# THE STATUS OF THE ATLANTIC SALMON STOCK OF THE HUMBER RIVER, NEWFOUNDLAND, 1995 

C.C. Mullins and D.G. Reddin<br>Department of Fisheries and Oceans<br>Science Branch<br>1 Regent Square<br>Corner Brook, Newfoundland<br>A2H 7K6

${ }^{1}$ This series documents the scientific basis for the evaluation of fisheries resources in Atlantic Canada. As such, it addresses the issues of the day in the time frames required and the documents it contains are not intended as definitive statements on the subjects addressed but rather as progress reports on ongoing investigations.

Research documents are produced in the official language in which they are provided to the secretariat.
${ }^{1}$ La présente série documente les bases scientifiques des évaluations des ressources halieutiques sur la côte atlantique du Canada. Elle traite des problèmes courants selon les échéanciers dictés. Les documents qu'elle contient ne doivent pas être considérés comme des énoncés définitifs sur les sujets traités, mais plutôt comme des rapports d'étape sur les études en cours.

Les Documents de recherche sont publiés dans la langue officielle utilisé dans le manuscrit envoyé au secrétariat.

#### Abstract

This is the sixth assessment of the Atlantic salmon stock of the Humber River. Indices of abundance are mark and recapture estimates of run size, angling catch and effort data and public consultations. Returns of small salmon in 1995 were the highest and large salmon were the second highest in six years of assessment which includesd two premoratoium years (1990 and 1991). Spawning escapements were above the conservation target in 1995 and in three out of four post-moratorium years compared to zero out of 12 pre-moratorium years since 1980 . Spawners replaced themselves in three out of four post-moratorium years compared to only four out of 12 pre-moratorium years since 1980 . Estimates of the total population size of salmon in pre-moratorium years, based on an assumed exploitation rate in the commercial fishery, indicate a significant decline since 1974. With the exception of 1995, the total population size of salmon on the Humber River during post-moratorium years has been among the lowest recorded.

The experience of anglers at public consultations in 1995 was that salmon were abundant on the river in the past season. Recreational catches of small salmon compiled by DFO in 1995 were above those in 1994 but below the 1992-1994 mean and below catches in pre-moratorium years. The interpretation of stock status based trends in recreational catch and effort data is confounded by the unknown effects of various catch and effort controls implemented in the fishery in recent years. In addition, as a result of less emphasis being placed on the collection of recreational catch data, the actual observed, as opposed to estimated, catches and effort reported in 1995 were only $35 \%$ of the total (observed + estimated) catch and effort compared to $80 \%$ in years prior to 1990 . The results of creel surveys at Big Falls suggest that angling catches on the Humber River are being underestimated by as much as $50 \%$.

The smolt age distribution of adult salmon on the river in 1994 and 1995 was approximately $50 \%$ age- 3 and $50 \%$ age-4. Assuming that this distribution remains unchanged, it will not be until 1997 and 1998 for small salmon and 1998 and 1999 for large salmon that the potential will exist for increased recruitment back to the river as a result of the moratorium. The recruitment back to the Humber River in 1996, based on the mean recruit/spawner ratio in 1992 1995, is anticipated to be less than in 1995.

RÉSUMÉ
Nous présentons la sixième évaluation du stock de saumon atlantique de la rivière Humber. Les indices de l'abondance sont fournis par les estimations de l'effectif de la remonte par marquage-recapture, les données sur les prises et l'effort de la pêche à la ligne, et la consultation publique. Les retours de petits saumons de 1995 étaient les plus élevés, et ceux de grands saumons étaient les deuxièmes en importance de la période d'évaluation de six ans, qui couvrait deux années pré-moratoire (1990 et 1991).Les échappées de géniteurs étaient au-dessus de la cible de conservation en 1995 et pendant trois des quatre années après moratoire, contre zéro des douze années pré-moratoire, depuis 1980. On note un renouvellement des géniteurs pendant trois des quatre années post-moratoire, alors qu'il n'avait eu lieu que pendant quatre des douze années prémoratoire depuis 1980. Les estimations de l'effectif total de la population avant le moratoire, d'après un taux d'exploitation supposé dans la pêche commerciale, indiquent une baisse nette depuis 1974. À l'exception de 1995, l'effectif total de la population de saumon de la Humber dans les années post-moratoire est le plus bas jamais enregistré.

Les pêcheurs sportifs consultés en 1995 ont signalé que les saumons étaient abondants dans la rivière au cours de la dernière saison. Les prises sportives de petits saumons, d'après les calculs effectués par le MPO en 1995, étaient supérieures à celles de 1994, mais inférieures à la moyenne de 1992-1994 et aux prises des années pré-moratoire. L'interprétation des tendances des prises et de l'effort de la pêche sportive par rapport à l'état du stock est compliquée par les effets inconnus de divers contrôles des prises et de l'effort mis en oeuvre dans la pêche ces dernières années. De plus, comme on accorde moins d'importance à la collecte de données sur la pêche sportive, les prises et l'effort réellement observés, au lieu d'être estimés, rapportés en 1995 correspondaient à seulement $35 \%$ du total des prises et de l'effort (observations + estimations) contre $80 \%$ dans les années antérieures à 1990 . Les résultats de l'enquête sur la pêche sportive menée à Big Falls permettent de penser que les prises sportives sur la rivière Humber peuvent être sous-estimées de $50 \%$.

La distribution des âges de smoltification des saumons adultes de la rivière en 1994 et 1995 était d'environ $50 \%$ d'âge - 3 et $50 \%$ d'âge - 4 . Si l'on pose que la distribution va rester identique, ce n'est pas avant 1997 et 1998 pour les petits saumons, et 1998 et 1999 pour les grands saumons, qu'on peut miser sur un accroissement du retour à la rivière par suite du moratoire. Le recrutement des saumons revenant à la rivière en 1996, d'après le rapport moyen recrue/géniteur de 1992-1995, semble devoir être inférieur à celui de 1995.

## INTRODUCTION

The Humber River is the largest river flowing into the Bay of Islands, situated in western Newfoundland at the northern limit of Salmon Fishing Area (SFA) 13 (Fig. 1). The Humber River comprises $95 \%$ of the drainage area of the Bay of Islands ( $8124 \mathrm{~km}^{2}$ ) which is $57 \%$ of the total drainage area of SFA 13 and flows into Humber Arm (Fig. 1) at latitude $48^{\circ} 57^{\prime} \mathrm{N}$ and longitude $57^{\circ} 53^{\prime} \mathrm{W}$. The total length of all tributaries in the Humber River is 2450.5 km . Complete obstructions to migrations of anadromous Atlantic salmon within the river system occur at Main Falls (Fig. 2) which is 112.6 kilometres from the river mouth and at Junction Brook which was diverted for hydroelectric development in 1925. The diversion of Junction Brook which flowed into the Humber River at Deer Lake resulted in the loss to the Humber River system of the anadromous salmon production potential of the Grand Lake system (Porter et al., MS 1974) (see Fig. 2). No fish passage facility was provided during the diversion to maintain upstream migration of fish stocks.

The Humber River, on average, is the largest producer of Atlantic salmon recreational harvests in Newfoundland and Labrador. Commercial and recreational salmon fisheries management measures implemented in Newfoundland and Labrador since 1978 that would have helped to conserve this stock include:

1. 1978 - commercial season shortened to June 1-July 10 from May 15-December 31.
2. 1984 - mandatory release of large salmon ( $\geq 63 \mathrm{~cm}$ fork length) in recreational fishery.
3. 1987 - recreational season bag limit of 15 small salmon ( $<63 \mathrm{~cm}$ fork length).
4. 1990-35 t commercial quota in SFA 13 commercial fishery.
5. 1991-25 t commercial quota in SFA 13; recreational season bag limit of 10 small salmon.
6. 1992 - five year commercial moratorium; recreational quota of 5,000 small salmon in SFA 13 reached on 1 August; Adies Lake (Fig. 2) quota of 100 small salmon not reached; a catch and released fishery was permitted from 2 August to 7 September after the quota was reached; recreational season bag limit of eight small salmon.
7. 1993 - recreational quota of 5,200 small salmon in SFA 13 (4,160 for June 5-July 31 and 1,040 for Aug. 1Sept.6) not reached; Adies Lake closed 31 July - quota of 100 small salmon not reached; daily bag limit of one fish; Cook's Brook was closed for the season.
8. 1994 - recreational season bag limit of three small salmon before 31 July and three after 31 July; Adies Lake closed 31 July - quota of 100 small salmon not reached; daily bag limit of two fish; daily catch and release limit of four fish.
9. 1995 - recreational season bag limit of three small salmon before July 31 and 3 after July 31; Adies Lake closed 30 July - quota of 100 small salmon not reached; daily bag limit of two fish; daily catch and release limit of four fish.

This is the sixth assessment of the status of the Humber River salmon stock since 1990. In 1990 and 1991, the stock achieved $60 \%$ and $27 \%$, respectively, of the target spawning requirement for the river (Chaput and Mullins MS 1991, 1992). In 1992, with the closure of the commercial salmon fishery and the implementation of effort controls in the recreational fishery, the spawning target was exceeded (117\%). In 1993, the stock continued to show signs of improvement, achieving $96 \%$ of the target. However, returns of adult salmon to the river in 1994, achieved only $40 \%$ of the spawning target. The low spawning escapement in 1994, compared to 1992 and 1993, is attributed to extremely low spawning success in 1989. The progeny of spawners in 1989 would have produced most of the recruitment in 1994.

The present assessment of the Humber River salmon stock provides updated recreational catches and effort information for 1995 and estimated spawning escapements following the methodology presented for 1990-1994 (Chaput and Mullins, MS 1991; Chaput and Mullins, MS 1992; Mullins and Chaput, MS 1993; Mullins and Chaput, MS 1995; Mullins and Reddin, MS 1995). The following topics are addressed:

1) analysis of annual trends in recreational catches and effort
2) verification by independent creel method, of the recreational catch statistics collected by the Department of

Fisheries and Oceans (DFO) for the Big Falls segment of the Humber River,
3) estimation of total returns and spawning escapements in 1995 based on the angling exploitation
rate on small salmon derived using mark-recapture methods and applied to the total recreational catch 4) updating of the biological characteristics of the Humber River Atlantic salmon stock for 1995, 5) examination of the effect of the 1995 management regulations on the spawning escapement to the Humber River,

## MATERIALS AND METHODS

## Recreational Fishery Statistics

The DFO catch statistics for the recreational fishery were compiled from river guardian and fisheries officer reports. The traditional methods used for summarizing these data are described in Mullins and Claytor (MS 1989) and Mullins et al. (MS 1989). Catch and effort for the Humber River are described by river segment (Fig. 1-2) and the standardized weeks used are described in Table 2. Weekly salmon angling reports have also been completed for the catch and release fishery since 1992. Salmon catches in the recreational fishery are categorized into small ( $<63 \mathrm{~cm}$ ) and large ( $\geq 63 \mathrm{~cm}$ ) size groups.

## Creel Survey at Big Falls

A creel survey to determine the angling catch at Big Falls was conducted between 17 June and 5 September 1995. The Big Falls segment of the Humber River (Fig. 2) was again selected for the survey because it is accessed by anglers from only two points and the average catch from this segment, based on DFO statistcs, has been $38 \%$ of the total Humber River catch since 1986.

A "bus route" design (Robson and Jones 1989; Chaput et al. MS 1992; Mullins and Chaput, 1993; Mullins and Chaput, MS 1995), in combination with lattice sampling (Robson, 1990), was used to obtain catch and effort data of anglers at the two access points (Appendix 1).

The sampling day was divided into four time periods: 0600-1000, 1000-1400, 1400-1800, and 1800-2200. Two time periods were sampled every census day. During each four-hour period sampled, the creel survey clerks interviewed anglers as they departed the fishing locations. The clerks recorded the number of hours fished by each angler, the number of salmon retained and released, and the number of carlin tagged salmon recaptured. Clerks were instructed to maintain records independent of those kept by DFO Guardians.

A stratum is a block of days treated as a unit. Weekly strata (seven days) were used at Big Falls in 1995. The number of time periods sampled within a stratum was dictated by the available resources. Sampling effort within strata consisted of five days per strata for the entire season. The days and the time periods within the day to be sampled were randomly selected within each stratum.

The total catch for each stratum (week) was obtained by weighting the observed sampling period matrix with the Horvitz-Thompson matrix which gives equal weight to the individual sampling periods within a stratum (Robson, 1990). The variance of the catch estimate was calculated for each stratum using the Yates-Grundy variance formulation (Robson, 1990). Totals and variance estimates of totals for combined strata were obtained by summation. The confidence intervals of the estimate were calculated using $\pm 2$ standard deviations.

## Estimation of Angling Exploitation Rate

Two tagging traps were operated in the estuary of the Humber River in 1995 (Fig. 1). Small and large salmon were marked with Carlin tags and released. Tags were applied using a double stainless steel wire attachment directly under the anterior end of the dorsal fin. All salmon captured in the two traps were measured (fork length 0.1 cm ), and scale sampled.

Lower Trap - This trap has been fished in the same location at Wild Cove, Humber Arm (Fig. 1), since 1990. The trap design and installation in 1995 were identical to the 1990-1994 tagging program.

Upper Trap - This trap was fished about 1.5 km upstream from the Lower trap (the same location as in 1993). This trap had been fished approximately 10 km further upstream in 1994.

Injured fish were not tagged and no tagging was conducted at water temperatures above 20 C . Therefore, tagging mortality is believed to be negligible.

All salmon tagged in 1995 were assumed to be destined for the Humber River. However, tagged salmon havebeen recaptured in the past (2-12 in 1990-1993) from Hughes Brook which flows into the Humber Arm about 3.0 km north of the Humber River estuary. An adjustment for tags destined for Hughes Brook in 1995 would have increased the angling exploitation rate estimate by a maximum of $0.4 \%$.

The angling exploitation rate (ER) on small salmon (retained) on Humber River in 1995 was based on the number of tags returned from retained small salmon, divided by the number of small salmon tagged at both tagging traps according to the formula:
$E R=$ Tags Recaptured (TR)/Tags Available (TA)
where:
$T R=$ Total Tags Returned $/$ Reporting Rate (RR)
TA $=$ Tags Applied $\times$ ( 1 - Tag-Loss Rate(0.009 x Median Days to Recapture))
and:

## $R R=$ Observed Tags Returned from Big Falls / Observed Tags Recaptured at Big Falls

The reporting rate (RR) or proportion of recaptured tags that were returned voluntarily by anglers in 1995 were estimated on the basis of recaptures observed by the creel survey clerks at Big Falls. Clerks were instructed to observe only and not to prompt anglers to return tags. Note: The ratio (tags/catch at Big Falls):(tags/catch for the rest of the river) does not give a valid estimate of the reporting rate because creel clerks did not observe $100 \%$ of the tags recaptured at Big Falls. Tags returned from small salmon that were unknown to be retained or released were apportioned into retained or released recaptures based on the relative proportions of known retained and released recaptures.

Tags available (TA) to anglers in 1995 were estimated from the number of tags applied to small salmon multiplied by the proportion of tags retained (1-Tag-Loss Rate) as in previous years. The tag-loss rate was estimated based on the proportion of 0.009 tags shed per day to recapture derived for Margaree River in 1992 (Chaput et al., MS 1993). The method of tag application to salmon in the Margaree River tagging program is the same as for the Humber River. Median days to recapture were determined according to (Sokal and Rohlf, 1969). However, it is noted that five Humber River small salmon tagged on 27-28 July 1995 and held in captivity until 23 November, had $0.0 \%$ tag-loss at the time of release, 119 days after being tagged.

Tags available to the retention fishery were not adjusted for tags returned from released small salmon as these fish would also have been available to retention angling for a period of time before recapture. If the number of tags returned from released fish had been adjusted for the period of time they were available to the retention fishery and excluded from the total number of tags available, the exploitation rate calculation would have increased by less than $1.5 \%$.

## Estimation of Returns to the Humber River

The total recreational catch of small salmon retained on the Humber River was estimated based on the catch of small salmon recorded by the creel survey clerks at Big Falls and the proportion of tag returns recaptured by angling at Big Falls.

## Adjusted Catch (AC) $=$ Catch at Big Falls (Creel) $/$ Proportion Tags at Big Falls

In previous assessments the proportion of the total river harvest angled at Big Falls was estimated by two methods: 1. the proportion of catch reported from Big Falls in the DFO catch statistics and 2. the proportion of tags returned from Big Falls. In 1995, only the tags method was used.

Catches of small salmon recorded by the creel survey clerks at Big Falls were from immediately below (1-2 km ) the falls area and did not include the pools further downstream (Mistaken Point area) which were accessed via another route, but which would have been included in the DFO catch statistics for the Big Falls segment (Fig. 3). As a result the catch recorded by the creel survey clerks at the falls was adjusted to give a catch for the entire Big Falls segment. This was done based on the proportion of Big Falls tags recaptured at the falls area.

The number of small salmon that returned to the Humber River in 1995 was estimated by two methods based on total adjusted catch of small salmon retained, adjusted tags available to angling, and adjusted recaptures:

1. Petersen (Single Census) method (Ricker, 1975) according to the formula:

Returns of Small $(R S)=A C / E R$
2. maximum-likelihood stratified design following the method of Dempson and Stansbury (1991) and Darroch (1961).

For the maximum-likelihood estimate, the number of tags released and tags recaptured were initially stratified into six release and seven recapture intervals of two weeks each. The original matrix was collapsed to reduce the number of intervals with zero releases or recaptures.

The number of large salmon on the Humber River in 1995 was estimated by applying the ratio of large to small salmon captured in the two tagging traps to the estimate of small salmon returns where:

## Returns of Large (RL) $=$ RS $x$ (Ratio of Large:Small at Tagging Traps)

In the 1990 and 1991 assessments, the appropriate ratio of large to small salmon returns to the river was considered to be equivalent to the ratio of large to small salmon in the recreational fishery prior to $1984(7 \%)$ when large salmon could be retained (Chaput and Mullins, MS 1991, 1992). However, a commercial fishery was also permitted in these years. Because of the closure of the commercial fishery in 1992 and the potential for an increase in the river escapement of large salmon, the ratio of large to small salmon captured at the tagging traps is considered to be more representative of returns to the river in 1995 .

## Biological Characteristics

Biological characteristics of Humber River salmon in 1995 were obtained from bright salmon at the tagging traps and from angling catches at the Big Falls segment of the Humber River. The fish were sampled for fork length ( 0.1 cm ) and whole weight ( 0.1 kg ) and sex determination which was by internal examination except on live fish. Scale samples were obtained for determining the river-age and sea-age. These methods were identical to those used in 19901994.

## Estimation of Potential Egg Depositions

The potential egg depositions were calculated using the estimated spawning escapement and observed biological characteristics (mean weight of females, percent female, fecundity) of small and large salmon in 1995. The spawning escapement was obtained by subtracting the adjusted total recreational catch of small salmon retained from the estimated returns to the river.

The target egg deposition requirement for the Humber River was calculated using an optimal egg deposition for fluvial and lacustrine parr rearing area (Mullins and Chaput, MS 1995). The egg deposition rate used for fluvial area was $2.4 \mathrm{eggs} / \mathrm{m}^{2}$ as described by Porter and Chadwick (MS 1983) and the egg deposition rate used for lacustrine area was 368 eggs/ha as described by O'Connell et al. (MS 1991).

## Number of Recruits and Spawners, 1974-95, and Anticipated Returns in 1996

O'Connell, et al. (1995) described a technique whereby it was possible to retrospectively construct total population size of small salmon (or total number of small salmon recruits) prior to any exploitation in selected rivers with counting facilities and to use the number of salmon recruits per spawner to estimate anticipated returns one year in advance. The technique is fully described in O'Connell, et al. (1995) and equations used to derive recruits and spawners for the Humber River salmon stock are the same with the exception that large salmon are included (exploitation rate in commercial fishery $=0.80$ ) and that estimated small and large recruits have been weighted by the mean proportion of virgin 1SW and 2SW salmon in 1989-1995. However, spawning escapements are based on both virgin and repeat spawners.

## Analysis to Detect Recruitment Overfishing

Details on analysis to detect recruitment overfishing are provided by O'Connell, et al. (1995). Spawning escapements which produced total small and large salmon spawners on the Humber River in 1980-1995 were constructed by weighting previous spawning escapements by the smolt age distribution of 1 SW salmon on the Humber River in 1993.

## RESULTS

## Recreational Effort and Catches

The recreational angling season on the Humber River opened on 3 June and closed on 4 September 1995. The Adies Lake quota of 100 small salmon was not reached but this segment closed to fishing on 30 July. The opening and closing dates and bag limits were essentially the same as in 1994.

The catch of small salmon retained on the Humber River in 1995, according to DFO catch statistics, was 1,825 fish, which was approximately $18 \%$ above the catch reported in 1994, but it was $9 \%$ below the 1992-1994 mean (Fig. 4) and $29 \%$ below the 1987-1991 mean (Table 4). Retained and released catches in 1995, similar to retained catches, were above those in 1994, but unlike retained catches, were $5 \%$ above the 1992-1994 mean (Table 4). This may be due to an increase in the proportion of small salmon hooked and released in 1995 compared to previous years.

Released catches of small salmon in 1995, were $52 \%$ above those in 1994 and $28 \%$ of the total retained and released catches in 1995 up from $23 \%$ in 1994 (Table 4). Released catches were reported to be $21 \%$ of the total in 1993 and only $8 \%$ of the total in 1992. Released catches of large salmon in 1995 were $40 \%$ above those in 1994 and $49 \%$ above the 1992-1994 mean (Table 4).

Angling effort in 1995, similar to catches, was $21 \%$ above the effort in 1994, 10\% above the 1992-1994 mean
and similar to the 1987-1991 mean and 12\% below the effort in 1977-1986 (Table 4).
The highest angling effort reported in 1995 was at Big Falls followed by Harrimans Steady and the Lower Humber River. However, the effort on the Lower Humber peaked in week 32 compared to weeks 26-27 at Harrimans Steady and Big Falls. Effort in the Lower Humber was directly primarily at large salmon and produced the highest catches of large salmon on the river (93) in 1995.

The highest catches of small salmon retained were at Big Falls (549) and Harrimans Steady (514). The catch of small salmon retained at Big Falls was 30\% of the Humber River catch in 1995 compared to $42 \%$ in 1994, 40\% in 1993, $63 \%$ in 1992, and an average of $40 \%$ in 1984-1992.

The catch-per-unit-effort (CPUE) of small and large salmon retained and released on the river in 1995 was no higher (within 10\%) than in 1994 or the mean since 1977 (Table 4).

The actual observed effort and catch recorded in the DFO catch statistics in 1995 accounted for only $35 \%$ of the total observed and estimated effort and catch (Table 5). This compares with 30\% in 1994 (Mullins and Reddin, 1995) but is much lower than the $80 \%$ observed reported in years prior to 1990 (Mullins and Claytor 1989).

## Creel Survey Catches at Big Falls

A total of 1,244 anglers were interviewed or observed by the creel survey clerk located at Big Falls in 1995 (Table 6). Anglers fished for an average of 3.80 hours which was similar to the effort expended in 1994 and 1993, but $14 \%$ below effort in 1992. The total catch observed was 375 small salmon retained and 137 released, and 17 large salmon released. The catch of small salmon retained per unit of effort (CPUE) for interviewed anglers was the highest in the last three years that the survey was conducted.

The creel survey estimate of small salmon retained at Big Falls in 1995 was $1,853(\mathrm{CI}=1,639-2,068)$ which was more than three times the DFO estimate of 549 (Table 7a). The distribution of retained catches estimated by the creel survey and the DFO methods were quite similar, with the exception of week 3 (July 1-7), which was the week of peak catches for both methods (Fig. 5). The creel survey estimate of small salmon released at Big Falls was 678 (CI=512-844) which was more than five times the DFO estimate of 127 (Table 7b) but the weekly distribution of released catches was similar for both methods (Fig. 6). The creel survey estimate of large salmon released was 104 ( $\mathrm{CI}=36-172$ ) compared to the DFO estimate of 47 (Table 7c). The distribution of large salmon released was similar for both methods and the week of peak catches occurred one week earlier than catchesof small salmon retained or released (Fig. 7). The amount of angling effort could not be directly compared between the two methods because the angling effort recorded by DFO was in rod days and the creel effort was in hours fished. However, as for catches, the distribution of weekly angling effort was similar for the two methods but with less difference between the two during the peak week (Table 7d; Fig. 8).

## Estimation of Angling Exploitation Rate

The Lower estuarial tagging trap was operated from 7 June to 18 September and the Upper Trap was operated from 2 June to 31 August 1995. A total of 145 large and 1960 small bright salmon were captured in both traps (Table 8). The ratio of large:small salmon captured in 1995 was $0.0740: 1$ which was $42 \%$ below the ratio of large:small salmon in 1994 and $110 \%$ above 1993.

The distribution of catches was earlier for the tagging trap located further downstream. Peak catches of small salmon occurred in late June in both traps (Fig. 8a-b). However, the majority of catches in the Lower trap occurred in early June while those in the Upper trap occurred in early July. The peak catches of large salmon in the Lower trap occurred in early June but later in June and in July in the Upper trap.

In general, tag releases from the Lower trap peaked two weeks earlier than in the Upper trap (Table 9; Fig. 9). A total of 1,912 ( 821 Lower and 1,091 Upper) small bright salmon and 136 (99 Lower and 37 Upper) large salmon were tagged and released from the two traps (Tables 9, 10). Tagging was not carried out at surface water temperatures above 20 C and the number of tags returned did not appear to be related to the water temperature at the time of tagging (Table 11).

Recaptures from angling of salmon tagged in the Lower trap were about one week earlier than salmon tagged in the Upper trap (Fig 10). However, the distribution of recaptures from the two traps combined, was similar to the distribution of angling catches for small salmon (Fig. 11) indicating that tagged fish from both traps were evenly dispersed in the population and available to the fishery at the same time as untagged fish.

Tagged small salmon were recaptured on all major segments of the Humber River (Table 12). The largest number were recaptured at Big Falls (104) and Harrimans Steady (55). A total of 236 recaptured tags was returned from retained and released small salmon and six from released large salmon (Table 13).

The median number of days at large before recapture of tagged small salmon was 13.4 days (Table 14). This was similar to the mean number of days at large for tagged salmon in 1993 and 1994. The minimum was zero days and the maximum was 71 days. The estimated overall proportion of tags retained in this period were 0.880 (1-( $0.009 \times 18$ days)).

Out of a total of 23 Carlin tags which were removed from angled (retained and released) small salmon and observed by four creel survey clerks located on different sections of the Humber River in 1995 (Table 6), 60.87\% were (14) subsequently returned voluntarily by the anglers. This is similar to the repoting rate of 0.64 estimated in 1994 (Mullins and Reddin, MS 1995) and the rate of 0.75 which was assumed for the Humber River assessment in 1993.

After adjustment for tag loss and reporting rate, the angling exploitation rate for 1995 was 0.1846 (Table 14). This was the lowest rate in six years of assessment ( 0.25 in 1990-1991; 0.22 in 1992; 0.2213 in 1993; and 0.2865 in 1994). Angling exploitation was highest on salmon tagged and released early in the run (week 24-25) and ranged from $0.16-0.25$ throughout (Table 14). The range of exploitation rates indicates that, to some extent, the fishery harvested certain portions of the salmon run more than others. However, in general, the difference in exploitation rates between the various two week periods of tagging was relatively low. Therefore, it is expected that a stratified estimate of the population by two week intervals would not yield a significantly different estimate than an overall estimate based on the average exploitation rate for the season.

## Biological Characteristics

Small salmon captured in the tagging traps and in angling on the Humber River in 1995 were primarily ( $99 \%$ ) virgin one-sea-winter (ISW), whereas, large salmon were primarily ( $55 \%$ ) repeat spawning grilse which was comparable to previous years (Table 15a-b). The average sea age composition of Humber River salmon in 1989-1995 is $96.9 \%$ ISW for small and $42.4 \%$ 2SW for large.

The mean weight of small female salmon sampled in the recreational fishery in 1995 was $1.60 \mathrm{~kg}(\mathrm{~N}=18)$ and the sex composition was $51.4 \%$ female ( $\mathrm{N}=72$ ) (Table $16 \mathrm{a}-\mathrm{b}$ ). For the second consecutive year the smolt-age distribution of angled and tagged virgin 1 SW salmon was divided almost equally between age- 3 and age- 4 smolts (Table 19). In $1995,47 \%$ were smolt-age- 3 , and $52 \%$ were age- 4 (Table $17 \mathrm{a}-\mathrm{b}$ ). Prior to 1994 the predominant smolt age-class was three years. This was similar to the smolt-age of virgin 2 SW salmon in 1995 but in 1994 smolt-age- 3 was the predominant age-class of 2SWs (Table 17).

## Returns and Escapements to the Humber River.

The adjusted catch of small salmon retained at Big Falls was 2,534 (95\% CI=2,386-2,669) and the adjusted catch of small salmon retained on the whole river was $5,150(95 \% \mathrm{CI}=4,799-5,557)$ (Table 18). On the basis of the adjusted number of tagged small salmon available to angling and the adjusted number of tags returned by anglers, the Petersen (single census) method estimated that $27,898(95 \% \mathrm{CI}=25,001-31,232)$ small salmon returned to the river in 1995 (Table 19). Based on the ratio of large:small salmon caught in the tagging traps, 2,064 ( $95 \% \mathrm{CI}=1,757-2,360$ ) large salmon also entered the river in 1995 (Table 19).

The Darroch maximum-likelihood stratified estimate of small salmon abundance in 1995 was 27,254 (95\% $\mathrm{CI}=24,428-30,080$ ) which was less than $5 \%$ below the Petersen estimate (Table 19).

The potential spawning escapement on the Humber River in 1995 was 22,748 small and 2,064 large salmon. Both of these stock components were above their respective target spawner requirements (Fig. 12).

These spawning escapements of small and large salmon in 1995 would have resulted in an egg deposition which was $129 \%$ of the target egg deposition requirement (Table 20). This was the largest spawning escapement of small salmon and the second largest escapement of large salmon spawners achieved since the closure of the commercial salmon fishery in 1992 (Table 21).

## Number of Recruits and Spawners, 1974-95, and Anticipated Returns in 1996

The outcome of calculations of total numbers of salmon recruits, numbers of spawners, and numbers of recruits per spawner are shown in Figs 12-13. There was a lot of variability in recruitment from a given spawning escapement (Fig. 13a). Since 1974, there was a significant decline ( $\mathrm{r}^{2}=0.40 ; \mathrm{df}=19 ; \mathrm{P}<0.01$ ) in the total number of small and large salmon recruits for Humber River (Fig. 13d). Except for 1990, the lowest recruitment for the entire time series was experienced during the period 1989-1994. In fact, 1994 was the lowest. This trend appears to have been broken with the higher recruitment in 1995.

There was no identifiable trend in the total number of small and large spawners (Fig. 12c). Expressing target spawning requirements in terms of salmon adults (horizontal line in Fig. 12c), it is evident that target spawners were achieved in 1975-1976 and 1992-1993. Numbers of spawners in 1992-94 although declining over that period compare well with higher values in the past, particularly the late 1970 s and early 1980 s, and represent a substantial improvement over the lows observed for 1989 and 1991. Spawners in 1995 were the highest recorded.

The total number of salmon recruits produced per spawner showed no trend for small salmon ( $\mathrm{r}^{2}=0.13 ; \mathrm{df}=14$; $\mathrm{P}>0.05$ ) (Fig. 13b) but declined significantly for large salmon ( $\mathrm{r}^{2}=0.60 ; \mathrm{df}=13 ; \mathrm{P}<0.01$ ) (Fig. 13c). The number of small and large salmon recruits anticipated for 1996, based on the average number of small and large recruits produced per spawner for each river age grouping in 1993-1995, is approximately 15,710 small and large salmon.

Given a similar smolt-age distribution of 1SW salmon in 1996 to those in 1995, returns of 1SW salmon in 1996 will be influenced by the relatively high spawning escapement in 1990 and the relatively low escapement in 1991. The returns of 2 SW salmon in 1996, assuming a similar smolt-age distribution to those in 1995, will be influenced by the spawning escapements in 1989 and 1990 that produced the relatively high returns of 1SWs in 1995 (Fig. 14).

## Analysis to Detect Recruitment Overfishing

Since the closure of the commercial salmon fishery (1992-1995), the number of spawners on Humber River has been above estimates of their cohorts derived by weighting previous spawners by the smolt-age distribution of their progeny (Fig. 14). Spawners in 1992-1995 have been above the replacement (diagonal) line (Fig. 15). In two of the three years immediately preceding the moratorium, 1989 and 1991, numbers of spawners were well below the replacement line. Of the total number of 16 data points, eight were below.

## DISCUSSION

Recreational catches of small salmon compiled by DFO on the Humber River in 1995 increased in comparison to 1994 but not to the 1992-1994 mean or to pre-moratorium years.

The interpretation of annual trends in recreational catch and effort data is confounded by the unknown effect of the various catch and effort controls which have been implemented in the recreational fishery in recent years and have succeeded in keeping catches at a low level compared to historical levels. In addition, discrepancies exist between catch data reported by DFO at Big Falls on the Humber River and those based on creel survey results which suggest that total catches may be underestimated in the DFO catch statistics by as much as $50 \%$. This is not surprising given that the proportion of catches and effort actually observed, as opposed to estimated, by the DFO river guardians in recent years has declined. In 1995, actual observed catches and effort accounted for only $35 \%$ of the total (observed + estimated) catches and effort. This was similar to 1994 when $30 \%$ of the total catches were actually observed (Mullins and Reddin, 1995) but was much lower than years prior to 1990 when $80 \%$ of the total catches were actually observed (Mullins and Claytor 1989). In 1991 and 1994, when catches on the Humber River were at their lowest level in recent years, there was little difference between the DFO and creel survey results. In contrast, it appears that in 1992, 1993 and 1995, when angling catches were higher, the greatest discrepancy occurred between the two estimates of catch at Big Falls. It appears that it is more difficult to obtain an accurate estimate of the catch by the traditional methods when catches are high than when catches are low. If this is true for other rivers then population sizes derived from angling catch statistics will be underestimated on these rivers.

The high effort on the Lower segment of the Humber River in 1995 and 1994 compared to the 1992-1993 mean was probably due to the increase in catches of large salmon on this section of the river indicating an increase in the abundance of large salmon.

The Petersen single census and Darroch (1961) stratified estimates of small salmon returns to the Humber River in 1995 were almost identical. While, there was some variation in recapture probabilities among the two recapture strata of the Darroch (Appendix 2), the mean of the Darroch recapture probabilities (0.19) was very similar to the overall angling exploitation rate ( 0.18 ). This was the result of pooling of several of the initial strata which was necessary for the Darroch estimator as a result of low numbers of tag recaptures in some strata. If the number of recaptures had been large enough to maintain the initial number of strata, the Darroch stratified estimate of small salmon returns would probably have been a more appropriate estimator than the single census estimate in 1995.

The increase in total spawning escapement on the Humber River in 1995 compared to 1994 was anticipated as a result of the increased spawning escapement in 1990 compared to 1989. However, the magnitude of the increase was much greater than the maximum value anticipated (Mullins and Reddin, 1995). This can be attributed to an increase in the smolt-adult survival in 1995. However, it may also be a function of the variability in the recruit to spawner relationship.

The current assessment of the status of the Humber River salmon stock is based on returns to the river in JuneAugust. While returns in June-August represent by far the majority, there is anecdotal evidence that a run of large salmon enters the river in the fall. There has been some discussion among angling organizations in recent months about a fall fishery on this stock component given that the status of the Humber stock in general appears to have improved.

The following points need to be kept in mind in this discussion:

1. Compared to estimates of the total salmon population size in pre-moratorium years, based on an assumed exploitation rate in the commercial fishery, returns to the river in post-moratorium years are still far below historical levels. 2. Based on the smolt age distribution of approximately $50 \%$ age- 3 and $50 \%$ age- 4 of adults sampled in 1994 and 1995, small salmon recruits from the first post-moratorium year-class (1992) will not return to the Humber River until 1997 and 1998 and large salmon recruits will not return until 1998 and 1999.
2. We have little or no information on either the abundance or the biology of salmon entering the Humber River in the fall. If the popular assumption is correct that these fish are primarily virgin large salmon, then they are indeed a unique stock component because large salmon that enter the Humber River in June-August are primarily repeat spawners.

Assuming similar angling exploitation in 1996 to that in 1995, the spawning escapement anticipated for 1996, based on trend analysis, will be below the target. However, with the high variability in recruitment already described, the spawning escapement in 1996 may be even higher than in 1995. Recruitment in 1995 was $77 \%$ above that anticipated based on the ratio of recruits to spawners in 1992-1994.

In a stock with a healthy spawning population it is suggested that points in the spawner-recruit relationship described in Fig. 15 should fall above and below the line in a $50: 50$ distribution. Also, the points should fall above the target spawning line which in the case of the Humber occurred in three years of four years (1992, 1993 and 1995) since the closure of the commercial salmon fishery. We conclude from this that the Humber River salmon stock, while being below target spawning in some years, is now in a position to increase in size.

## ACKNOWLEDGEMENTS

Funding for the 1995 assessment project was provided in part by grants from the Canada/Newfoundland Agreement for Salmonid Enhancement and Conservation to Mr. W. Tucker for the operation of the two tagging traps, and to the Humber Valley Development Association for conducting the creel survey at Big Falls. We are grateful for their continued support. And as always, the support of DFO Conservation and Protection staff in Corner Brook and Deer Lake is also greatly appreciated.

Figure 15. Relationship between 1SW salmon spawners and recruits on the Humber River, 1980-1995.

Appendix 1. Big Falls Creel survey instructions, 1995.

The creel survey at Big Falls is designed similar to a bus route. The clerk travels to one location, waits a fixed interval of time, then moves on to next site and waits required interval of time at second site, etc. For Big Falls, only two sites have been designated, therefore, the route is very simple.

The two designated stops on the survey route are near the boat landing spot (designated as "Boat") and at the stairs immediately upstream of the boat landing (designated as "Stair"). The standard waiting period at the "Boat" location is 4 hours ( 240 minutes) while the "Stair" stop period is 1 hour ( 60 minutes).

The day is divided into four time periods as follows:

$$
\text { A - 5:30 to } 10: 00 \mathrm{AM}
$$

B - 10:00 AM to 2:00 PM
C - 2:00 to 6:00 PM
D - 6:00 to 10:30 PM

At each stop the clerk will interview as many anglers departing as possible.
Critical data to be obtained and recorded by the survey clerk during interviews with anglers include:

1. number of hours fished (start time and end time),
2. number of grilse kept,
3. number of grilse released,
4. number of large salmon released.

Any grilse which are kept by the angler should be examined for the following critical features:

1. presence of external Carlin tag (green) - be sure to record number
2. if no tag is present on fish, examine for tagging scar, two holes immediately below the dorsal fin.
3. if time permits, collect fork length, whole weight, and scale sample (if present)

NOTE: It is most important to get accurate count of fish being caught, presence or absence of tags or tagging scars and hours fished. The collection of length, weight and scales is secondary.

The starting point of the survey and the time which the clerk spends at the very first stop may vary from day to day and period to period. The starting point and the duration of the initial stop are given on the schedule. The clerk is expected to work the duration of each time period and this may involve moving between the two interview locations several times.

For example, looking at the example schedule, we see that for June 13, 1991 a creel is to be conducted during the $10: 00$ to 2:00 PM period. Looking at the schedule, the starting point is location 'boat' at time 10:00. The clerk should be ready to start intercepting anglers at that time at the boat landing site. Note also that the clerk would spend 30 minutes there (from 10:00 to 10:30) at which time, the person would move to the other location, stair. The clerk will stay at stair for 1 hour (10:45 to 11:45 assuming that the travel time from the boat landing spot to the bottom of the stair is 15 minutes) and intercept departing anglers. At 11:45, the clerk leaves and moves to the boat landing again. Assuming that the walk takes 15 minutes, then the clerk would intercept anglers at the boat landing between 12:00 and 2:00 PM at which time the sampling for that time period is over.

Appendix 2. Tags available and tags returned from angling on the Humber River, 1995.
Tags available unadjusted for tag loss and tags returned unadjusted for reporting rate.
