${ }^{1}$ This series documents the scientific basis for the evaluation of fisheries resources in Canada. As such, it addresses the issues of the day in the time frames required and the documents it contains are not intended as definitive statements on the subjects addressed but rather as progress reports on ongoing investigations.
${ }^{1}$ La présente série documente les bases scientifiques des évaluations des ressources halieutiques du Canada. Elle traite des problèmes courants selon les échéanciers dictés. Les documents qu'elle contient ne doivent pas être considérés comme des énoncés définitifs sur les sujets traités, mais plutôt comme des rapports d'etape sur les études en cours.

Les documents de recherche sont publiés dans la langue officielle utilisee dans le manuscrit envoye au secrétariat.

#### Abstract

Both spring- and autumn-spawning herring are found along the west coast of Newfoundland (4R). These stocks are exploited from April to December mainly by large and small purse seiners and to a lesser extent by fixed gillnetters. The 1997 assessment indicates that their stock status is generally healthy. Relatively young year-classes are in abundance among both the spring- and autumn-spawning herring in the purse seine fishery, as well as in the research surveys, and a high proportion of very old fish still appear in the catch. The 1995 fall acoustic survey estimated the minimum abundance of herring available along the west coast at that time at approximately $84,000 \mathrm{t}$.

It is concluded that the current TAC of $22,000 \mathrm{t}$ of spring- and autumn-spawning herring would not appear to be excessive. Catches in recent years have been below this level due mainly to the closure of the St. George's Bay spring fishery and poor fishing conditions in the fall. The appearance of the strong 1990 year-class in the spring gillnet fishery in 1996 suggests that there is no longer a biological rationale for the continued exclusion of commercial fishing from St . George's and Port-au-Port Bays. It is recommended that the reopening of these bays to commercial fishing proceed with caution, with areas of known spawning activity remaining closed to intensive fishing. It is further recommended that fishing effort be spread out along the coast and throughout the year as much as possible to avoid directed fishing on any one local spawning component.

## Résumé

Les deux groupes de fraie de printemps et d'automne de hareng se retrouvent le long de la côte ouest de Terre-Neuve (4R). Ces stocks sont annuellement 'exploités d'avril à décembre principalement par les grands et petits senneurs et dans une moindre mesure, par les pêcheurs utilisant des filets maillants. L'évaluation de 1997 indique qu'en général ce stock est en bonne santé. On trouve en abondance dans les captures à la senne et dans les relevés de recherche des classes d'âge relativement jeunes chez les reproducteurs de printemps et d'automne. De plus, une grande proportion de poissons très âgés est encore présente dans les captures commerciales. Le relevé acoustique de l'automne 1995 a estimé à ce moment l'abondance minimum du hareng disponible le long de la côte ouest à approximativement $84,000 \mathrm{t}$.

Il a été conclu que l'actuel TAC de $22,000 \mathrm{t}$ de reproducteurs de printemps et d'automne n'apparaîtrait pas excessif. Les captures des dernières années ont été sous ce niveau dû principalement à la fermeture de la pêcherie du printemps de la baie Saint-Georges et des conditions difficiles de pêche de l'automne. L'arrivée de la forte cohorte de 1990 dans la pêcherie du printemps au filet maillant suggère qu'il n'y a plus de raisons biologiques pour interdire la pêche commerciale dans les baies Saint-Georges et de Port-au-Port. Il est recommandé que la réouverture de la pêche commerciale dans ces baies se fasse prudemment, tout en interdisant une pêche intensive sur les frayères. Il est de plus recommandé de répartir l'effort de pêche le long de la côte et au cours de l'année afin d'éviter de diriger la pêche spécifiquement sur une des composantes de fraie locales.

## Introduction

Within most of the distributional range of northwest Atlantic herring (Clupea harengus L.) including the west coast of Newfoundland (NAFO division 4R) we can find herring populations which spawn either in the spring (April to June) or in the autumn (July to October). In addition, within each seasonal-spawning population (or stock), there are local spawning populations (or components) associated with specific spawning areas. Examples of springspawning components can be found in St. George's Bay, Port-au-Port Bay and St. Paul's Inlet (Figure 1). These local components intermix throughout the distributional range of the population, although most evidence suggests that once an individual fish spawns with a given local spawning component, it will return to spawn with that component year after year (Blaxter 1985). A local spawning component can therefore be considered as the basic biological unit to be protected from overexploitation. Local spawning components are however not independent of each other, as recruiting individuals may not spawn with their parental spawning component, but may be adopted by another local component, either with the same or a different spawning season (McQuinn, 1997a). All the local components which together occupy a common geographic range, as delimited by their annual migration patterns, constitute the overall population (or metapopulation) which in turn defines the management area (McQuinn, 1997b).

In the NAFO division 4R management area, we are presently unable to determine to which local component an individual fish belongs when it is caught outside of the spawning season. The basic management unit has therefore been defined as the seasonal-spawning stock, which can be determined from the stage of gonad development. The major spawning areas for the spring-spawning stock are located at the southern end of the coast in and around St. George's Bay (4Rd) and Port-au-Port Bay (4Rc) although several other spawning sites are known along the coast towards the north. Mature herring arrive and spawn in these areas from the end of April to the middle of June before dispersing. Autumn spawning is concentrated mainly north of Point Riche (4Ra) from mid-July to mid-September (Figure 1). At other times of the year, these two spawning stocks are mostly found in mixed schools in either feeding or overwintering areas. The major feeding areas, i.e. off St. George's Bay in the spring, north of Point Riche and in the Strait of Belle Isle in the summer and off Bonne Bay in the fall, are associated with concentrations of copepods (red-feed) and/or euphausiids (krill) which are their main food items. Based on winter research survey data (McQuinn and Lefebvre 1995b), they are believed to overwinter in the deeper waters of the Esquiman Channel (Figure 2).

## Description of the Fishery

## Management Plan

Total allowable catches (TAC) have been in effect since 1977. Since 1981, $45 \%$ of the TAC has been allocated to the fixed gear sector and $55 \%$ to the mobile gear sector. In addition, the purse seine quota has been allocated proportionately among the half-dozen active vessels and the gillnet allocation has been divided evenly between the regions north and south of Cape St. Gregory. Since 1989, an additional inshore allocation has been made for the small-purse-seine fishery. The
allocation for this gear sector has come from the inshore (fixed gear) quota and was increased from 2,000 to 4,800 t from 1989 to 1994.

Since 1987, the advised target fishing level has been exceeded only in 1991 (Figure 3). In 1994, a cap of $5,400 \mathrm{t}$ of spring spawners was imposed as a conservation measure for the St . George's Bay component of the spring-spawning stock. In 1995, this spring-spawner cap was lifted, in favour of a delayed opening (June 15) of St. George's Bay and Port-au-Port Bay to fishing to protect these local spring-spawning components in accordance with the recommendations of the west coast Herring Co-management Group (McQuinn and Lefebvre, 1995a).

## Total Catches

Since 1986, total herring landings from the west coast of Newfoundland averaged $17,300 \mathrm{t}$ (from $12,400 \mathrm{t}$ to $26,400 \mathrm{t}$ ) as compared to an average of $14,100 \mathrm{t}$ for the previous decade (Table 1; Figure 3). In 1996, total landings were limited to $14,700 \mathrm{t}$ due mainly to the closure of the St. George's Bay spring fishery, and to poor fishing conditions in the fall (e.g. herring close to bottom and high winds).

Herring catches in western Newfoundland are taken mainly by large ( $>85^{\prime}$ ) and small ( $<65^{\prime}$ ) purse seiners and to a much lesser extent by fixed gillnetters from April to December on both spawning and overwintering concentrations. Between 1988 and 1995, 90 to $98 \%$ of the total catch was taken by the purse seiners (Figure 4). This proportion dropped to $83 \%$ in 1996 due to a more active summer gillnet fishery.

## The Purse Seine Fleet

From 1984 to 1987, up to $80 \%$ of catches from the large purse-seine fleet were taken from October to December on over-wintering concentrations of herring in areas 4 Rb and 4 Rc (Figure 5a). In 1988, the development of an over-the-side market to Russian vessels contributed to a considerable increase in landings in the spring fishery in the St. George's Bay/Port-au-Port area from approximately $2,000 \mathrm{t}$ in 1987 to $16,000 \mathrm{t}$ in 1991 (Table 2a). This spring purse-seine fishery accounted for over $70 \%$ of the total catch in 1990 and 1993 (McQuinn and Lefebvre 1996a). This proportion has diminished to below $40 \%$ since 1994 when St. George's and Port-auPort Bays were closed to commercial fishing during the spawning season. Annual landings from small purse seiners have ranged between $2,800 \mathrm{t}$ and $3,800 \mathrm{t}$ since 1993 (Table 2b).

In 1996, purse seine fishing was concentrated around Port-au-Port Bay in May (Figure 6). Fishing activity then moved northward towards the Bay of Islands in June as in 1994 and 1995 (McQuinn and Lefebvre 1996a), as well as around Bonne Bay. In the late fall (September to November) herring schools were dispersed, as has been seen in recent years, and fishing was much more spread out along the coast. As in 1994 and 1995, relatively good catches were again recorded in St. George's Bay in October.

## The Gillnet Fleet

The inshore gillnet fishery is predominantly oriented toward supplying bait for the active lobster fishery. Due to this limited market demand, reported landings from the fixed gear sector
have generally been below $10 \%$ of the total 4R landings since 1985 (Figure 4). Recorded landings from 1990 to 1994 ranged between only 140 and $840 t$ (Table 2c). There has been an improvement in sales in the northern areas in recent years which has increased the proportion of the catch from 4Ra (Figure 5b) as well as increasing the total landings from 1,700 t in 1995 to 2,300 t in 1996.

## Biological Characteristics

## Data collection and Analysis

Random samples covering most of the major commercial landings were collected by port samplers and by index gillnet fishermen (Annex 1). These samples were frozen and sent to the Maurice Lamontagne Institute (MLI) in Mont-Joli, Quebec for analyses (i.e. length, weight, gonad weight, maturity stage and age determination).

Individual herring were assigned as either spring or autumn spawners by relating the maturity stage, estimated from a gonadosomatic index model (McQuinn 1989), to the date of capture, using the 4R maturity cycle chart (McQuinn 1987a). In the case of immature fish, otolith characteristics were used as described by Cleary et al. (1982). Ages were determined from the otoliths by counting the number of winter rings for spring spawners and the number of winter rings plus one for autumn spawners (Cleary et al. 1982). All herring aged 11 years or more were aggregated into an $11+$ age-group. The catch at age was generated (CAT $\triangle$ AGE v1.0, Anon 1986) for spring and autumn spawners as described by McQuinn (1987b), weighing the age compositions by the corresponding landing as grouped in Annex 1.

Since 1994, it has become more and more difficult to distinguish these latter year-classes in the catch at age. This has lead us to suspect an error in the age attribution in the past couple of years. The distinction of the winter annuli seems to have degraded since 1992 or 1993 when these herring stocks were exposed to colder annual temperatures (Gilbert et al., 1996). In this respect, the length frequency data appear more reliable, and it is easier to follow the major yearclass with these data.

## Spawning Stock Proportions

The proportion of each spawning stock in the catches varies among areas and seasons, as well as between the inshore and the offshore, as shown by differences between the gillnet and purse seine samples. In the spring (May and June), herring schools fished by gillnets in and around the major bays in the south near the spawning beds are typically dominated by spring spawners (Table 3, Figures 6a,b). Gillnet catches in 4Ra were also dominated by spring spawners in June. This was also seen in 1995 and appears to confirm the presence of a previously unreported spring-spawning area. Autumn spawners are more prevalent in deeper waters outside of St. George's Bay or north of Cape St. George in 4Rc as seen in the purse seine catches (McQuinn and Lefebvre 1995b). In the summer and fall (July to September), catches are mostly autumn spawners towards the north around the major autumn-spawning grounds (Table 3, Figures $6 \mathrm{c}, \mathrm{d}, \mathrm{e}$ ) and are mixed in the southern regions (Table 4). In the late-fall purse seine fishery (October to December), catches are a mix of spring and autumn spawners, although again there is
a predominance of autumn spawners towards the north and spring spawners towards the south (Figures 6f,g,h).

Spring spawners have dominated the catch in every year since at least 1973 (Table 5), averaging $72 \%$ in numbers. This percentage increased to over $80 \%$ between 1988 and 1990 due to the active spring fishery in St. George's Bay, which exploited mainly spring spawners nearshore (Table 4). With the closure of St. George's Bay to commercial fishing in 1994, the percentage of spring spawners in the total catch has since decreased to between 50 and $60 \%$.

## Age Composition of the Catch

From the mid-1980's, the 1980 and 1982 spring-spawner year-classes supported the fishery (Table 5) and are still important contributors to the total catch (Figure 7). In 1991, the 1987 year-class recruited strongly to the purse seine fishery (Table 6). In 1995, the 1990 yearclass recruited strongly to the overall spring-spawner catch (Figure 7) although more so in the north than on the southern spawning grounds. In 1996, the 1990 year-class dominated the purse seine catch, although the 1987 and older year-classes were still present. Biological samples supplied by the index fishermen revealed that the 1990 year-class was also present for the first time in the gillnet catches inside of St. George's Bay and Port-au-Port Bay in the spring of 1996. Recruiting year-classes are always seen 1-3 years later in the gillnet fishery than in the purseseine fishery due to the different gear selectivities.

Since 1983, the 1979 autumn-spawning year-class has been the most important contributor to the fishery from this stock and is still a dominant year-class in 4Ra (Figures 6d,e). Since 1990, the 1986 year-class has strongly recruited to the autumn-spawner purse-seine catch (Table 6), but only became a significant contributor to the gillnet fishery in 1992 (McQuinn and Lefebvre 1996a). The 1988 and 1990 year-classes have also contributed significantly to the total autumn-spawner catch in recent years (Figure 8). These three year-classes have gradually increased in importance in the gillnet fishery since 1993.

## Biological Condition

The overall condition factor, CF, of west coast of Newfoundland herring in the fall, as measured by the equation:

$$
C F=\frac{W_{S}}{L_{T}{ }^{3}} \cdot 10^{7}
$$

where $\mathrm{W}_{\mathrm{S}}$ is somatic weight $(\mathrm{g})$ and $\mathrm{L}_{\mathrm{T}}$ is total length (mm), showed a major decrease in 1993 and 1994 (Figure 9), corresponding with a general decrease in annual water temperatures noted for the northern Gulf of St. Lawrence. However, when put into the context of the last 27 years, average condition was much lower from 1973 to 1976. In 1995 and 1996, overall condition rebounded, although the recovery of the autumn spawners was somewhat less than for the spring spawners.

## Abundance Indices

## Acoustic Surveys

The 1995 acoustic survey estimated a minimum biomass of $84,000 \mathrm{t}(38,000 \mathrm{t}$ of spring spawners and $46,000 t$ of autumn spawners) with $64 \%$ of the herring biomass being surveyed in the two northern most strata (McQuinn and Lefebvre 1996b). The distribution of herring in the remaining strata was similar between 1993 and 1995, even though the survey was conducted three weeks earlier in 1995.

## Index-Fisherman Logbook Data

Abundance indices were estimated for both spring and autumn spawners from detailed logbooks of daily catch and effort compiled by index gillnet fishermen since 1984 (Tables 7 and 8) and standardized using a multiplicative model (Gavaris 1980). The categorical variables for this model were year, month and fishing area, and were chosen to account for spatial and temporal variability (Tables 9 and 10). Prior to these analyses, catches were proportionately allocated to spring and autumn spawners using the percent spawning-stock composition as determined from the commercial samples (Table 4). Most of these fishermen set their nets in the vicinity of either the major spring-spawning sites in the St. George's Bay/Port-au-Port area (McQuinn and Lefebvre 1995a) or the autumn-spawning areas north of Point Riche.

The standardized spring-spawner catch rates for St. George's Bay and Port-au-Port indicated that the 1987 year-class was above average, but not sufficiently abundant in these southern bays to rebuild these local spawning components given the heavy fishing effort exercised on them in the early 1990s. In 1996 this catch-rate index increased for the first time since 1992, simultaneous with the recruitment of the 1990 year-class to this fishery (Figure 10, Table 11). The next year or two will indicate whether the recruitment of this year-class will be strong enough to rebuild these components.

The 1986 autumn-spawning cohort appeared quite strong in the index-fisherman catch rates in 1992 and seemed at that time to be well above the 10-year average (Figure 11, Table 11). However, it declined sharply from 1992 to 1994 and stabilised at a low level. Although this catch-rate index seemed to reflect the strong recruitment of the 1986 year-class, its sharp decline was unexpected given the low fishing effort on the autumn-spawning stock. In addition, the recent recruitment of the 1988 year-class has not been reflected in the index, which puts in doubt its usefulness as a measure of abundance. It is possible that this index is more a reflection of a change in availability, since it is known that autumn herring spawn farther offshore and are less available to inshore fixed gear than are the spring spawners.

## Questionnaires

Comments collected from written questionnaires sent to all licensed inshore herring fishermen in 4R (Table 12) as well as from our index fishermen indicated some improvement in spring-spawning stocks in Port-au-Port Bay although it was felt that spawning activity had not yet improved significantly in St. George's Bay. There were also comments to the effect that the spring-spawning stock had improved in the Bay of Islands (Figure 12). The 1990 year-class,
which has been captured in the fall gillnet fishery since 1995, has started to spawn in these southern bays (Figure 6a,b). These observations are consistent with the catch rate data from index-fishermen in these areas (Figure 11).

North of Point Riche in 4Ra, the general opinion is that the abundance of herring is average to good especially in the summer and fall (Table 12), although along the Quebec shore comments indicated that the stock was in decline (Figure 11). Spawning in the fall was noted mainly south of Ferolle Point, and near Eddies Cove East.

## Discussion

The present assessment indicates that the status of the west coast of Newfoundland herring stocks is generally healthy. Relatively young year-classes are in abundance among both the spring- and autumn-spawning herring in the purse seine fishery, as well as in the research surveys, and a high proportion of very old (16-17 years) fish still appear in the catch. The fall 1995 acoustic abundance survey indicated a minimum total stock biomass of approximately $84,000 \mathrm{t}$ in October-November of 1995 , with $38,000 \mathrm{t}$ of spring-spawning ( $45 \%$ ) and $46,000 \mathrm{t}$ of autumn spawners ( $55 \%$ ).

## Spring Spawners

The 1990 spring-spawning year-class, which has been an important component of the purse seine catch since 1994, has now recruited to the gillnet fishery, including the southern spawning areas. The spring-spawner catch rates increased between 1995 and 1996, suggesting that the mature biomass in the southern spawning grounds had improved, primarily due to the recruitment of the 1990 year-class. Comments received from index fishermen and from the written questionnaires suggest some improvement in abundance over 1995 in Port-au-Port Bay, although with limited improvement in St. George's Bay. Continued improvement is expected as the 1990 year-class becomes fully recruited to the gillnet fishery. In addition, older year-classes (1980, 1982 and 1987) are still present in both the purse seine and gillnet catches, indicating a relatively low overall fishing mortality.

## Autumn Spawners

The autumn-spawning stock has historically received less fishing effort than the spring spawners (less than $28 \%$ of the total catch) since it occurs more in the northern areas farther from the principle landing ports. This has resulted in a wide age distribution in this stock, where in some areas the 1979 year-class is still dominant. The sharp decline in the logbook catch-rate data in 1992 is in contradiction with other indices which show this stock to be in relatively good condition: (1) the fall acoustic survey estimate of at least $46,000 \mathrm{t}$, (2) the light exploitation of this stock over the past decade, and (3) responses to a written questionnaire indicating that the situation with this spawning component along the Newfoundland shore north of Point Riche is relatively good. It is quite possible that the index-fisherman catch-rate series has become less reliable due to (1) a decrease in participation in the program (three to four logbooks annually
since 1992) and (2) the decrease in availability to inshore gillnets as the herring have moved farther offshore (McQuinn and Lefebvre 1994).

## Prognoses

The present analyses of the available commercial and research data has allowed us to conclude that in general, fishing mortality on these stocks over the past 20 years has not been excessive and that status quo harvest levels would not likely exceed $\mathrm{F}_{0.1}$. However, the concentration of fishing in the early 1990's in the southern bays did harvest disproportionately more spring spawners from this local component and resulted in a sharp decrease in its abundance. The closure of these bays in 1995 had the desired affect of concentrating fishing on the autumn spawners outside of St. George's Bay, of decreasing the quantity of spring spawners in the total catch and of allowing these fish to spawn undisturbed.

## St. George's Bay/Port-au-Port Bay

The strong recruitment of the 1990 year-class to the purse seine fishery since 1994, and its appearance in the spring gillnet fishery in 1996 suggests that there is no longer a biological rationale for the continued exclusion of commercial fishing from St. George's and Port-au-Port Bays. However, the lessons learned from the reduction in abundance of spawning herring in St . George's Bay and Port-au-Port Bay underline the importance of protecting local spawning components from disproportionately high fishing effort. The conservation of each individual local spawning component ensures the continuation of the local fisheries dependent upon them and maintains the reproductive potential of the entire stock. It is recommended that the reopening of the closed areas proceed with caution, with no concentrated fishing on or near the spawning grounds. For this reason, areas of known spawning activity should remained closed to intensive fishing.

The fishery in St. George's Bay must continue to be watched closely. Although it is expected that the 1990 year-class will bolster these local components, it is nonetheless recommended that a harvest limit be imposed for St. George's Bay and Port-au-Port Bay to allow fishing to proceed in a prudent manner, and that the distribution and composition of catches from within these bays be closely monitored. The continuation and enhancement of the indexfisherman program in this area is essential for the monitoring of spawning activity and as a local abundance index.

The widespread appearance of the 1990 year-class in both the spring and autumn stocks in 1996, as well as the observation of an abundance of 2 year-old herring in the Bay of Islands in the late fall (Figure $6 \mathrm{~g}, \mathrm{~h}$ ) are encouraging signs for the medium term outlook of these stocks. It is therefore concluded that the current TAC of $22,000 \mathrm{t}$ of spring- and autumn-spawning herring could be maintained without exerting excessive fishing pressure on these stocks. However, to avoid a repetition of intensive fishing on any one local spawning component, it is recommended that fishing effort be spread out along the coast and throughout the year as much as possible.

## Acknowledgements

We would like to thank Jocelyne Hudon and Karine Kabasha for their diligent and expert assistance with the collection and compilation of much of the raw data. We would like to acknowledge the contributions made by the fisherman and port samplers (Jerry Lavers and Phil West) of the west coast of Newfoundland who provided us with biological samples, logbook and questionnaire information and many useful insights regarding the population dynamics of 4 R herring.
