# Biological Update for Haddock in Division 4TVW in 1995 

by

K.C.T. Zwanenburg

Marine Fish Division
Maritimes Region, Science Branch
Bedford Institute of Oceanography
P.O. Box 1006, Dartmouth

Nova Scotia, B2Y 4A2
'This series documents the scientific basis for the evaluation of fisheries resources in Atlantic Canada. As such, it addresses the issues of the day in the time frames required and the documents it contains are not intended as definitive statements on the subjects addressed but rather as progress reports on ongoing investigations.

Research documents are produced in the official language in which they are provided to the secretariat.
${ }^{4}$ La presente série documente les bases scientifiques des évaluations des ressources halieutiques sur la côte atlantique du Canada. Elle traite des problèmes courants selon les échéanciers dictés. Les documents qu'elle contient ne doivent pas être considérés comme des énoncés définitifs sur les sujets traités, mais plutôt comme des rapports d'étape sur les études en cours.

Les Documents de recherche sont publiés dans la langue officielle utilisée dans le manuscrit envoyé au secrétariat.

#### Abstract

From reported historical annual landings of as high as $55,000 \mathrm{t}$ (1965) and up to $20,000 \mathrm{t}$ from 1979 to 1987, this fishery was essentially closed in 1995 with reported total landings of just under 120 t . Most of these landings were from Divisions 4 VW by longline and otter trawl. The current size composition of this stock shows a relatively narrow range of length-classes.

With the removal of all fishing activity from the closed area in 1993 and a virtual closure of the fishery in 1994, exploitation has fallen to the lowest observed since 1970.

Under the assumption that the maturity schedules have not shifted, the present spawning stock biomass may be as low as 13,000 t.

There are indications that the 1993 and 1994 year-classes maybe of above average abundance. These year-classes must be protected to promote stock rebuilding. The reduced exploitation which has been achieved over the past two years, if maintained in the near future, may aid in this rebuilding process.

## RÉSUMÉ

De débarquements annuels historiques allant jusqu'à 20000 t entre 1979 et 1987 et pouvant atteindre 55000 t (1965), cette pêche a essentiellement été fermée en 1995, le total des débarquements signalés n'ayant pas atteint 120 t . La plus grande partie des prises ont été récoltées à la palangre et au chalut à panneaux dans les divisions 4 VW . La distribution courante des longueurs chez le stock indique une plage relativement étroite de classes d'âge.

Suite à l'arrêt complet des activités de pêche dans ces divisions en 1993 et la fermeture en fait de la pêche en 1994, l'exploitation de ce stock a chuté au plus faible niveau observé depuis 1970.

Si l'on s'en tient à l'hypothèse que les régimes de maturité n'ont pas varié, la biomasse actuelle de géniteurs pourrait n'atteindre que 13000 t .

Des indices portent à croire que l'abondance des classes d'âge de 1993 et 1994 pourrait être supérieure à la moyenne. Il faudrait les protéger pour favoriser le rétablissement du stock. La quasi-fermeture de la pêche pendant les deux dernières années, si elle se poursuit dans un proche avenir, pourrait étayer ce processus de rétablissement.

## Description of the Fishery to 1995

Landings averaged 26,500t per year from 1950 to 1969, 5,000t from 1970 to 1979: since then landings have ranged between 8,000 and 20,000 t until 1987. The nominal catches for 1987 through 1994, have been taken almost exclusively as by-catch in other groundfish fisheries operating in divisions 4T, 4V, and 4W, and totaled just 120t in 1995 (Table 1). The 1989 nominal catch has been left as provisional due to a large discrepancy between the haddock bycatches reported to NAFO by the former USSR and those reported by the International Observer Program (Zwanenburg, et al. 1994).

The year-round nursery ground closure (mainly Emerald and Western banks) imposed in 1987 still remains in effect. Throughout the 1987 and 1992 period fixed gear vessels were allowed to fish inside the closed area. In 1993 the closed area was closed to all fishing. Since 1987 the fishery has been regulated through a combination of by-catch restrictions and trip limits. In 1995, the fishery was severely restricted and limited to $10 \%$ by-catches in hake, cusk, and pollock fisheries, and to 200 lb trip limits in the restricted fixed gear 4 Vn cod fishery.

Until 1984, most of the catch from this stock was taken from Division 4W by large otter trawlers (OTBs, TC4 and TC5) in the spring. In 1984, Division 4W was closed to trawlers from May to December to prevent the capture of the abundant early 1980s year-classes. This caused a shift in the fishery to 4Vs. From 1984 to 1986, favourable catch rats resulted in an increase in 4Vs landings to the point where they represented $40-60 \%$ of total landings. Following the exclusion of mobile gear from much of Division 4W (as a result of the imposition of the closed area in 1987) landings in 4 Vs ranged from 1,500 to 2,500 t annually, however landings in this area have declined to just 35 t in 1994. Since 1987, landings in 4W increased five-fold (from 991 to 5,261t) due mainly to the development of the fixed gear fishery inside the closed area. In 1993, following the exclusion of all gears from the closed area, landings declined and totaled only $60 t$ in 1995. Landings in Division 4T and Subdivision 4Vn have been negligible since 1989 (Tables 1 and 2).

Given the severely restricted nature of the fishery in the last two years, it is difficult to compare the distribution of landings by gear type with those of previous years. From 1987 to 1993 the proportion of landings taken by trawlers has decreased from 60 to about $50 \%$. In 1995 trawler landings represent about one-third of the total. Longline landings have ranged from 21 to $63 \%$ over the period 1987 to 1993 and in 1995 they accounted for $61 \%$ of total landings. Seiner landings represented approximately $3 \%$ of the total landings in 1994 (Table 3). Most of the fishery occurred in the third and fourth quarters of 1995 (Table 4).

Consultation with inshore fishermen in 4W indicated that the inshore haddock landings have declined significantly in recent years. Although a steady decline in landings has bee noted over the past 15 to 25 years, declines in the past 3-7 years have been relatively precipitous. In addition to this decline in landings, many independent sources report a change in the 'migratory pattern' of the inshore haddock. In past years the haddock would 'come ashore' in waters westward of Country Harbour, Nova Scotia. These fish would then 'migrate' westward throughout the remainder of the summer and fall until the fishermen in the area stopped fishing when the fishery
reached Halifax Harbour and approaches. More recently it is reported that the haddock are coming onshore further westward each year, and that the numbers caught has declined substantially. All respondents indicated that these 'inshore haddock' are different from offshore haddock by virtue of colour, shape, taste, and general size composition (larger). We presently have no information by which to judge these observations, but it illustrates our general lack of understanding of inshore resources in general. Plans for cooperative work with the inshore industry to determine the relationship between inshore and offshore haddock are being developed.

The foregoing discussion was not based on recorded information, but rather comes from the memories of the fishermen participants.

## Sources of Uncertainty

The preceding estimates of landings do not incorporate estimates of misreporting by area, or nonreporting of catches as a result of dumping or discarding. Unquantified, anecdotal information suggests that such practices have been significant sources of error at a number of times in the past. some of these reports indicate that the amount of dumping and discarding has represented a significant portion of the total reported landings. The effects of these potential errors on catch estimates for the assessment of the status of this resource cannot presently be evaluated.

## Composition of the Catch

The age composition of the 1995 landings is not available. Serious concerns have been raised about the accuracy of the ages determined for haddock. A significant bias in the ageing of haddock appears to have been introduced in the early 1980s resulting in over-ageing of young fish in the early 1980s and a subsequent under-ageing of older fish in the late 180s and early 1990s. Resolution of this problem is presently underway through an age validation study and the establishment and implementation of verified and consistent ageing criteria. These studies have progressed to the point where agers are being trained using the newly established and verified ageing criteria. The bias introduced through the historical ageing process will require the reexamination of historical otoliths to revise previous estimates of catch-at-age. A schedule or reageing and of ageing backlogged materials from 1989 through to the present has been established, and it is projected that age structured analysis of this resource will recommence during the first half of 1997.

The sampling information available for the 1994 landings is given in Table 5. Landings at length for the haddock by-catch from the foreign small mesh gear fishery were estimated from International Observer Program (IOP) data. For landings prior to 1977 no IOP estimates of length-frequencies were available. In the absence of these data it was assumed that the length frequencies of these landings were similar to those observed in the July research surveys conducted in 4W in the same years (Zwanenburg, et al. 1994).

Estimates of landings at length for 1970-1995 are given in Table 6. Landings at length by the domestic fisheries were estimated using commercial groundfish samples stratified as for the
estimation of landings at age outlined in previous documents (see Zwanenburg 1989). The length composition of domestic landings from 1970 to 1978 were estimated as outlined in Mahon et al. (1984).

The landings at length for 1995 shows modes at $22.5,30.5,46.5$, and 52.5 cm (Figure 1). The modes at 22.5 and 30.5 cm were the result of catches by the silver hake fishery and likely represent fish from the 1994 and 1993 year-classes, respectively. Landings in all length classes were well below the long-term average (1970-1994).

## Sources of Uncertainty

These estimates of length composition of domestic landings do not take into account any at-sea modification to the size composition. There have been reports of discarding and high-grading that cannot be quantified with presently available information. Dumping would tend to result in underestimation of total landings while selective discarding is likely to result in underestimation of removals at the smaller length classes. The overall effects of these potential sources of error cannot at present be quantified.

The estimation of lengths at age and, therefore, the conversion of the landings at length to landings at age depend on the accuracy of the lengths at age used and the distribution of the sizes at any given age. The present estimates are taken from ageing data whose reliability is still being investigated.

## Commercial Catch Rates

The restrictive nature of this fishery since 1987 does not allow for a comparison of present catch rates to those of earlier years from directed fisheries. We do not consider that by-catch catch rates are representative of the abundance of this stock.

## Research Vessel Survey Results

Catch rates at length for the fall July Research Vessel (RV) survey time series (1970-1995) are given in Table 7.

## Summer Surveys

Survey catch rates for 1970-1994 (Figure 2) indicated that overall catch rates declined from 1983-1987 and then fluctuated. Since 1992, survey catch rates have been low and stable. Catch rates in the recruited size groups ( 36 cm and larger) have declined since 1984 (Figure 3). Catch rates of the size-classes representing new pre-recruits (less than 36 cm ) show peaks in the early 1980s and again from 1988 to 1991 with the incoming 1988 year-class. Catch rates of prerecruits again increased in 1994 with the incoming 1993 year-class. This resource is centred in Division 4W with much lower catch rates in subdivisions 4 Vn and 4 Vs (Figure 4).

The long-term average length composition (1990-1994) of Subdivision 4Vn shows modes at $20.5,32.5$, and 50.5 cm (Figure 5). Subdivision 4 Vn also has the largest mean modal length of the three areas comprising the stock area. It is likely that the 20.5 cm mode represents age 1 fish although we cannot rule out a significantly different growth rate for the haddock in 4 Vn relative to other parts of the stock area. If growth rates are similar throughout the stock areas, the interpretation of these fish being age 1 would be consistent with the age structured analysis presented in previous assessments. This indicated that the 4 Vn population is composed mainly of fish aged $4+$ and the age 0 fish have never been observed in the survey of this area. There are anecdotal reports of haddock spawning in inshore areas of 4 Vn in years past, however, we have no observations with which to judge these reports. There is no evidence of the large 1988 yearclass in 4 Vn . The overall catch rates at length in 4 Vn in 1995 remain well below the long-term mean.

The long-term mean 91970-1994) catch at length in 4Vs shows modes at $16.5,28.5$, and 42.5 cm (Figure 6). These modes are smaller in all cases than those observed in 4Vn. The modes at 16.5 and 28.5 cm probably represent fish aged 1 and 2, respectively. Overall catch rates at age were below the long-term average in 1995, however, these were above average catches at model lengths of 22.5 cm and 30.5 cm . Above average catch rates were also observed at lengths over 54 cm .

An above average catch rate at 24.5 cm was also noted in the 1994 survey of this area. This differs significantly from the historical average and probably represent the fish observed at 10.5 cm in 1993, likely the 1993 year-class. The above average catch rate at 30.5 cm in 1995 again represents the 1993 year-class.

Division 4W has traditionally been the centre of distribution of this resource as evidenced by the significantly higher catch rates observed there. Analysis of the long-term catch at length for 4W shows clear modes at $8.5,20.5$, and 32.5 cm (Figure 7). The 1995 catch rate at length shows slightly above average modes at 22.5 cm and at 30.5 cm which are likely the 1994 and 1993 yearclasses, respectively. Again we note a shift in the modal length of these cohorts relative to the historical patterns. At 24.5 cm in 1994, the 1993 year-class would have been growing relatively faster than the historical average ( 20.5 cm at age 1), while in 1995 it is near the long-term mean modal length of 32.5 cm . At 22.5 cm in 1995, the 1994 year-class is again showing increased growth rates relative to historical values. Both the 1993 and the 1994 year-classes are of somewhat above average abundance.

The distribution of catch rates at length for 4 VW as a whole (Figure 8) shows the relative abundance of the 1993 and 1994 year-classes relative to the long-term average.

## Sentinel Survey Results

A sentinel survey was carried out in October of 1995. The survey was a cooperative venture between DFO, Department of Human Resources Development, and the Fishermen and Scientists

Research Society who acted as the sponsor of the survey and whose members participated in the survey. A total of about 220 standardized long-line sets of a planned total of 300 were completed in the course of the survey. Sets were distributed throughout 4VW and stratified on the same basis used for the 4 VsW spring survey (Figure 9) with the addition of three inshore strata shoreward of the 50 meter isobath. The survey caught a total of just over $6 t$ of haddock (Table 8). The distribution of these catches was consistent with the distributional patterns of haddock determined from DFO trawl surveys (Figure 10).

The sentinel survey haddock length composition shows that the gear employed (Mustad \#12 circle hooks) retained less than $5 \%$ of haddock under 36 cm while the modal catch was at 42 cm (Figure 11). This indicates a very steep selection curve. It also shows that that survey will not provide estimates of incoming year-classes until they reach marketable size-classes.

The results of this single survey are insufficient to allow for conclusions regarding overall stock abundance.

We examined the relationship between bottom temperature and haddock catches for both the sentinel survey and the DFO July trawl survey. Two-way area analysis of haddock catch (numbers) and temperature (SPANS GIS) shows both the proportion of bottom area available at any given temperature and the proportion of that area that is occupied by haddock at any predetermined density. Results for the sentinel survey (Figure 12) show that haddock are being caught over increasing proportions of the area available at temperatures to a maximum of $7^{\circ} \mathrm{C}$. It also showed that haddock appeared to be caught at bottom temperatures that were least available in terms of the overall study area. Spatial analysis of the July survey gave qualitatively similar results (Figure 13) except that the July survey caught haddock more frequently at colder temperatures than did the sentinel survey. This may indicate that haddock do occupy a small proportion of these colder bottom waters, but that they do not feed and are therefore no vulnerable to long-line gear.

Analysis of these same data using the temperature weighted cumulative catch method developed by Perry and Smith (1994) show that for the sentinel survey haddock tend to fall below the ambient environmental temperature curve until $6.5-7.0^{\circ} \mathrm{C}$ and that the rate of accumulation of haddock catches is greater than the rate of temperature accumulation for temperatures of $4-8^{\circ} \mathrm{C}$ (Figure 14). For the July survey the rate of haddock catch accumulation is roughly similar to the temperature accumulation curve until about $5^{\circ} \mathrm{C}$ when haddock catches accumulate more rapidly (Figure 15).

These results indicate that haddock prefer to inhabit waters above about $4^{\circ} \mathrm{C}$ and that although they do occupy small proportions of colder bottom areas, as shown by the July survey results, they do not appear to feed there as evidenced by the results of the sentinel long-line survey.

## Biological Indicators

The size ranges of haddock in both commercial landings and surveys have narrowed since 1970 indicating small range of sizes (ages) in the population in recent years relative to the documented history of this resource. A reduction in size range can be indicative of reduced growth rate or of high exploitation rates.

The condition of haddock (plumpness) expressed as the average weight of a fish at 45 cm , has decreased by about $10-15 \%$ since 1970 (Figure 16). The decline has been most gradual in Subdivision 4Vs, while in Division 4W it declined rapidly during the early 1980s and recovered somewhat before continuing its decline through the early 1990s. Condition factor increases in both 4 Vs and 4 W in 1995. Long-term declines in condition factor can be indicative of a population under stress from either exploitation or a gradually degrading environment.

## Recruitment

The 1995 summer survey indicated that both the 1993 and 1994 year-classes were caught at rates above the 1970-1994 average (Figure 8). Catch rates of these size classes remained above average when compared to the more recent (1970-1994) average (Figure 17). Survey results also indicated that the 1993 year-class in particular was also of above average abundance in Subdivision 4Vs (Figure 6). The occurrence of a year-class in above average numbers in 4Vs is usually indicative of an abundant year-class.

It has been demonstrated that abundant year-classes are more widely distributed than weak ones. Spatial analysis of the 1993 and 1994 year-classes show that, at age $1(18-24 \mathrm{~cm})$ and moderate densities (greater than 50 fish per standard survey tow), they occupy a total area which ranks them well below the area occupied by the early 1980s year-classes, but that they are the most widely distributed year-classes since the large 1988 year-class (Figure 18). Spatial analysis of the 1993 year-class at age $2(28-32 \mathrm{~cm})$ shows that it occupied a larger area moderate densities then the 1988 year-class at the same lengths (Figure 19). These analyses indicate that the distributional patterns of the 1993 cohort in particular is consistent with that of a relatively abundant year-class.

Catches of haddock in the foreign small-mesh gear fisheries give another indication of incoming recruitment in that they catch fish at lengths which are not yet recruited to the domestic fishery (Figure 20). Comparison of both the 1994 and 1995 small mesh gear haddock catch rates at length to the long-term (1978-1993) catch rates in these fisheries indicate that the 1993 year-class was caught at slightly below average rates (Figure 21). It is somewhat problematic to compare the long-term catch rates to more recent catch rates since there has been both a gear change (introduction of the Nordmor grate in 1993) and the seaward relocation of the landward boundary of the small mesh gear box in 1995. Although it seems clear that these measures have had a significant impact on catch rates of haddock greater than 34 cm , their effect on catch rates of small haddock are as yet undefined.

## Spawning Stock Biomass

Earlier assessments of this resource indicated that the probability of producing a large year-class is related to the general level of spawning stock biomass (Mahon, et al. 1985). At a spawning stock biomass below $16,000 t$ the probability of producing an above average year-class is considered low. At present spawning stock biomass estimated from surveys is on the order of 13,000 t (Figure 22). This estimate was derived from survey catch rates at length converted to weight and assumed knife-edged maturity at 43 cm . If the maturity schedule of this stock has shifted to maturing at younger ages, these would obviously be underestimates of overall SSB.

## Prognosis

The overall abundance of this resource remains below the long-term average as indicated by the results of survey data. Spawning stock biomass, as indicated by the biomass of 43 cm and larger fish is presently low, however there are signs that moderate year-classes have been produced in recent years (1992-1994). These year-classes must be protected to promote stock rebuilding. The reduced exploitation which has been achieved over the past three years, if maintained in the near future may aid this rebuilding process by allowing fish to realize their full growth and reproductive potentials.

Figure 1. Length composition of 4 TVW haddock landings for the long-term (1970-1994) and for the two most recent years. Note the change in scale for 1994/95.

Figure 2. Mean catch per tow for haddock of all sizes in the July survey of NAFO areas 4 VsW .

Figure 3. Mean catch per tow for pre-recruits (less than 36 cm ) and recruited (greater than 36 cm ) size classes of 4 TVW haddock.

4VW Haddock
RV Mean Catch per Tow

Figure 4. Mean catchiper tow for 4TVW haddock (all sizes) by NAFO Division and Subdivision from summer research vessel surveys.

Figure 5. Long-term (1980-1994; bars) and recent (1995; line) catch at length for haddock in Subdivision 4 Vn . Results are from the summer (July) surveys.

Figure 6. Long-term (1970-1994; bars) and recent (1994 and 1995; lines) catch at length for haddock in Subdivision 4 Vs . Results are from the summer (July) surveys.

Figure 7. Long-term (1970-1994; bars) and recent (1994 and 1995; lines) catch at length for haddock in Division 4 W . Results are from the summer (July) surveys.

Figure 8. Long-term (1970-1994; bars) and recent (1994 and 1995; lines) catch at length for haddock in Divisions 4 VW . Results are from the summer (July) surveys.

Figure 9. Set locations for the 1995 4VsW Sentinel Survey. Stratification scheme was identical to the summer groundfish stratification with the addition of three inshore strata (less than 50 fm ).

Figure 10. Haddock catches (kg per set) realized during the 1995 sentinel survey.

Figure 11. Size frequencies of 4 TVW haddock caught by the 1995 sentinel survey relative to the size frequency of haddock caught in the standard spring and summer trawl surveys conducted by DFO.

Figure 12. Temperatures occupied by 4 VW haddock during the 1995 sentinel survey. The bars represent the total bottom area (square km) available in the survey area at the water temperature indicated. The lines represent the proportion of that available bottom area and temperature occupied by haddock at densities of less than 100 fish per standard set, and densities greater than 100 fish per set.

Figure 13. Temperatures occupied by 4VW haddock during the summer trawl surveys of 1990 through 1994. The bars represent the total bottom area (square km) available in the survey area at the water temperature indicated. The lines represent the proportion of that available bottom area and temperature occupied by haddock at densities of less than 100 fish per standard set, and densities greater than 100 fish per set.

Figure 14. Cumulative Distribution Functions for bottom temperature and haddock catch weighted temperature for the 1995 4VsW Sentinel Survey. The results show that haddock were caught in lower then expected numbers at temperatures below about 4 degrees $C$ and then accumulated relatively rapidly in temperatures between 4 and 8 degrees $C$.

Figure 15. Cumulative Distribution Functions for bottom temperature and haddock catch weighted temperature for the 1995 July trawl survey. The results show that haddock catches accumulated at approximately the same rate as ambient temperature until about 5 degrees $C$.

Weight of a 45 cm Haddock

Figure 16. Weight (g) of a haddock at a length of 45 cm for Subdivision 4 Vs and Division 4 W from $1970-$ 1995 as estimated from July research survey catches.

Figure 17. Long-term (1970-1994; bars) and recent (1995; line) catch at length for haddock in Divisions 4 VW . Results are from the summer (July) surveys.

Area Occupied at age1 (>50fish/tow)

Figure 18. Area occupied (squre km ) by 4 TVW haddock cohorts at lengths equivalent to age 1 and densities greater than 50 fish per standard tow during the July surveys (1970 to 1995).

Area Occupied by Age $\mathbf{2 ( 2 8 - 3 2} \mathbf{c m})$ at densities $\mathbf{> 5 0}$ per tow

Figure 19. Area occupied (square km ) by 4 TVW haddock cohorts at lengths equivalent to age 2 and densities greater than 50 fish per standard tow during the July surveys (1970 to 1995).

Figure 20. Size grequencies of 4 TVW haddock caught by the Cuban small-meshed gear silver hake fishery relative to the size-frequencies of haddock caught by the commercial fleets as a whole and relative to that observed for the summer research vessel surveys. All data are for 1995.

Haddock C/E in Small-mesh Fisheries

Figure 21. Catch rates at length for 4 TVW haddock in the small-meshed gear fishery; long-term (1978-1993) and recent years (1993, 1994).

Figure 22. Mature trawlable biomass as estimated from July research vessel surveys.
