# Growth and condition of cod in Subdivision 3Ps as determined from trawl surveys (1972-1996) and sentinel surveys (1995) 

by

G.R. Lilly

Science Branch, Department of Fisheries and Oceans PO Box 5667, St John's,Newfoundland Canada, A1C 5X1
${ }^{1}$ This series documents the scientific basis for the evaluation of fisheries resources in Atlantic Canada. As such, it addresses the issues of the day in the time frames required and the documents it contains are not intended as definitive statements on the subjects addressed but rather as progress reports on ongoing investigations.

Research documents are produced in the official language in which they are provided to the secretariat.
${ }^{1}$ La présente série documente les bases scientifiques des évaluations des ressources halieutiques sur la côte atlantique du Canada. Elle traite des problémes courants selon les échéanciers dictés. Les documents qu'elle contient ne doivent pas étre considérés comme des énoncés définitifs sur les sujets traités, mais plutôt comme des rapports d'étape sur les études en cours.

Les Documents de recherche sont publiés dans la langue officielle utilisé dans le manuscrit envoyé au secrétariat.

#### Abstract

The growth and condition of cod in Subdivision 3Ps were monitored by sampling catches during winter-spring research bottom-trawl surveys in the offshore in 1972-1996 and sentinel surveys in the inshore in 1995. In the offshore, length-at-age peaked in the mid to late 1970s and varied with no trend (younger ages) or declined slightly (older ages) during the past decade. Condition, as measured by both gutted body weight and liver weight relative to length, was low in fish sampled during the 1993-1996 surveys. However, it is not clear that the values were below normal, because the 1993-1996 surveys were conducted in April when condition is near the low point of the seasonal cycle, and only one of the earlier surveys was conducted at about the same time. The condition of fish sampled from the sentinel surveys varied seasonally and spatially. The quantity of food in stomachs of cod sampled during the sentinel surveys was generally low. A dramatic increase in stomach fullness occurred in July when the cod fed on capelin. Liver index reached a peak at that time.

## Résumé

Il a été procédé à un contrôle de la croissance et de la condition des morues de la sous-division 3Ps par échantillonnage des captures des relevés de recherche bauturiers au chalut de fond d'hiver et de printemps de la période 1972-1996 et de celles des pêches sentinelles côtières de 1995. Dans la zone hauturière, le paramètre de la longueur selon l'âge a atteint un maximum du milieu à la fin des années 1970 et a ensuite varié sans présenter de tendance (classes plus jeunes) ou a légèrement diminué condition (classes plus âgées) au cours de la dernière décennie. Le facteur de condition, déterminé à partir du poids après éviscération et du poids du foie en fonction de la longueur, était faible chez les poissons des relevés de 1993-1996. In n'est cependant pas certain que ces valeurs soient inférieures à la normale car les relevés de cette période ont été réalisés en avril, au moment où le facteur de condition est au plus bas de son cycle saisonnier, et seulement un des relevés antérieures avait été effectué à une période semblable. Le facteur de condition des poissons des relevés sentinclles était généralement faible. Une augmentation extrêmement importante de ce contenu a été notée en juillet, lorsque les morues se nourrissent de capelans. L'indice basé sur le poids du foie a aussi présenté un pic à ce moment.

## Introduction

Cod (Gadus morhua) in several areas of Atlantic Canada experienced pronounced declines in growth and condition during the late 1980s and early 1990s. The extent to which similar changes were experienced by cod off the south coast of Newfoundland (Subdivision 3Ps) has not been determined, even though sampling for length-at-age has been conducted during research bottom-trawl surveys since 1972 and sampling of weight-at-length and weight of individual body parts has been conducted since 1978. The first purpose of this paper is to describe the sampling which has been conducted during winter-spring assessment surveys, and to present summary information on annual changes in length-at-age, weight-at-age, weight-at-length (condition) and weight of liver.

The second purpose is to describe the sampling conducted during the sentinel surveys in the inshore regions of Subdivision 3Ps in 1995, and to report temporal and spatial variability in condition, liver index and stomach contents.

## Materials and Methods

## Research vessel surveys

## Survey design

Cod were caught during stratified-random bottom-trawl surveys conducted in Subdivision 3Ps during winter-spring 1972-1996. The timing of the surveys varied considerably, with the earliest and latest dates of fishing being January 27 in 1988 and June 12 in 1975 (Table 1). The median dates of fishing varied from February 7 to June 6 . The number of fishing stations also varied considerably, from a low of 44 in 1978 to a high of 166 in 1994. The number of stations tended to be lower in the 1970s and early 1980s. Note that there were two surveys in 1993; one in February and one in April. Only the latter has been included in the time-series.

The survey gear was changed twice during the period 1972-1996. The 51 m side trawler R.V. 'A. T. Cameron' (1972-1982) deployed a Yankee 41-5 trawl, the sister 50 m stern trawlers R.V. 'Alfred Needler' $(1983,1984)$ and R.V. 'Wilfred Templeman' $(1985-1995)$ deployed an Engel-145 high-lift trawl, and in 1996 the R.V. 'Wilfred Templeman' deployed a Campelen trawl with rockhopper foot gear. In all instances, a 29 mm mesh liner was inserted in the codend. In 1972-1995, tows were made at 3.5 knots for 30 min at each fishing station, whereas in 1996 tows were made at 3.0 knots for 15 min . Catches from the few stations of non-standard duration were appropriately adjusted. Fishing in all years was conducted on a $24-\mathrm{h}$ basis.

Fishing stations were allocated randomly within depth strata, with a new station selection being conducted each year. The number of stations allocated to each stratum was roughly proportional to the size of the stratum, with the constraint that each stratum be allocated no fewer than 2 stations. (There were instances in which the sampling objectives were not realized.)

Doubleday (1981) provides illustrations of the strata and information on their areas and depth-ranges. Several additions and modifications to the stratification scheme are described by Bishop (1994) and Murphy (1996).

## Biological sampling

Sampling of cod for otoliths and various biological attributes was conducted using two distinct procedures (Table 2). The first involved determination of biological attributes (eg. fork length, cm ) and the extraction of otoliths at sea. The second, which was started in 1978, involved the determination of body length at sea followed by the freezing of the fish for detailed examination in the laboratory at the Northwest Atlantic Fisheries Centre, St. John's. These frozen fish were thawed in fresh water and weighed (to the nearest 10 g ) before being cut (round weight) and again after removal of the organs from the abdominal cavity (gutted weight). The liver and gonad were also weighed (g) or measured volumetrically (ml).

For each of these two methods of sampling, there were several changes in what constituted a sample and several changes in the biological attributes measured. With respect to the sampling of unfrozen fish, a single sample was obtained for the whole Subdivision during 1972-1984, two samples were obtained during 1985-1987, and a single sample was obtained in 1988-1996. With respect to the sampling of frozen fish, a single sample was obtained for the whole Subdivision during 1978-1984, two samples during 1985-1988, three samples during 1989-1993 (February), four samples in 1993 (April) and five samples in 1994-1996. The boundaries of the sample areas varied over time, and in some years (notably 1985-1988) several strata were not included in any of the samples.

For the period 1978-1984, all information regarding body weight or the size of individual body parts came only from the frozen fish. Additional information was collected at sea starting in 1985. From 1985-1989, the volumes of the liver and gonad were determined with volumetric cylinders for all fish sampled at sea. In 1990, balances for weighing at sea were first used to obtain round weight, gutted weight, and weights of large livers and gonads for all fish sampled at sea. The sizes of small ( $<100 \mathrm{~g}$ ) livers and gonads continued to be determined volumetrically. In 1991 and subsequent years, weights were obtained for livers and gonads of all sizes. An important change for the frozen fish, initiated in 1991, was the determination of round weight at sea prior to freezing.

The number of aged fish for which body length, body weight and liver size (weight or volume) were determined in each year is given in Table 3. The number of aged fish for which length and round weight were determined are given for each year and age in Tables 4 and 5 respectively.

Data analysis
Mean lengths at age were calculated by weighting individual measurements in the biological sample by the ratio of the population number per 3 cm length class to the number of fish sampled in the same length class, where the population number was calculated by areal
expansion of the stratified mean catch at length per tow (Smith and Somerton 1981). Mean weights at age were calculated by weighting each individual fish weight by the ratio of the population number per 3 cm length class to the number of fish sampled in the same length class. Note that weights were not obtained in 1972-1977 and that in 1978-1989 the number of fish for which weights were recorded is smaller than the number measured.

The condition of each fish was expressed using Fulton's condition factor $\left(\left(\mathrm{W} / \mathrm{L}^{3}\right)^{*} 100\right)$, where W is round or gutted weight $(\mathrm{kg})$ and L is length ( cm ). The relative size of the liver (liver index) was expressed the same way. Mean condition at age was calculated by weighting each individual fish condition by the ratio of the population number per 3 cm length class to the number of fish sampled in the same length class.

## Sentinel surveys in 1995

## Biological sampling

Sentinel surveys for cod were conducted by fishing enterprises operating from 15 communities in Subdivision 3Ps during the winter-summer (February-July) and autumn (September-December) of 1995 (Davis 1995). To obtain information on feeding and well-being, samples of cod were collected by 14 of these enterprises, frozen and transported to the Northwest Atlantic Fisheries Centre in St. John's. The objective during the winter-summer period was to obtain one sample of 2 fish per cm from each location every two weeks. The objective remained unchanged during the autumn, except that the sampling rate was reduced to 1 fish per cm .

The frozen fish were thawed in fresh water and weighed (to the nearest 10 g ) before being cut (round weight) and again after removal of the organs from the abdominal cavity (gutted weight). The liver and gonad were also weighed ( g ). The stomach contents were separated into species or higher taxa, and the specimens in each taxon were counted and weighed to the nearest 0.1 g .

Data analysis

The condition and liver index were calculated as described above.

The relative importance of specific prey taxa was expressed as percent occurrence (number of stomachs containing the prey as a percentage of the total number of stomachs, including empty stomachs), percent by weight (weight of specific prey in all stomachs as a percentage of the total weight of all prey in all stomachs) and as a partial fullness index (Fahrig et al. 1993):

$$
P F I_{i}=\frac{1}{n} \sum_{j=1}^{n} \frac{W_{i j}}{L_{j}^{3}} * 10^{4}
$$

where $W_{i j}$ is the weight ( $g$ ) of prey $i$ in fish $j, L_{j}$ is the length ( cm ) of fish $j$, and $n$ is the number of fish in the sample. This index is based on the assumption that stomach capacity is a power function of length, and is analogous to Fulton's condition factor. The total fullness index (TFI) is the sum of all partial fullness indices.

## Results and Discussion

## Research vessel surveys

Mean lengths at age
Mean lengths-at-age (Table 6; Fig. 1) varied over time. For the period 1972-1996, peak length-at-age occurred in the mid-1970s for young ages (3-4) and progressively later to $198 \overline{0}$ for older ages. During the past decade, length-at-age varied with no trend (younger ages) or declined (older ages). The changes in mean weights-at-age (Table 7; Fig. 2) appear very similar to those for mean lengths. Further examination of variability in growth will focus on lengths only, because there is evidence that the weight of the muscle mass and liver undergo changes during the winterspring period (see section on condition).

There are some unexpected year effects in the length-at-age data, as illustrated in a plot of the increase in length of individual cohorts (Fig. 3) and a plot of annual length increments for ages 2 to 8 (Fig. 4). There appears to be negative growth for at least 2 cohorts during each of the intervals 1977-1978, 1980-1981, 1989-1990 and 1993-1994. Apparent negative growth could result from decreased availability of the larger fish within each cohort. This could be caused by relatively high mortality of larger fish or differences in migration patterns of larger and smaller fish within each cohort. Apparent negative growth could also result if the survey area contained different "groups" of fish with different growth rates, and the proportion of each group in the sampling varied from year to year. There is good evidence that the $3 \mathrm{P}_{\mathrm{s}}$ stock consists of several stocks or substocks, but it has not yet been demonstrated that these smaller units experience different growth rates. There is also a possiblity that the degree of inclusion of adjacent stocks may vary from year to year. Pinhorn (1969) reported that cod from Burgeo Bank grow faster than those from 3Pn, and the degree to which 3Pn4RS cod occur within 3Ps probably varies among years (D'Amours et al. 1994). There may also be annual variability in the presence of 3NO cod, which grow relatively quickly (Fleming 1960).

Additional exploration of the annual variablity in length increments followed the approach of Shelton and Lilly (1995) and Shelton et al. (1996). A multiplicative model accounting for age effects was fitted to the logarithm of the annual increments,

$$
\operatorname{Ln}\left(\mathrm{X}_{\mathrm{ij}}\right)=\alpha_{\mathrm{i}}+\varepsilon
$$

where $X_{i j}$ is the mean length increment at age $i$ in year $j, \alpha_{i}$ is the age effect, and $\varepsilon$ is normally distributed error. Analysis was limited to ages 2 to 6 , because length at age 1 was usually based on a small sample size and was sometimes missing, and growth at ages greater than 6 was
sometimes negative. The model explained $26 \%$ of the variance in the logarithm of the annual length increments (Table 8). The mean annual residuals (Fig. 5) show some of the effects noted above. For example, the three strongest negative residuals (1977, 1989, and 1993) occurred during years when apparent negative growth was observed in older ages. The negative residual in 1995 may be related to the change in gear from the Engels high lift trawl to the Campelen trawl. The latter trawl is much more effective at catching small fish.

There are several factors which may have contributed to the observed differences in growth. (1) As noted above, it is possible that the sampling of different "groups" of fish varied among years. The distribution of sampling relative to the distribution of different "groups" of cod should be investigated. (2) The timing of the surveys differed among years, so the duration between samples varied considerably. However, this may not present a problem, because there are reasons to suspect that increase in length does not occur during the winter-spring period. Pinhorn (1966) reported that otolith growth of west Newfoundland cod, caught off southwestern Newfoundland, starts in July and continues until December. Condition (somatic condition and liver index) of cod taken in the 1995 sentinel survey decreased during the winter-spring (see below), and it is unlikely that linear growth would occur while condition was declining. Average spawning time for cod on St. Pierre Bank is mid-May (Hutchings and Myers 1994), and again it is unlikely that linear growth would occur in mature cod at a time when they put much of their energy into reproduction. In addition, cod sampled during several of the winter-spring bottomtrawl surveys had little food in their stomachs (unpubl. data). Despite these reasons for suspecting that linear growth does not occur during the period over which the surveys have varied, a check for the influence of differences in duration between successive surveys should be conducted. (3) A third factor which may have caused some of the annual variability in length-at-age is temperature, which is a strong determinate of growth in northern cod and other cod stocks (Shelton et al. 1996, and references therein). Time-series of temperature are provided by Hutchings and Myers (1994) and Colbourne (1996), but perhaps the influence of temperature on growth should not be investigated until there is resolution of the questions noted above regarding sampling of different "groups" of fish and the possible influence of differences in survey timing.

## Cod well-being

Gutted condition: Mean gutted condition at age (Table 9; Fig. 6) generally fluctuated without trend. Values tended to be high in some years, notably 1983, and low in other years, especially 1993 and 1994. Among-year comparisons are confounded by the considerable differences in timing of the surveys. As a preliminary examination of the influence of timing, the mean condition for each of three $9-\mathrm{cm}$ length-groups was plotted against the median date of the survey (Fig. 7). There appears to be a slight decline from the earliest median date (day 56 - February 25) to approximately day 105 (mid-April), after which there is an increase. Thus, the low values in recent years (1993-1996) may be due primarily to the timing of the surveys. This interpretation must be tested further, because condition levels tended to be relatively high in 1984, the only earlier year in which the survey was conducted at about the same time as the 1993-1995 surveys.

Liver index: Mean liver index at age (Table 10; Fig. 8) had a stronger year-to-year pattern than did gutted condition. The high values of 1983 are more pronounced and there is a strong peak in
the late 1980s and early 1990s. When mean liver index is plotted against median survey date (Fig. 9), there is a distinct decline to approximately day 105, followed by an increase. As with the gutted condition, the low values in recent years are seen to result from sampling at the nadir of the seasonal cycle.

## Sentinel surveys in 1995

## Cod well-being

Samples were collected by fishing enterprises operating from 14 communities (Table 11). Samples were obtained by each enterprise on 2-14 occasions, yielding a total of 126 collections and 2903 fish. Individual samples consisted of 1-58 fish (median =23).

Because Fulton's condition increases with cod length, it is necessary to employ a relatively narrow range of fish length when examining spatial and temporal variability in condition. The cod sampled during the surveys varied from 18 to 104 cm (Table 11). Cod from linetrawls had a broader size range than those from gillnets, but cod from the latter tended to be larger (Fig. 10). This is probably the result of differences in gear selectivity, but the possibility of spatial differences in availablility of fish by size cannot be ruled out, because at no time were the two gears fished side-by-side. For analysis of condition, a length range of $45-71 \mathrm{~cm}$ was arbitrarily chosen. (The boundaries may seem odd, but they are chosen to facilitate comparison with data collected during offshore surveys, where samples for condition were collected by $3-\mathrm{cm}$ length-groups prior to 1994 and samples for stomach content analysis were collected by $9-\mathrm{cm}$ length-groups.)

Both gutted condition and liver index underwent a seasonal cycle, with a low point in spring (probably in May) and a peak in summer (Fig. 11). The peak is very poorly defined because of the paucity of sampling. Cod caught west of the Burin Peninsula (dark symbols in Fig. 11) appear to have lower liver indices in the first half of the year than do cod caught in Placentia Bay. There is considerable variability in condition during the autumn. This was also the case with cod caught during the autumn 1995 sentinel survey in Division 2J3KL (Lilly 1996).

Stomach contents
Most of the sampled cod had very little food in their stomachs (Table 12). The average total fullness index for all 2545 stomachs combined was just 0.53 , which is very low considering that values as high as 20 have been found in individual cod and average values greater than 10 have been found in certain samples, particularly those taken from cod which had been feeding intensively on capelin in the inshore (Lilly and Osborne 1984). However, a low level of stomach fullness is not unusual for cod in the inshore at times other than when capelin are available (Lilly and Botta 1984).

The most frequently occurring prey were hyperiid amphipods. Prey which contributed most to the weight of the pooled stomach contents were capelin (Mallotus villosus), hyperiids,
ophiuroids (brittle stars), snow crabs (Chionoecetes opilio) and toad crabs (Hyas araneus and H . coarctatus). The major contributors to the fullness index were capelin and hyperiids. Commercial fish other than capelin included redfish (Sebastes sp.), herring (Clupea harengus) and cod. There were several species of shrimp, the most important of which was Lebbeus polaris. It must be emphasized that Table 12 is a summary of the stomach contents of those cod sampled during the sentinel surveys. Extrapolation to the prey composition of the population of cod in the inshore regions of Subdivision 3Ps will require several additional steps, including adjustments for the length-stratified sampling, some adjustment for the selection characteristics of the gears, and a weighting of each sample to account for temporal/spatial variability in fish density. The paucity of data from the summer period, when feeding may be most intense, precludes any attempt at calculating the prey composition of the cod population at this time.

The total fullness index and the partial fullness indices for eight categories of stomach contents (including bait) are provided for each sample in Table 13. The total fullness index was low in most samples. Two high values ( 6.8 at Monkstown on July 6 and 6.6 at St. Brides on July 19) are associated with intensive predation on capelin. The highest value for the liver index ( 0.069 ) also came from the St. Brides sample on July 19. A rapid increase in liver index occurs when cod feed intensively on capelin in inshore waters during the early summer (Lilly 1996; unpubl. data). Most of the moderately high TFI values (ie. those between 1.0 and 2.0) are associated with feeding on capelin or hyperiid amphipods.

It must be emphasized that the above descriptions of condition and feeding are only initial attempts at understanding these aspects of the cod's life in inshore waters. These data must be examined in relation to other observations on the actual fishing grounds (as opposed to simple reference to the community from which each fishing enterprise operated). Other observations of interest include C/E data, tag return data, cod length-at-age (and hence growth), stage of maturity and various quantitative and qualitative observations regarding the physical and biotic environment.

## Were any cod in critical condition?

Some of the gutted condition levels and liver indices found during the sampling in Subdivision 3Ps appear low compared with levels observed in offshore and inshore cod of Divisions 2J3KL (Taggart et al. 1994; Lilly 1996). Data must accrue for several years before the seasonal pattern of "normal" condition levels can be determined for both 3Ps cod and 2J3KL cod, and before it can be determined if there are regional differences in timing and amplitude of these cycles. Note that accurate determination of the cycles will require sampling at each site throughout the year, with sampling perhaps being most frequent during the times of spawning and intense feeding (spring and summer).

It is not yet known if any of the condition levels found during this study are indicative of fish in critical condition. Dutil et al. (1995) have provided metrics for what they consider to be fish in a jeopardized state, based on their laboratory studies of Gulf of St. Lawrence cod, but the condition formulations which they have used cannot be applied directly to the data available for
cod in Subdivision 3Ps. Following additional analyses, it should be possible to make certain simplifying assumptions and cast the data for 3Ps cod in a way which permits direct comparison with their values.

${ }^{a}$ This survey is not considered to be part of the time-series. The survey time was changed to April to reduce the chances of catching cod from the 3Pn4RS stock.

Table 2. Instructions for sampling cod during bottom-trawl surveys in Subdivision 3Ps in 1972-1996. The instructions were extracted from unpublished trip reports available in the library of the Northwest Atlantic Fisheries Centre, St. John's, NF. In each of the sample descriptions, the numbers in parentheses are stratum numbers.

| Year | Trip | Sampling the unfrozen fish | Sampling of frozen fish |
| :---: | :---: | :---: | :---: |
| 1972 | ATC 197 | For the Subdivision, collect otoliths from cod $<32 \mathrm{~cm}$; 5 per $3-\mathrm{cm}$ group $\operatorname{cod} \quad 33-62 \mathrm{~cm} ; 15$ per $3-\mathrm{cm}$ group cod $63-101 \mathrm{~cm} ; 30$ per $3-\mathrm{cm}$ group cod 102-116 cm; 15 per 3-cm group cod $>116 \mathrm{~cm} ; 5$ per 3-cm group |  |
| 1973 | ATC 207 | As in 1972 |  |
| 1974 | ATC 221 | As in 1972 |  |
| 1975 | ATC 234 | As in 1972, except for cod $33-62 \mathrm{~cm} ; 30$ per $3-\mathrm{cm}$ group |  |
| 1976 | ATC 247 | For the Subdivision, collect otoliths from 25 specimens per $3-\mathrm{cm}$ group |  |
| 1977 | ATC 261 | As in 1976 |  |
| 1978 | ATC 273 | As in 1976 | For the Subdivision, freeze 5 specimens per 3 -cm group |
| 1979 | ATC 287 | As in 1976 | As in 1978 |
| 1980 | ATC 302 | For the Subdivision, collect otoliths from 25-30 specimens per $3-\mathrm{cm}$ group | As in 1978 |
| 1981 | ATC 316 | As in 1976 | As in 1978 |
| 1982 | ATC 330 | As in 1976 | Instructions not recorded, but sample obtained |
| 1983 | AN 9 | As in 1976 | As in 1978 |
| 1984 | AN 26 | As in 1976 | As in 1978 |

Table 2 (cont'd)

| Year | Trip | Sampling the unfrozen fish | Sampling of frozen fish |
| :---: | :---: | :---: | :---: |
| 1985 | WT 26 | For each of two samples, collect otoliths from 25 specimens per $3-\mathrm{cm}$ group. <br> Samples are: <br> (1) Burgeo Bank (306-309) <br> (2) St. Pierre Bank (all other strata, but excluding 714-716) <br> For each sampled fish, also obtain: <br> volume of liver <br> volume of gonad | For each of two samples, freeze 5 specimens per $3-\mathrm{cm}$ group. Samples are: <br> (1) Northwest St. Pierre Bank (310-312) <br> (2) Halibut Channel $(315,318,319)$ |
| 1986 | WT 45 | As in 1985 | As in 1985 |
| 1987 | WT 55, 56 | As in 1985 | For each of two samples, freeze 5 specimens per 3-cm group. Samples are: <br> (1) Northwest St. Pierre Bank (310-314) <br> (2) Burgeo Bank (306-309) |
| 1988 | WT 68 | For the Subdivision, collect otoliths from 25 specimens per $3-\mathrm{cm}$ group <br> For each sampled fish, also obtain: volume of liver volume of gonad | As in 1987 |
| 1989 | WT 81 | As in 1988 | For each of three samples, freeze 5 specimens per 3-cm group. <br> Samples are: <br> (1) Northwest St. Pierre Bank (310-314) <br> (2) Burgeo Bank (306-309) <br> (3) Green Bank - Halibut Channel (east of 55010' W) |
| 1990 | WT 91 | For the Subdivision, collect otoliths from 25 specimens per $3-\mathrm{cm}$ group <br> For each sampled fish, also obtain: <br> round weight <br> gutted weight <br> weight of liver (volume if liver $<100 \mathrm{~g}$ ) <br> weight of gonad (volume if gonad $<100 \mathrm{~g}$ ) | As in 1989 |

(cont'd)

Table 2 (cont'd)

| Year | Trip | Sampling the unfrozen fish | Sampling of frozen fish |
| :---: | :---: | :---: | :---: |
| 1991 | WT 103 | For the Subdivision, collect otoliths from 25 specimens per $3-\mathrm{cm}$ group <br> For each sampled fish, also obtain: <br> round weight <br> gutted weight <br> weight of liver <br> weight of gonad | As in 1989, except that in addition determine round weight at sea |
| 1992 | WT 118 | As in 1991 | As in 1991 |
| 1993 | WT 133 <br> (February) | As in 1991 | As in 1991 |
|  | WT 135 <br> (April) | For the Subdivision, collect otoliths from 10 specimens per $3-\mathrm{cm}$ group <br> For each sampled fish, also obtain: <br> round weight <br> gutted weight <br> weight of liver <br> weight of gonad | For each of four samples, freeze 5 specimens per 3-cm group. <br> Samples are: <br> (1) Northwest St. Pierre Bank (310-314, 705, 713) <br> (2) Burgeo Bank (306-309, 714-716) <br> (3) Green Bank - Halibut Channel $(318,319,707-709)$ <br> (4) Remaining strata (315-317, 320-326, 706, 711, 712) <br> Determine round weights at sea |
| 1994 | WT 150, 151 | For the Subdivision, collect otoliths from 2 specimens per cm <br> For each sampled fish, also obtain: round weight gutted weight weight of liver weight of gonad | For each of five samples, freeze 2 specimens per cm Samples are: <br> (1) Northwest St. Pierre Bank (310-314, 705, 713) <br> (2) Burgeo Bank (306-309, 714-716) <br> (3) Green Bank - Halibut Channel (318, 319, 325, 326, 707-710) <br> (4) Placentia Bay (779-783) <br> (5) Remaining strata (315-317, 320-324, 706, 711, 712) |
| 1995 | WT 166, 167 | As in 1994 (However, instructions for WT. 166 specified 10 specimens per cm , whereas instructions for WT. 167specified 2 per cm ) | Determine round weights at sea <br> As in 1994 (Areas specified in instructions for WT. 167, but not for WT. 166) |
| 1996 | WT 186, 187 | As in 1994 | As in 1994 |

Table 3. Sampling of cod caught during bottom-trawl surveys in Subdivision 3Ps in 1972-1996. Number of aged fish for which there are also records of length, body weight and liver size (weight or volume).

| Year | Length | Body weight |  | Liver |  |  |

Table 8. Growth of cod in Subdivision 3Ps as determined from sampling conducted during winter-spring bottom-trawl surveys in 1978-1996. Results of the general linear model in which age effects were fitted to the log transformed annual mean length increment data for ages 2-6. (The length increment for age 2 is the increase in mean length from age 2 in year $t$ to age 3 in year $t+1$ ).

General Linear Models Procedure (SAS)

| Class Level Information |  |  |  |
| :---: | :---: | :---: | :---: |
| Class | Levels | Values |  |
| AGE | 5 | 23456 |  |

Number of observations in data set $=119$

| Source | DF | Type I SS | Mean Square | F Value | $\operatorname{Pr}>F$ |
| :--- | :---: | :---: | :---: | :---: | :---: |
| AGE | 4 | 8.1723991 | 2.0430998 | 10.24 | 0.0001 |
| Source | DF | Type III SS | Mean Square | F Value | $\operatorname{Pr}>F$ |
| AGE | 4 | 8.1723991 | 2.0430998 | 10.24 | 0.0001 |

| Parameter | Estimate | T for H0: <br> Parameter $=0$ | $\operatorname{Pr}>\|\mathrm{T}\|$ | Std Error of <br> Estimate |  |
| :--- | :---: | :---: | :---: | :---: | :---: |
|  |  |  |  |  |  |
| INTERCEPT | 1.667084586 B | 18.28 | 0.0001 | 0.09118555 |  |
| AGE | 0.638129486 B | 4.90 | 0.0001 | 0.13035001 |  |
|  | 3 | 0.659219686 B | 5.11 | 0.0001 | 0.12895585 |
| 4 | 0.410009655 B | 3.18 | 0.0019 | 0.12895585 |  |
|  | 5 | 0.147563839 B | 1.14 | 0.2549 | 0.12895585 |
| 6 | 0.000000000 B | . | . | . |  |

NOTE: The $X^{\prime} \mathrm{X}$ matrix has been found to be singular and a generalized inverse was used to solve the normal equations. Estimates followed by the letter ' B ' are biased, and are not unique estimators of the parameters.

Table 9. Mean gutted condition at age of cod caught during winter-spring bottom-trawl surveys in Subdivision 3Ps.

| Age | 1978 | 1979 | 1980 | 1981 | 1982 | 1983 | 1984 | 1985 | 1986 | 1987 | 1988 | 1989 | 1990 | 1991 | 1992 | 1993 | 1994 | 1995 | 1996 |

Fig. 1. Mean length at ages 1-10 of cod in Subdivision 3Ps in 1972-1996, as determined from sampling during bottom-trawl surveys in winter-spring.

Fig. 2. Mean weight at ages 2-7 of cod in Subdivision 3Ps in 1978-1996, as determined from sampling during bottom-trawl surveys in winter-spring.

Fig. 3. Length ( cm ) at ages 1-12 of the 1962-1995 cohorts of Subdivision 3Ps cod, as determined from sampling during winterspring bottom-trawl surveys.

Fig. 4. Length increments ( cm ) for 3 Ps cod of ages 2 to 8 , as determined from sampling during winter-spring bottom-trawl surveys. The increment from year $t$ to year $t+1$ is referenced to year $t$.

Fig. 5. Annual variability in the growth of cod in Subdivision 3Ps, as determined from sampling conducted during winterspring bottom-trawl surveys. The plot shows annual residuals, averaged over ages 2-6, from the general linear model in which age effects were fitted to the log transformed annual mean length increment data (see Table 8).

Fig. 6. Mean gutted condition of ages 4-7 cod in Subdivision 3Ps in 1978-1996, as determined from sampling during bottom-trawl surveys in winter-spring.

Fig. 7. Mean gutted condition of cod of three length-groups as determined from sampling during bottom-trawl surveys in 1978-1996. The condition values for each year are plotted against the median day of sampling. For years 1993-1996 the median days were 103, 106, 108 and 115, respectively. The only year when sampling occurred at about the same time was 1984 ( median day $=105$ ).

Fig. 8. Mean liver index of ages 4-7 cod in Subdivision 3Ps in 1978-1996, as determined from sampling during bottom-trawl surveys in winter-spring.

Fig. 9. Mean liver index of cod of three length groups as determined from sampling during bottom-trawl surveys in 1978-1996. The liver index values for each year are plotted against the median day of sampling. for years 1993-1996 the median days were 103, 106, 108 and 115, respectively. The only year when sampling occurred at about the same time was 1984 (median day $=105$ ).

Fig. 10. Lengths (cm) of cod sampled from gillnet (GN) and linetrawl (LT) catches during sentinel surveys in Subdivision 3Ps in 1995. Each box plot illustrates the median, quartiles, 10th and 90th percentiles, and all data beyond the 10th and 90th percentiles.

Fig. 11. Condition of cod sampled during the sentinel survey in Subdivision 3Ps in 1995. The data are aggregated by community and day of year. Only cod in the length range $45-71 \mathrm{~cm}$ are included. Only points represented by at least 5 fish are plotted. In the legend, communities are ordered from west (top) to east. The black symbols indicate communities to the west of the Burin Peninsula.

[^0]:    ${ }^{\text {a }}$ Instances where liver volume was measured but not liver weight.

[^1]:    ${ }^{\text {a }}$ Percentage occurrence is provided only for taxa not initially identified at a lower level.
    ${ }^{\mathrm{b}}+$ indicates PFI < 0.0005
