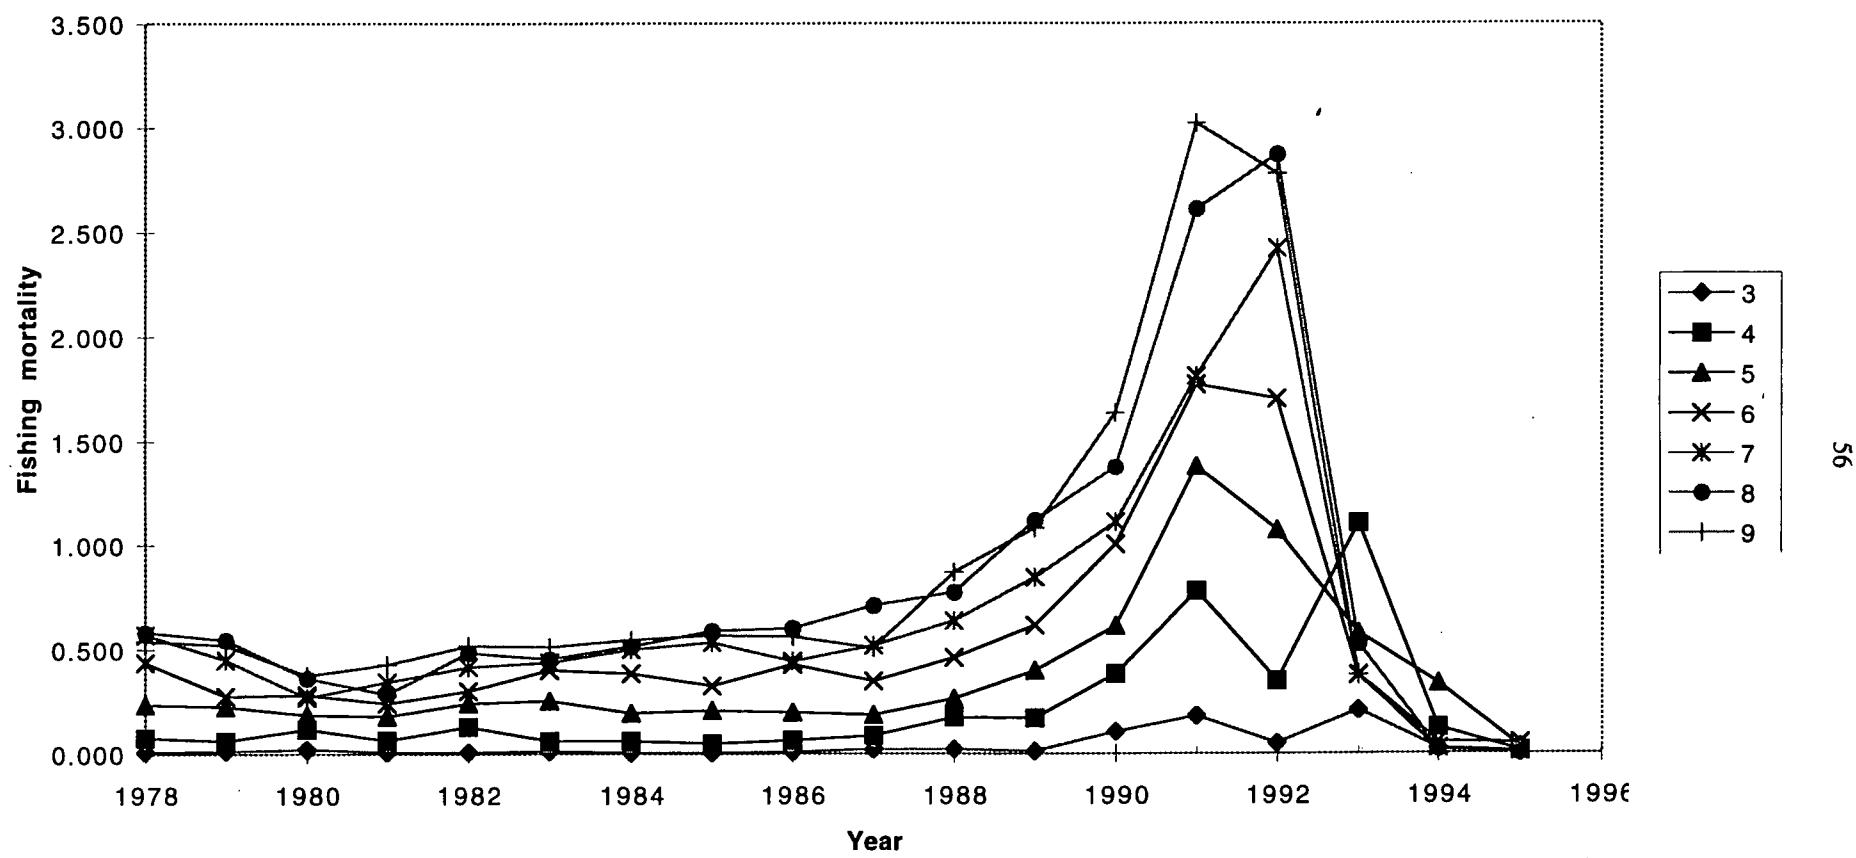

Fig. 15. ADAPT estimates of fishing mortality at age.

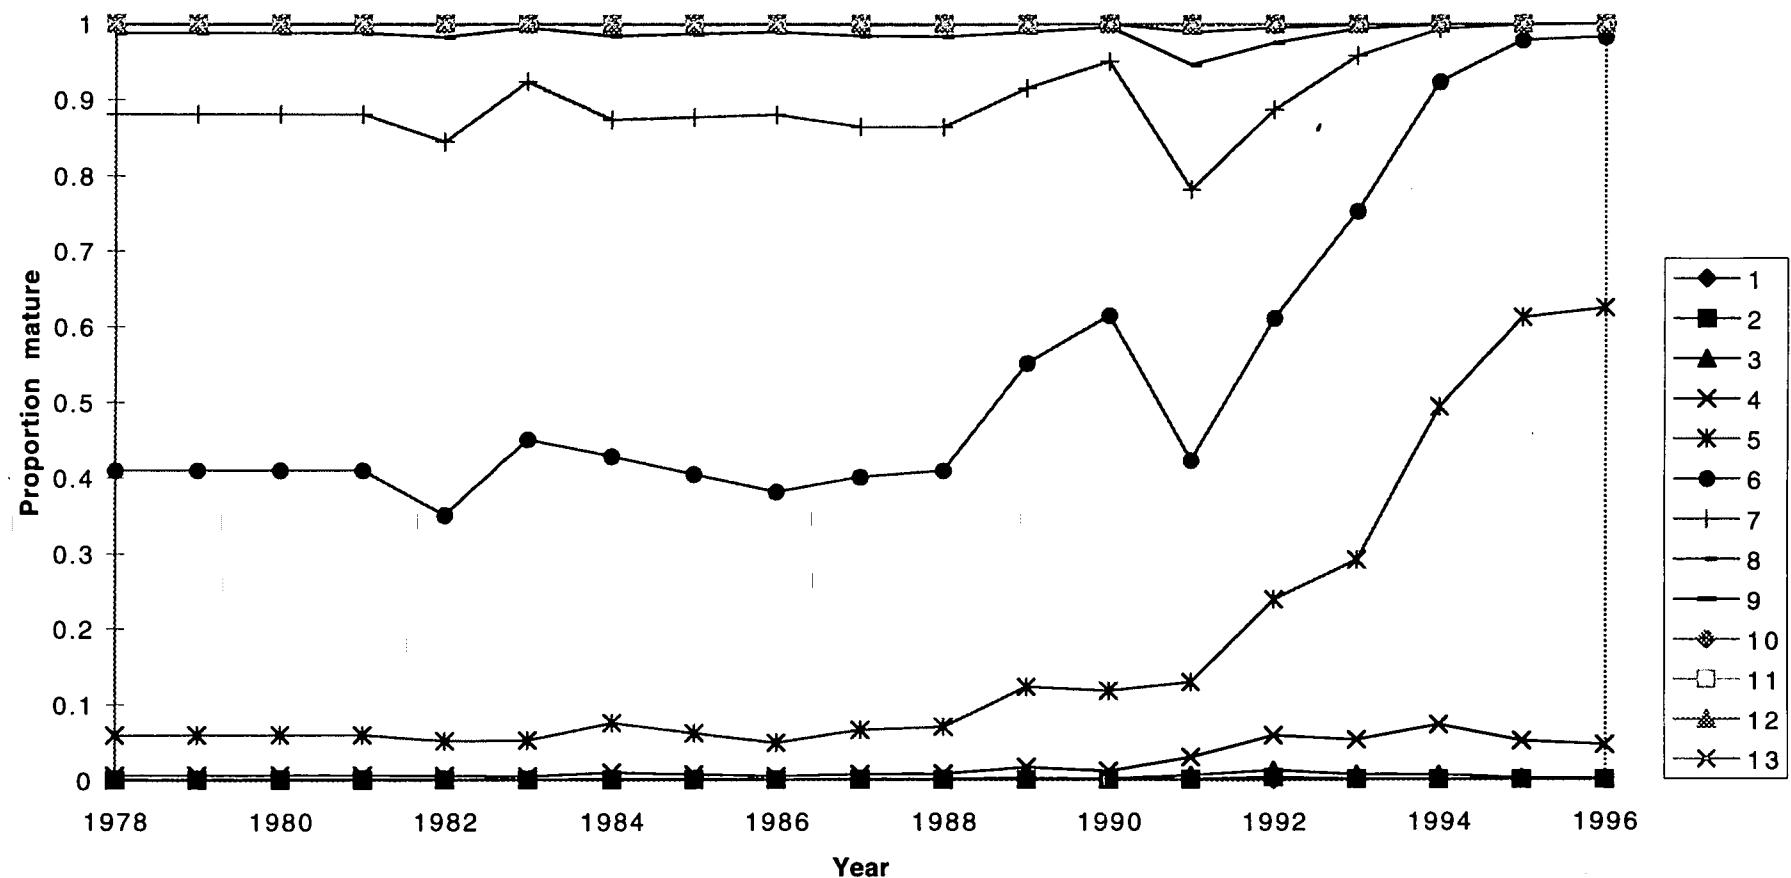

Fig. 16. Estimates of proportion mature at age (from Morgan and Brattey 1996).

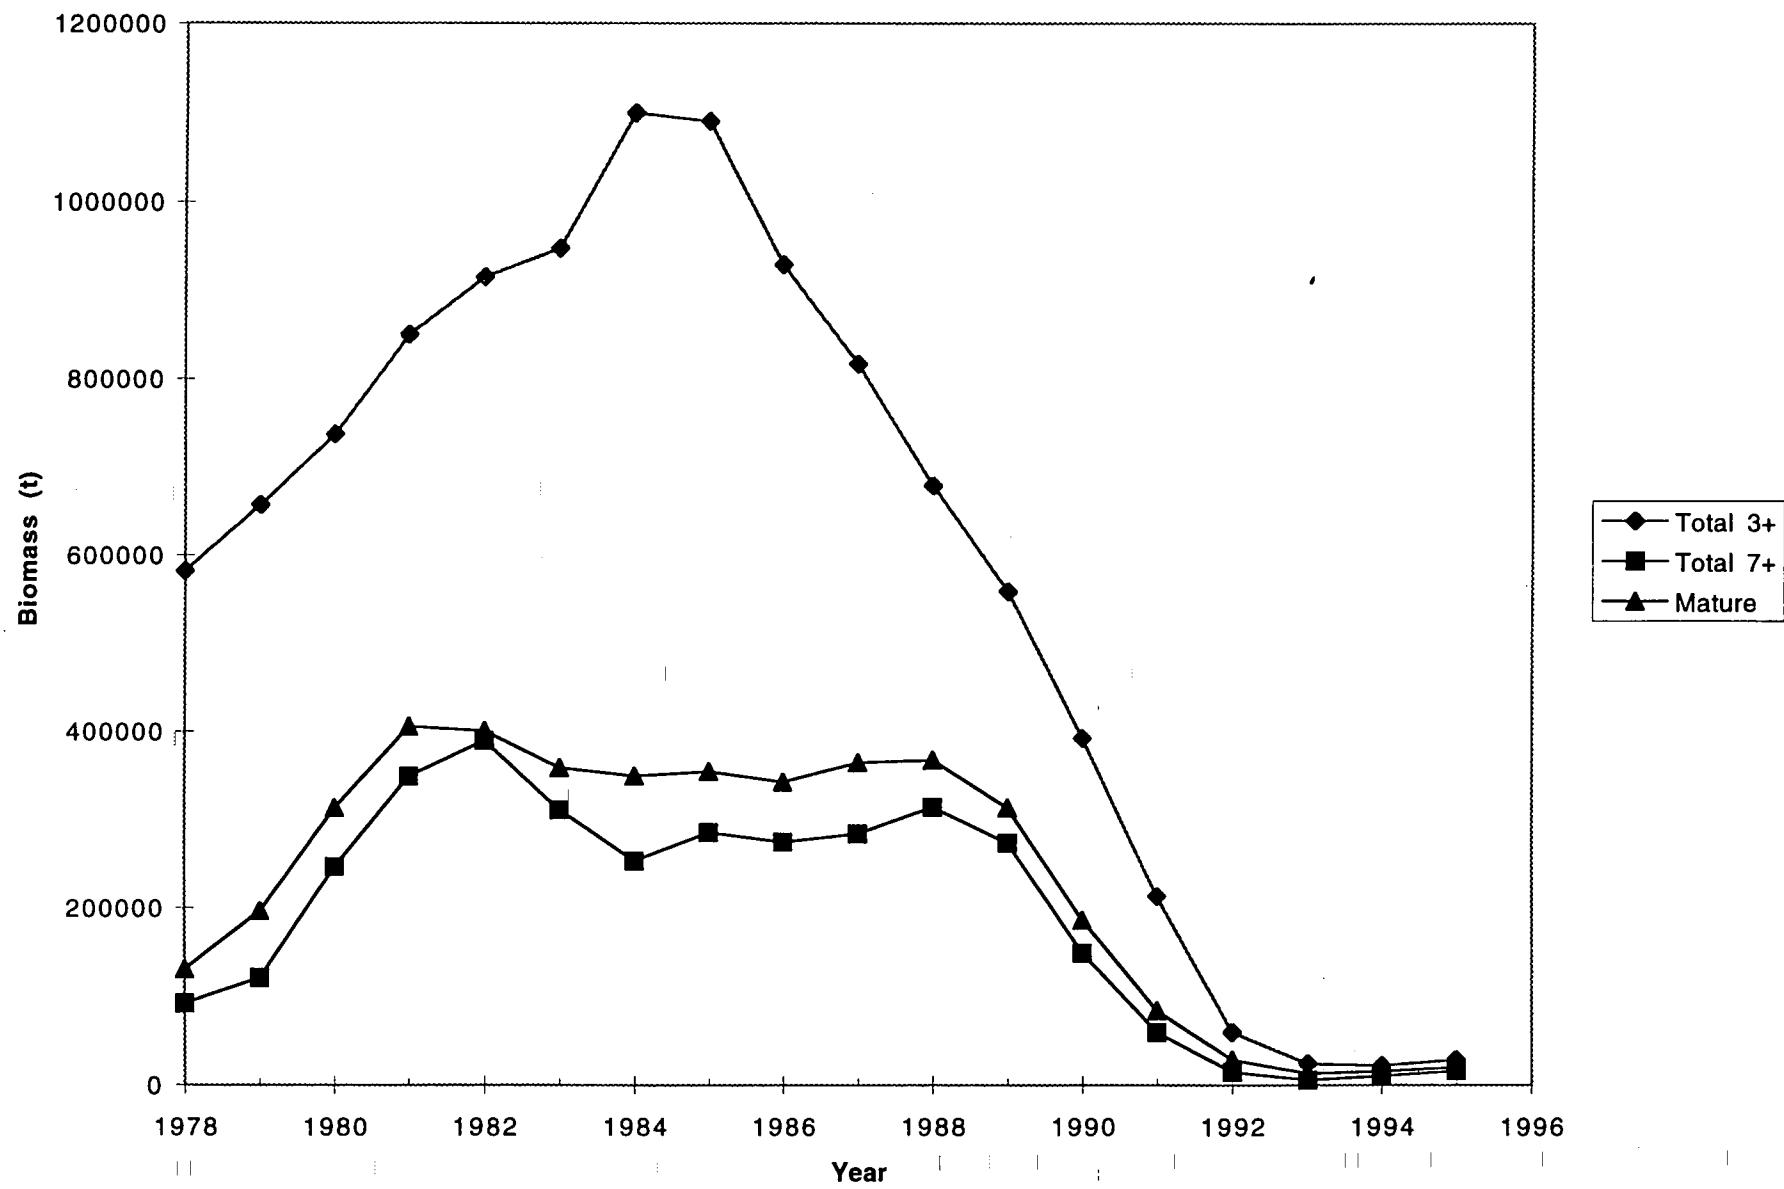

Fig. 17. Estimates of 3+, 7+ and mature biomass from ADAPT and maturity estimates.

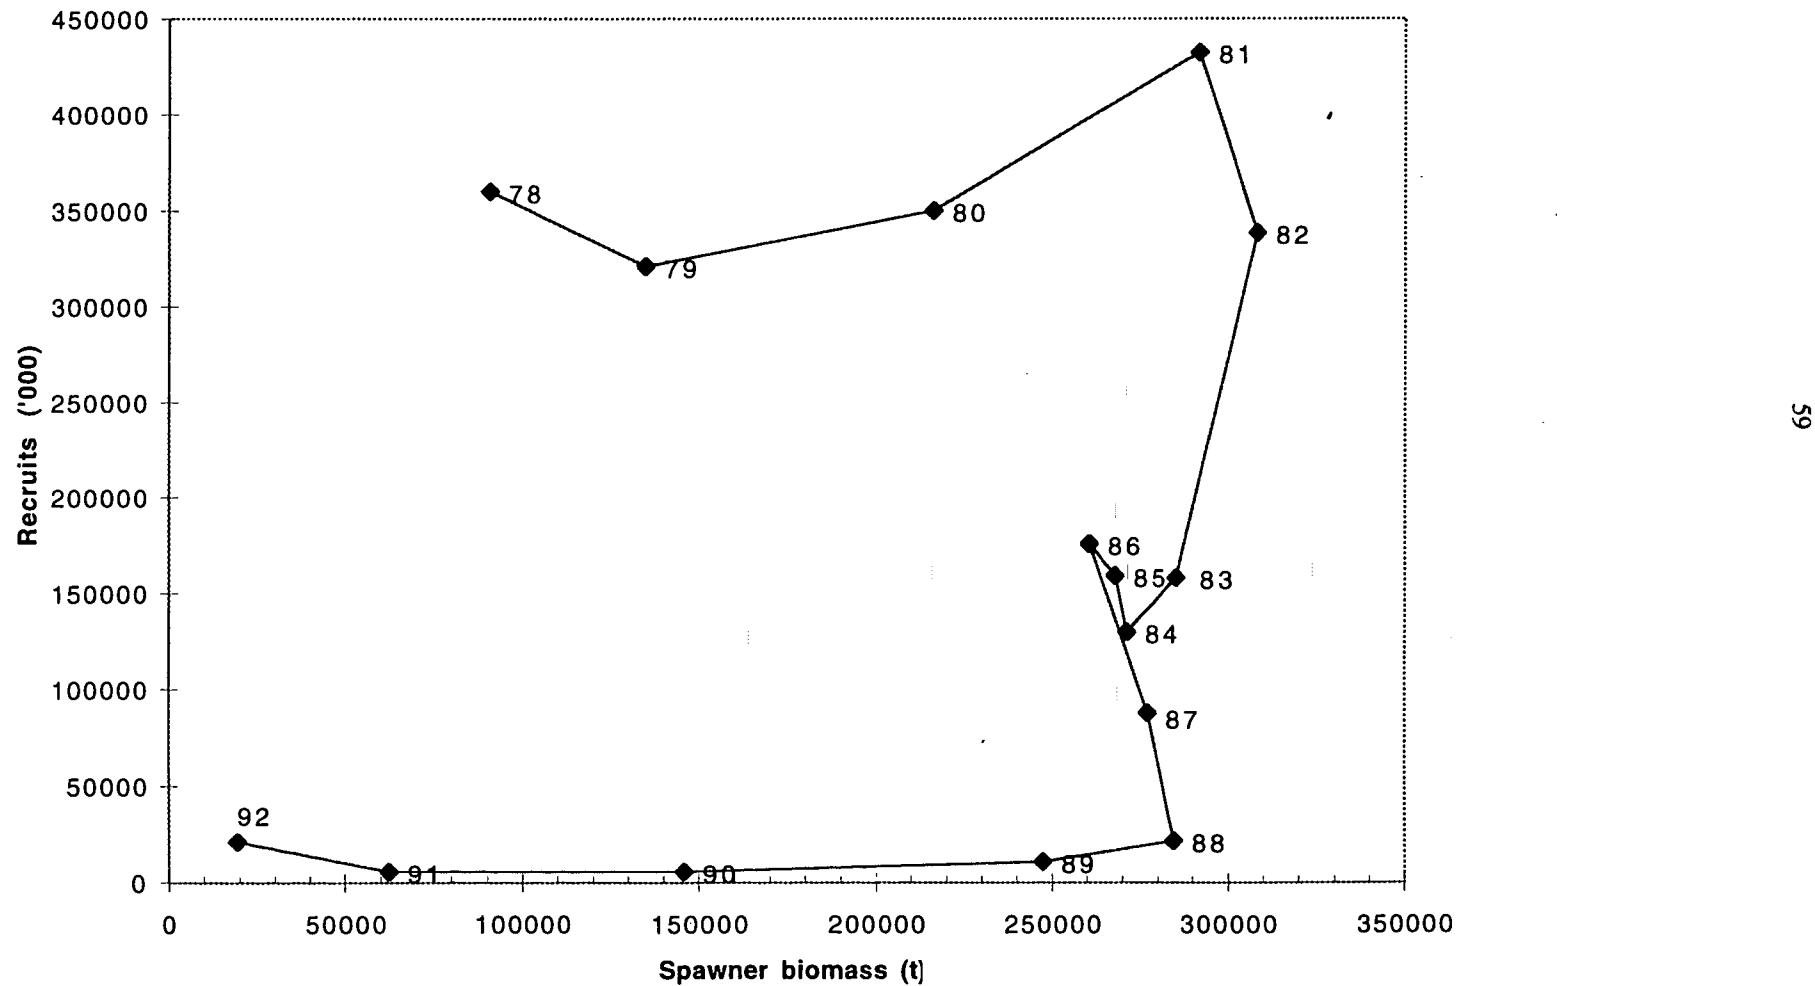

Fig. 18. Phase plot of spawner biomass and recruitment from ADAPT and maturity estimates.

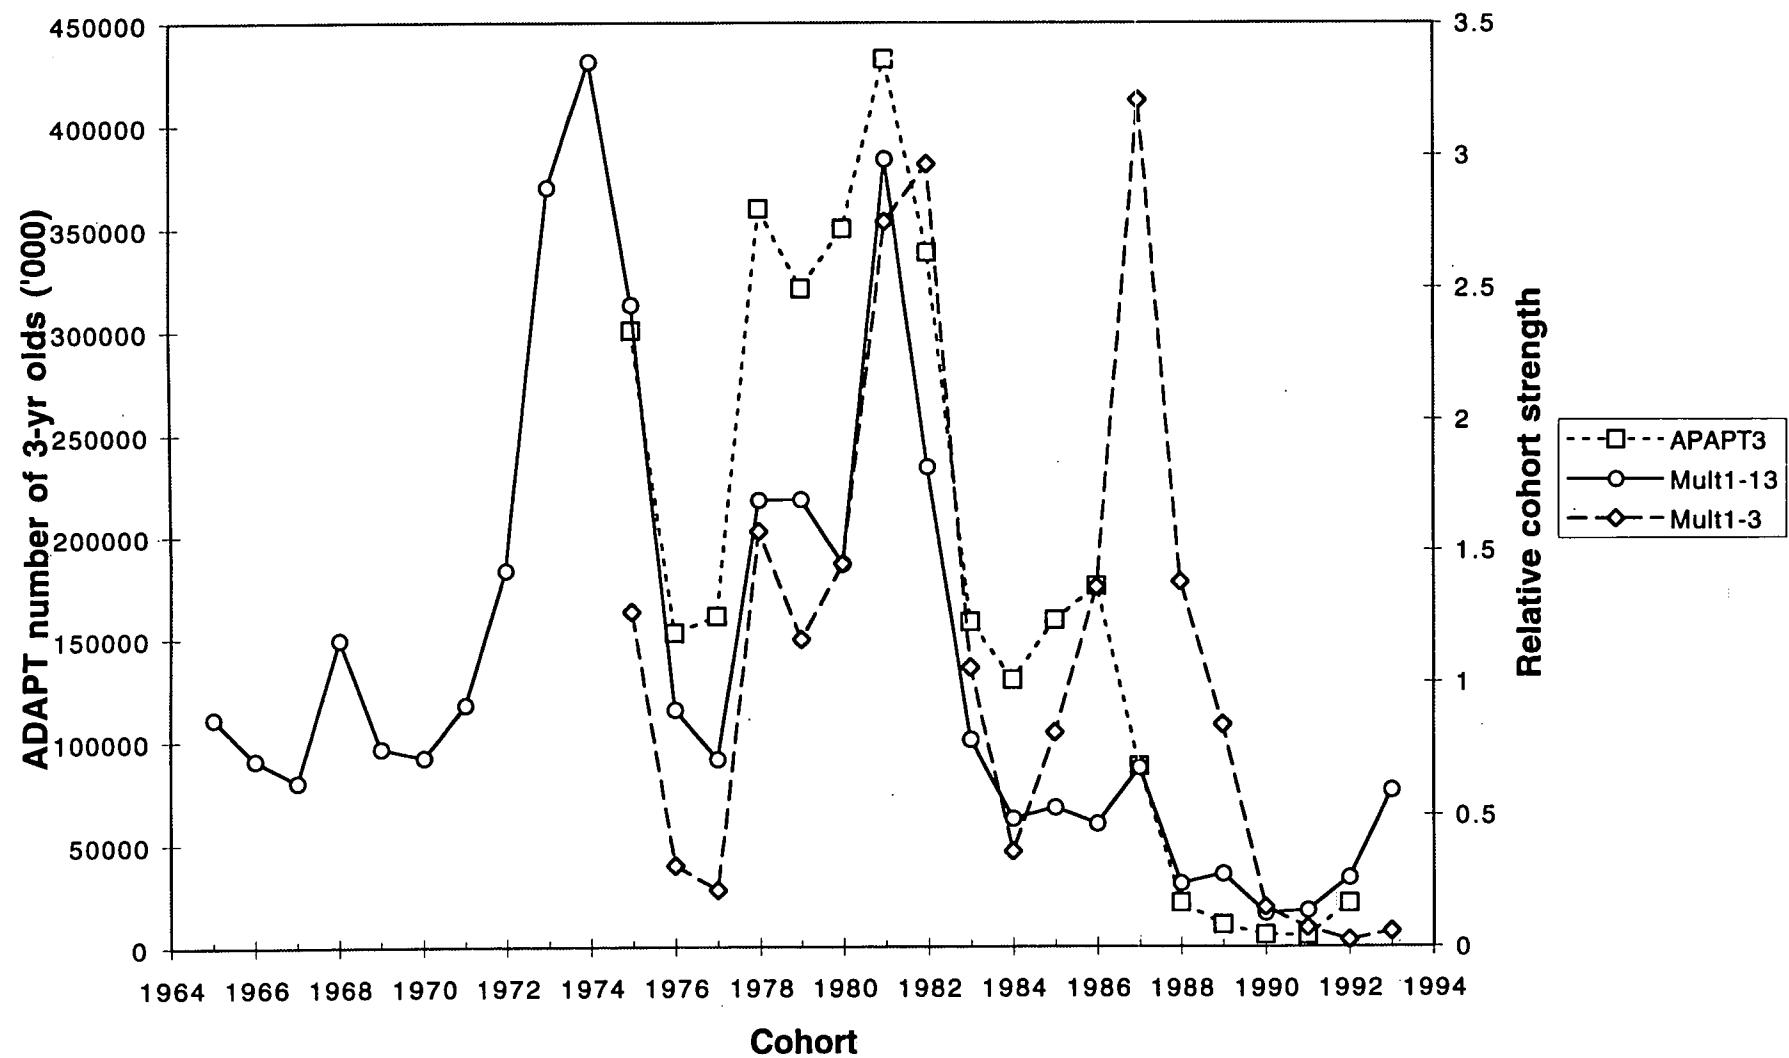

Fig. 19. ADAPT numbers at age 3 and the multiplicative model estimates of relative yearclass strength using data for ages 1-13 and 1-3.

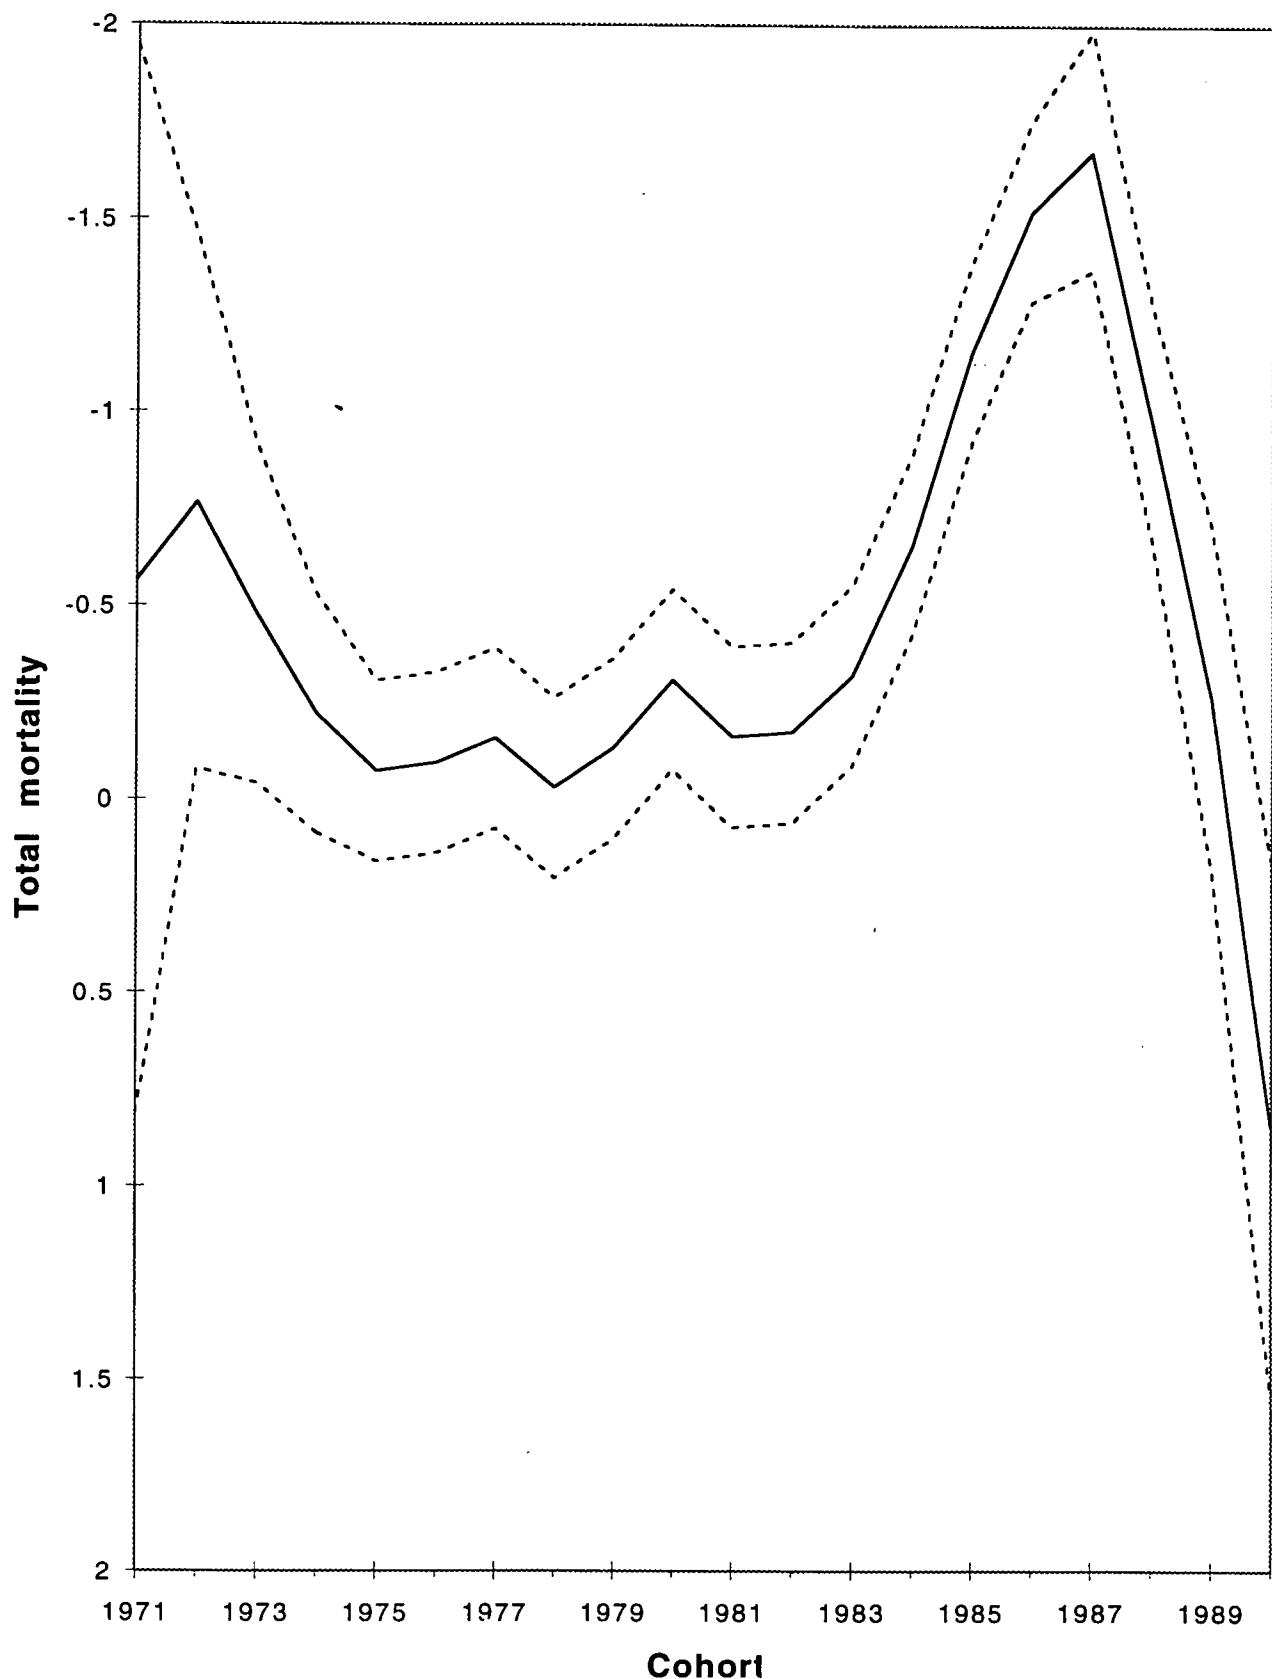

Fig. 20. Estimates of total relative mortality from the fit of a multiplicative model to survey numbers at age for ages 3 to 8. The broken lines indicate plus and minus one standard error.

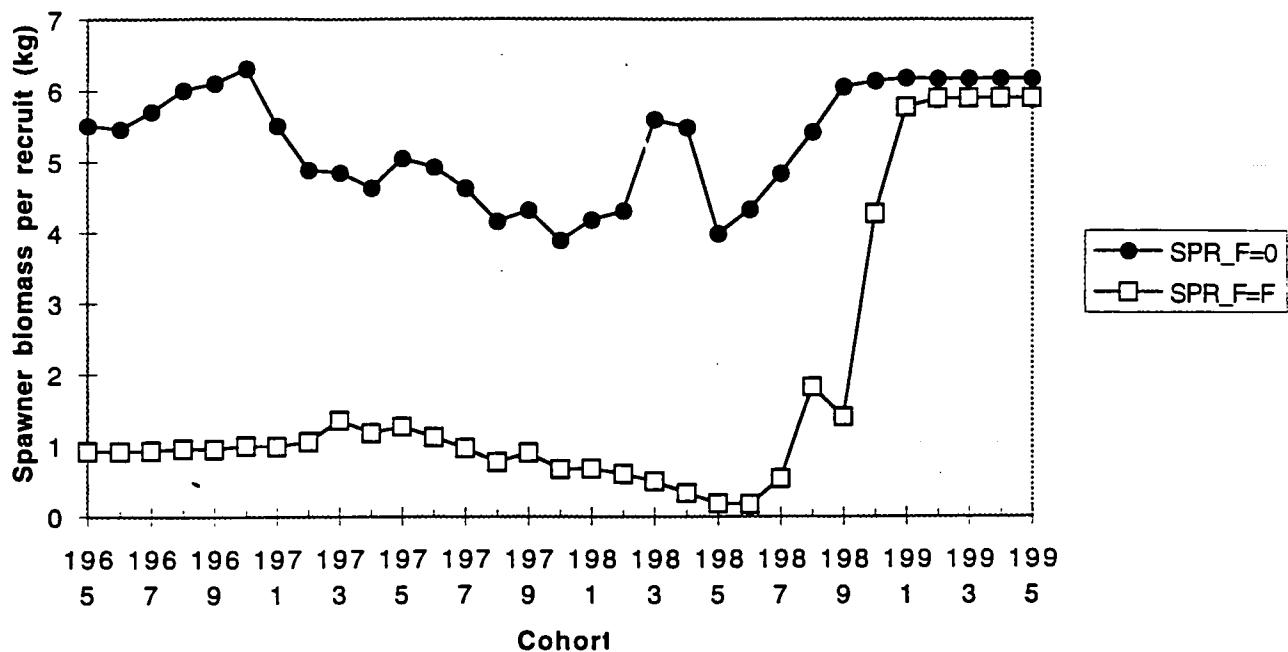

Fig. 21. Estimates of spawner biomass per recruit at zero fishing mortality and at the fishing mortality estimated in the ADAPT.

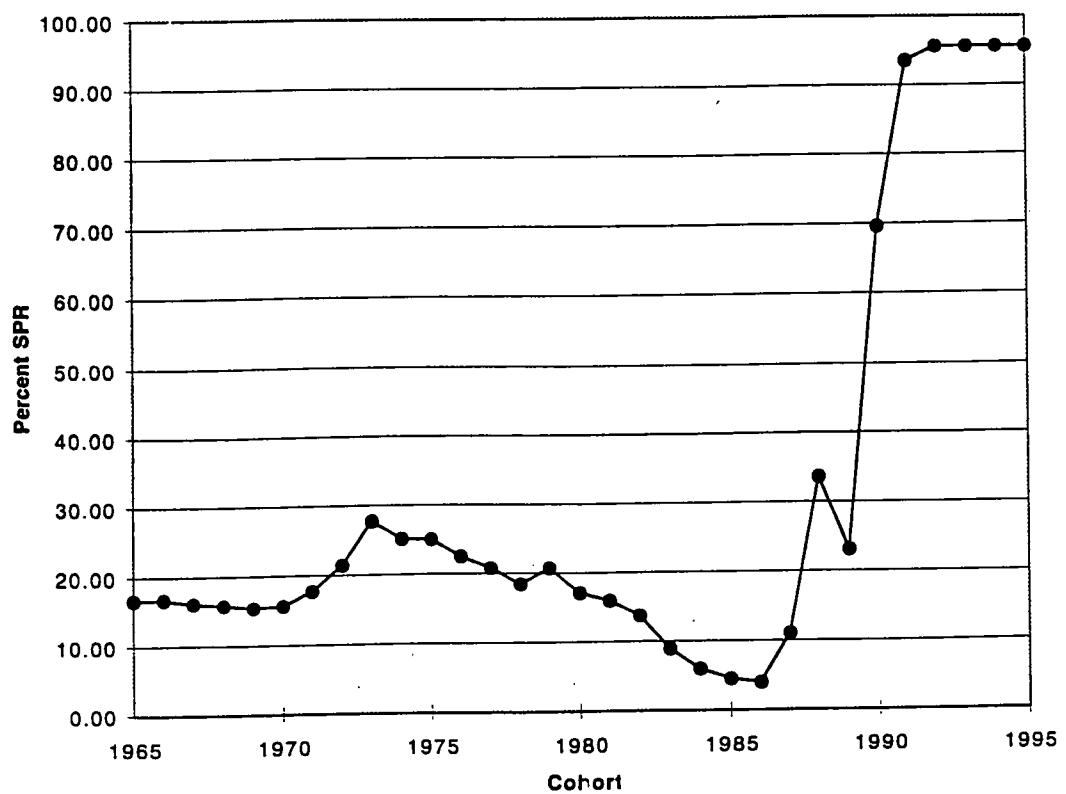

Fig. 22. The percentage of the potential spawner biomass per recruit (i.e. at $F=0$) realized at the prevailing level of fishing mortality. This quantity is termed %SPR.

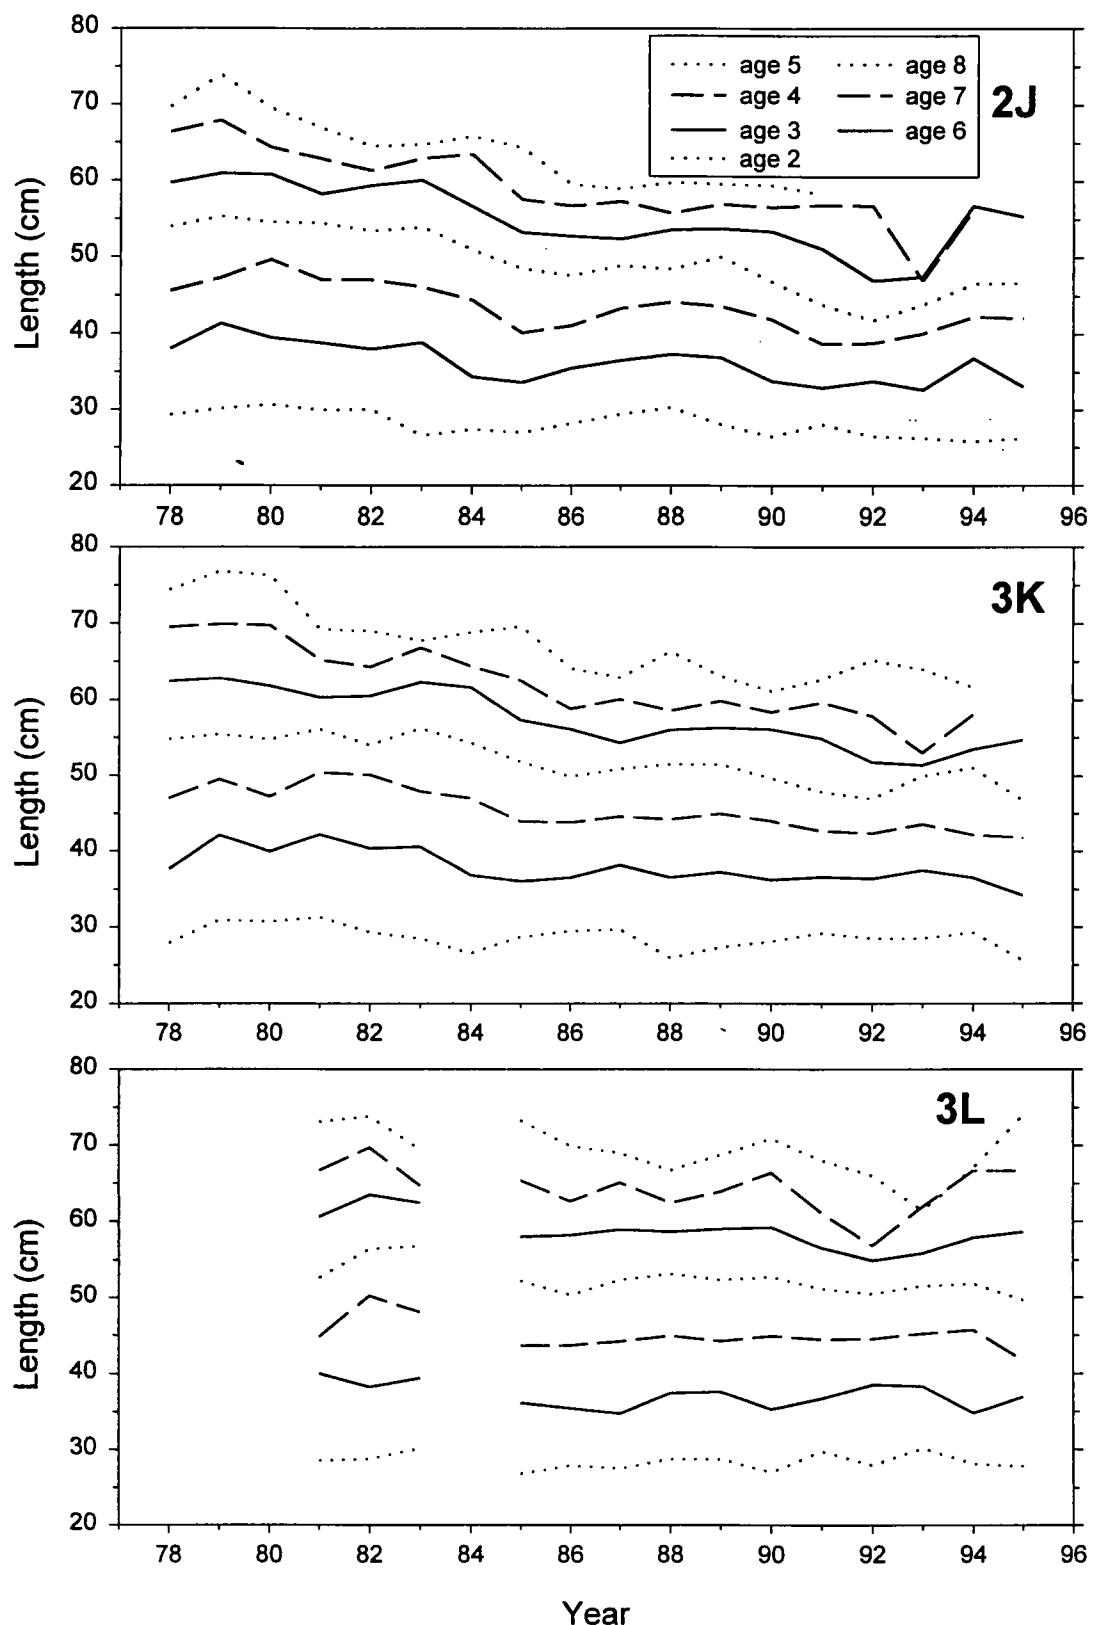

Fig. 23. Mean lengths at age for cod caught during the autumn bottom-trawl surveys. Data from Table 31b.

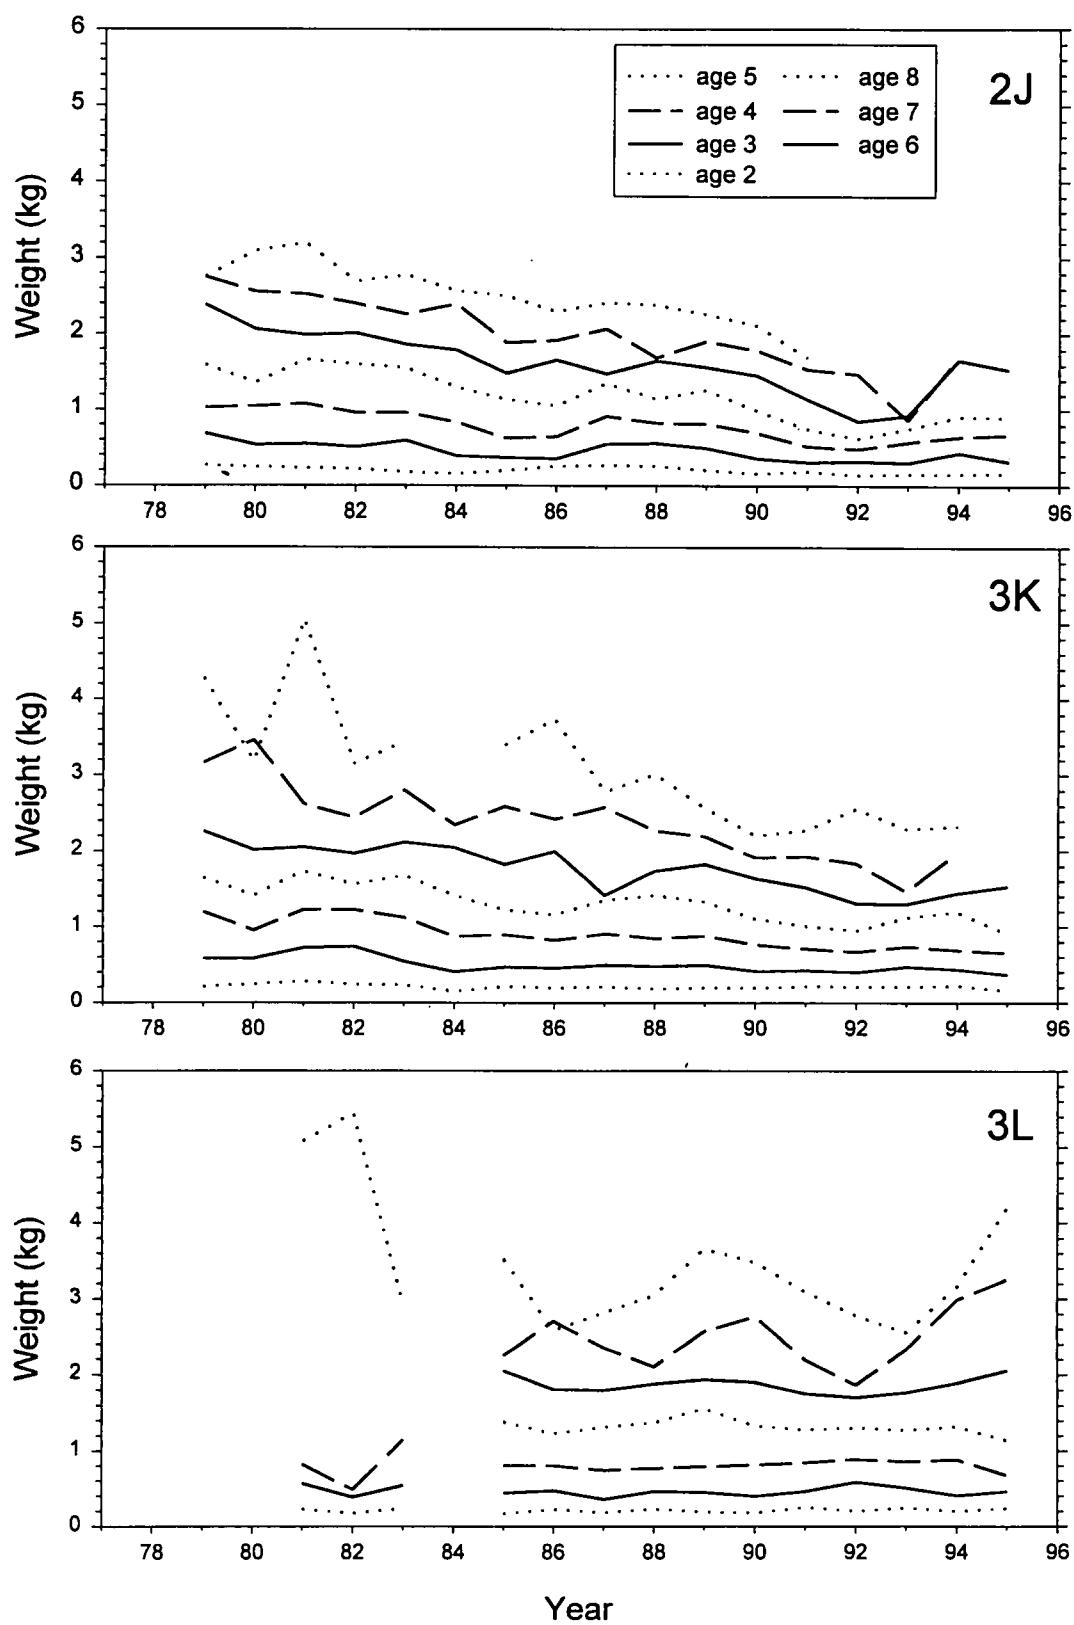

Fig. 24. Mean weights at age for cod caught during the autumn bottom-trawl surveys. Data from Table 32b.

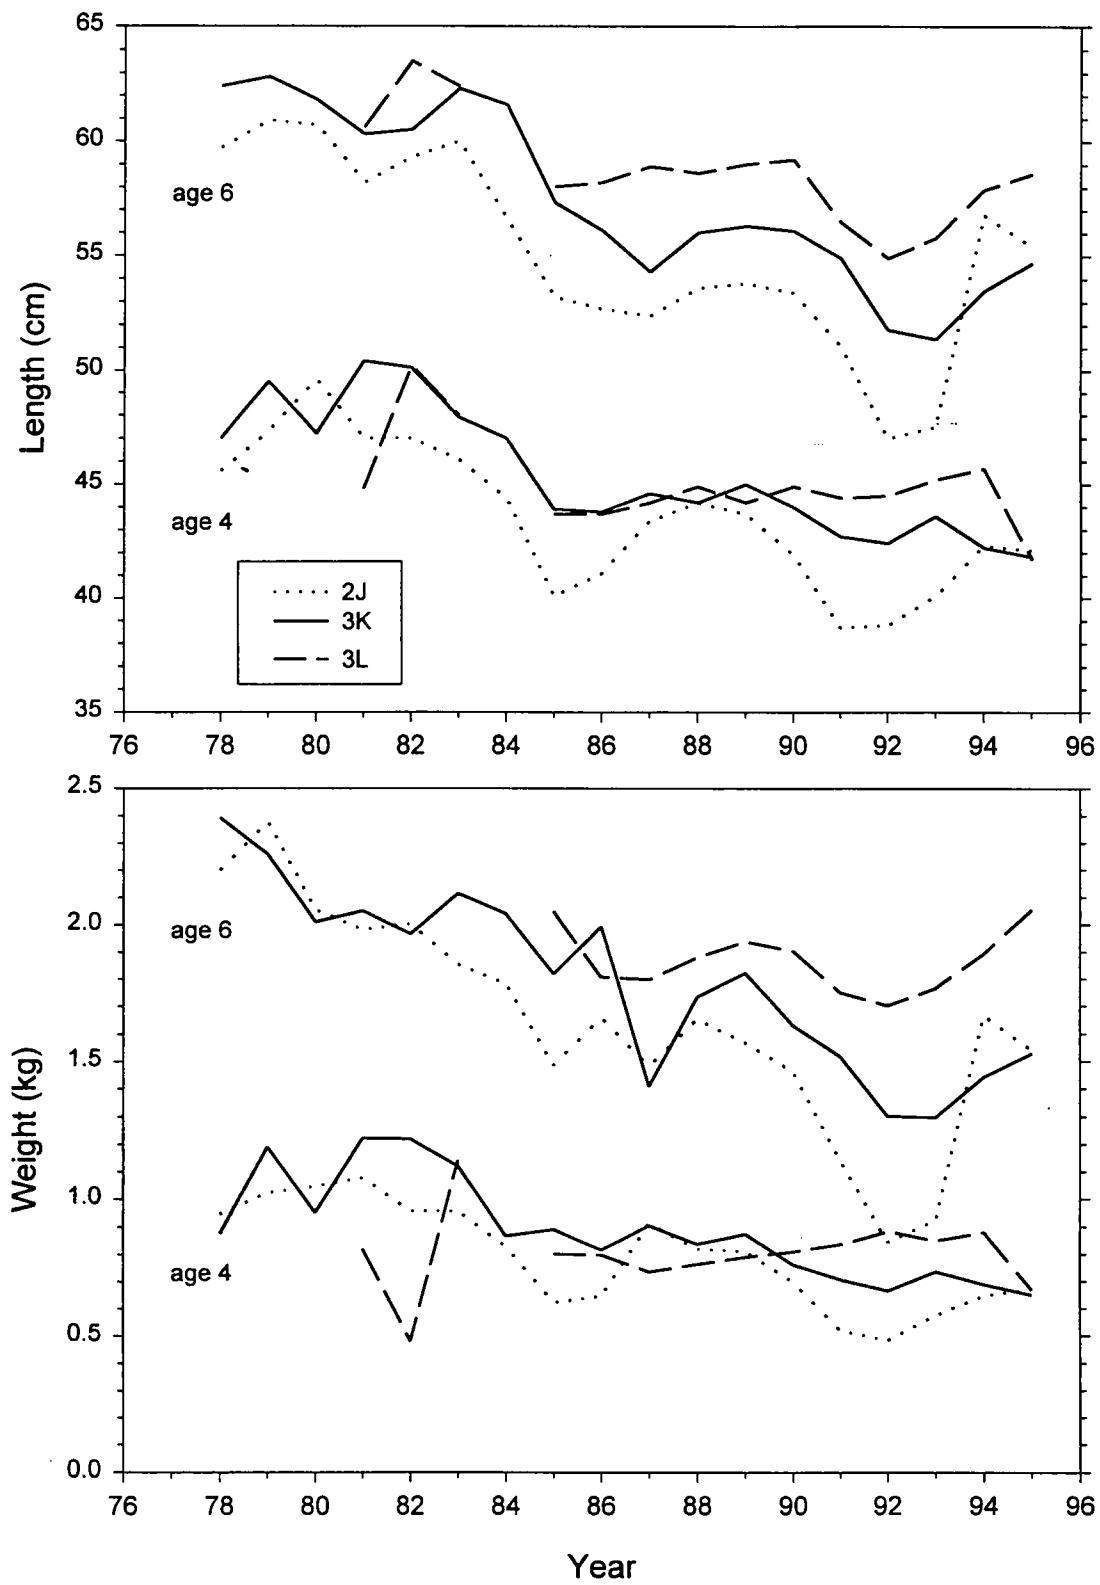

Fig. 25. Mean lengths and weights by Division for cod of ages 4 and 6 caught during the autumn bottom-trawl surveys.
