¹ This series documents the scientific basis for fisheries management advice in Atlantic Canada. As such, it addresses the issues of the day in the time frames required and the Research Documents it contains are not intended as definitive statements on the subjects addressed but rather as progress reports on ongoing investigations.

Research Documents are produced in the official language in which they are provided to the Secretariat by the author.

¹ Cette série documente les bases scientifiques des conseils de gestion des pêches sur la côte atlantique du Canada. Comme telle, elle couvre les problèmes actuels selon les échéanciers voulus et les Documents de recherche qu'elle contient ne doivent pas être considérés comme des énoncés finals sur les sujets traités mais plutôt comme des rapports d'étape sur des études en cours.

Les Documents de recherche sont publiés dans la langue officielle utilisée par les auteurs dans le manuscrit envoyé au secrétariat.

Abstract

A fisheries management program was put into effect in 1978 to restore the declining Atlantic salmon stocks in Statistical Areas K and L. The impact which the restrictions had in the fisheries and spawning escapements are evaluated and the present status of the stocks in each river are assessed. The reduced seasons had the desired affect of reducing exploitation in the commercial and recreational salmon fisheries, and increasing the spawning escapement in most rivers. The increased angling effort in the shortened season negated some of the anticipated benefits to spawning escapement. The target spawning escapements were not met in Humber River, Serpentine River, Harry's River, Flat Bay Brook and Fischells Brook. There were low abundances of grilse and large salmon in all rivers in 1978 and 1979 respectively. It is projected that this will result in low returns of grilse in 1983 and large salmon in 1984.

Résumé

Un programme de gestion des pêches a été mis en oeuvre en 1978 dans le but de restaurer les populations déclinantes de saumon atlantique des zones statistiques K et L. Une évaluation est faite de l'impact des restrictions sur les pêches, sur les géniteurs et sur les stocks actuels de chaque rivière. La diminution des saisons de pêche a eu l'effet désiré. Il y eut au une réduction de l'exploitation du saumon par les pêches sportives et commerciales ainsi qu'une augmentation du nombre de géniteurs de plusieurs rivières. Ces résultats furent cependant amoindris par l'intensification de l'effort de pêche à la ligne au cours de la saison abrégée. Le nombre de géniteurs désiré n'a pas été atteint dans les rivières Humber, Serpentine et Harrys ainsi que dans les ruisseaux Flat Bay et Fischells. On enregistre de plus une faible remontée de castillons et de gros saumons en 1978 et 1979 pour toutes les rivières. Cette situation permet de prévoir des retours faibles de castillons en 1983 et de gros saumons en 1984.

Introduction

In 1978, Fisheries and Oceans imposed restrictions (Tables 1 and 2) on the commercial and recreational Atlantic salmon fisheries of Areas K and L (Fig. 1). Assessments conducted in the mid-1970's indicated that the catches in the commercial fishery and in the sport fishery on most rivers were declining (Chadwick et al. 1978). Of particular concern was the decline in large salmon and the apparent decline in egg deposition. The following evaluates the impact of restrictions on the fisheries and assesses the present status of the stocks in Areas K and L. Fisheries management advice which was put forth by CAFSAC is in CAFSAC Advisory Document 83/7.

Methods

The impact of the 1978-82 salmon management program in Areas K and L was assessed by comparing egg depositions during the five years (1978-82) to target spawning requirements for each Area and river system and by examining trends in catch and effort in commercial and recreational fisheries.

Target spawning requirements for each river system were calculated using an egg deposition of 240 eggs per 100 m² of parr rearing area (Elson 1975) and an estimate of the number of eggs deposited per spawner (Table 3). The latter was calculated using a fecundity of 1540 eggs per kilogram as used in Atlantic Salmon Task Force Review (Anon. 1978) and mean values of sex ratio (percentage females) and weight for grilse sampled in the recreational fishery (unpublished data). Biological characteristics of large salmon were taken from samples in the commercial fisheries. The proportion of grilse and large salmon were taken from mean recreational harvests (1973-77) in Moores et al. (1978). Biological characteristics of salmon from the Little Codroy River and Highlands River were obtained from samples at fish counting fences (Murray 1968; Chadwick, unpublished data; respectively). Estimates of the amount of parr rearing habitat (Table 3) in each river was obtained from stream surveys (Anon. 1978).

Egg depositions during 1978-82 were calculated with two assumptions: 1) mean harvests in the recreational fishery during this period were proportional to spawning escapements (Chadwick 1982), and; 2) additional spawners would be available because of reduced fishing seasons. Angling exploitation rates were not available for stocks in Areas K and L, therefore, a range in spawning escapements were calculated using exploitation rates of 20% and 40% (Table 4), these are considered the minimum and maximum observed values for rivers in insular Newfoundland (Chadwick 1982).

Additional spawners (Table 4) were assumed to be available from season reductions in three fisheries: the recreational fishery in Areas K and L; the commercial fishery in Areas K and L; and the commercial fishery in Area J. In the recreational fishery, additional spawners (large salmon and grilse) (Table 5) were calculated by river system as the difference between harvests in reduced and full seasons for the years 1973-77. Additional spawners in the commercial fishery were calculated for Areas J, K, and L using the same technique; there were also no significant changes in fishing effort in these fisheries. Interception of mainland stocks in Area J were assumed to be 65%

(Pippy 1982). Spawners were divided among river systems in proportion to the mean 1973-77 recreational harvest. Because these additional spawners differed in biological characteristics from fish used to calculate spawning requirements a ratio was developed to convert the additional spawners to the equivalence of fish in spawning requirements (Table 6). This was based on eggs/spawner.

Trends in catch and effort were examined in historical data from both fisheries; adjustments were made to landings in the recreational fishery to account for season changes.

Results and Discussion

Area L

The catch statistics for the commercial salmon fishery in Area L are shown in Table 7 and Fig. 2. The mean catches of large salmon 1973-77 and 1978-82 are 5.0 t and 4.4 t respectively. The 19% difference between the means was not significant. The mean catch of small salmon (1SW) increased by 85% from 5.2 t in 1973-77 to 9.6 t in 1978-82. The increase is not statistically significant due to the large variance and small number of years. The catch per licensed gear unit increased by 66% from 35 kg/unit to 58 kg/unit. Although no overall statistical differences can be demonstrated, the data do suggest an increase in abundance of both large salmon and 1SW salmon available to the commercial fisheries 1978-82. Particularly, when one considers that the catches in 1978-82 occurred during a period with reduced commercial fishing season and licensed gear units.

There was no significant difference in the mean angling catches of grilse and large salmon in 1973-77 and 1978-82 (Tables 8 and 9, Fig. 3 and 4). However from 1978-82 the angling effort remained relatively constant, whereas there was a gradual increase in total catch and CUE during this period. This suggests increasing abundance of fish in the rivers 1978-82. But it could also be due to additional exploitation on fish release from commercial fisheries.

The linear relationships tested for catches of grilse and large salmon in the recreational and commercial fisheries of Area L are listed in Table 10. The angling catch of grilse (1SW salmon) in Area L (1978-82) was significantly correlated ($P < 0.05$) to the commercial catch of grilse during the same year in Area L, and the commercial catch of large salmon in Area L (1978-82) was significantly correlated ($P < 0.1$) to the commercial catch of large salmon during the same year in Area K. Since these correlations are positive, it can be inferred that if there is a change in catch of grilse in the commercial fishery, there will be a corresponding change in the grilse catches in the angling fishery in Area L. Similarly, if there is an increase or decrease in commercial catch of large salmon in Area K, there will also be a corresponding change in the commercial fishery of Area L. Although it is suspected that these fisheries are exploiting the same stocks, it cannot be concluded from these analyses.

Humber River

The unadjusted and adjusted angling catches of Atlantic salmon in the Humber River are shown in Tables 11 and 12 and Fig. 5 and 6. It appears that the shortened angling season had a negligible influence on catch. Average catches of large salmon and grilse declined by only 11% and 4% respectively (Fig. 6). The average angling effort, 8265 rod days, for 1978-82 is about 8% less than in the previous five years. This can only be partially explained by the reduced season. The recorded effort in 1977 was only 6127 rod days which is the lowest recorded since 1968. There has been a gradual increase in the angling effort since 1977. A gradual increase in the catches (Fig. 6) of grilse has resulted in a steady increase in catch per rod days from 0.38 in 1977 to 0.50 in 1982 (Fig. 5). The catches of grilse, 1980-82, although less than the peak catches of 6147 and 5102 in 1975 and 1976, are similar to the catches in the mid-1960's and early 1970's. There was considerable annual variation in the catches of large salmon, 1978-82, with less than 100 fish caught in 1979 and 1982 (Fig. 6). Although there seems to have been some improvement in the abundance of large salmon 1978-82, over the abundance in 1974-77, the mean catch of 153 salmon in 1978-82 is 30% less than the mean catch 1963-67 and 55% less than the mean catch 1968-72. It is anticipated that there will be a decrease in abundance of both grilse and large salmon in 1983 and 1984 due to the apparent low abundance of spawners in 1977 and 1978. The target spawning escapement is 18,452 fish (Table 3). The maximum estimate of spawners, 1978-82 indicates a deficit of 458 fish; the minimum estimate, however, indicates a deficit of 9,838 fish (Table 4). Thus, it would appear that spawning requirements are not being met on Humber River.

Hughes Brook and Cook's Brook

The target spawning requirements in Hughes Brook and Cook's Brook are 215 and 357 respectively (Table 3). The unadjusted recorded angling statistics for Hughes Brook and Cook's Brook are shown in Tables 13 and 14. There has not been a legal sport fishery on either stream since 1977. No data are available to assess the spawning escapements or to project returns.

Serpentine River

The angling catch statistics for Serpentine River are shown in Tables 15 and 16, and Fig. 7 and 8. Prior to 1966, the angling catch on Serpentine River comprised of about 40% large salmon (Table 15). Subsequent to 1966 the mean percentage of large salmon (by smolt class) was 15%; in only two years did the proportion of large salmon exceed 30%. The total numbers of large salmon have drastically declined since the mid-1960's when an average of 151 large salmon (1963-67) were caught annually, to the mid-1970's when an average of only 17 large salmon (1973-77) were harvested annually. There was no significant increase in the mean catch of large salmon 1977-82 over 1973-77. Since there was no significant increase in fishing effort (Fig. 7), it would appear that the abundance and thus spawning escapement of large salmon has not increased during the period 1978-82. The mean angling catch (165) of grilse during 1978-82 is significantly ($P < .05$) higher than the angling catches in the previous five years (Table 16, Fig. 8). This suggests an increase in abundance

and spawning escapement during 1978-82. However the 5-year mean, 1978-82 is still less than the mean catch of 232 observed in 1963-67.

It would appear that spawning escapements on Serpentine River are inadequate for optimal egg depositions. The maximum estimate of egg deposition 1978-82 indicates a deficit of about 1200 spawners; the minimum estimate would suggest that the shortage is greater (Table 4).

Fox Island River

The angling catches of Fox Island River are summarized in Table 17 and Fig. 9. The river was closed to angling 1976 to 1980 inclusive. Catches during the reduced season suggest an improvement in stock abundance.

Area K

The catches of Atlantic salmon in the commercial fisheries in Area K are shown in Table 18 and Fig. 10 and Statistical Area J and Sections 38 and 39 are presented in Table 19. The catches in the angling fisheries in Area K are shown in Tables 20 and 21 and Fig. 11 and 12. Data are not available on the proportion of large and 1SW salmon in the commercial fishery prior to 1969. Although the greatest total catch (59 t) in the commercial fisheries in Area K occurred in 1970 (Table 18), there has been a gradual decline in abundance from 1956 to 1975 (Fig. 10).

The mean total commercial catch of 25.6 tonnes during 1978-82 is not different from the 25.0 tonnes harvested during the equivalent fishing period 1974-77 (Table 18). This suggests that the overall abundance of salmon available to the commercial fishery June 1 to July 1, 1978-82 was similar to that available during the same period (June 1 - July 10) in 1974-77. If the reduction in licensed gear (1978-82) had a corresponding impact on fishing effort then it is possible that the abundance of salmon would have been higher during the fishing season, 1978-82. Nevertheless, it would appear that the restrictions on the commercial fisheries did allow additional salmon to enter the rivers. By taking the mean of the differences between the catch in the full season and the partial season each year 1974-77 and calculating 95% confidence limits, the total weight of fish escaping the commercial fishery 1978-82 was calculated to be 7.5 ± 3.8 tonnes. Considering 1SW and large salmon separately, the weight released would be 2.5 ± 2.1 tonnes 1SW salmon and 5.0 ± 2.2 tonnes of large salmon.

A number of correlations between harvests of large salmon and grilse were tested in the commercial and recreational fisheries (Table 22). The angling catches and commercial catches of large salmon (1969-82) in Area K in year n were positively correlated ($P < 0.05$). The commercial catch of 1SW salmon in Area K was positively correlated ($P < 0.05$) to the commercial catches of 1SW salmon in Statistical Section 38 (1978-82). The commercial catches of large salmon and of 1SW salmon in Area K + L were positively correlated ($P < .05$) to the commercial catch of large salmon and of 1SW salmon ($P < .01$) in Section 38 + 39. Also the commercial catch of 1SW salmon in Area K + L (1978-82) was positively correlated ($P < .05$) to the commercial catch of 1SW salmon in Section 39. These analyses indicate that the commercial fisheries in Areas K,

L and Sections 38 and 39 are harvesting the same stocks. This supports the findings of previous tagging studies (D. G. Reddin, Personal Communication).

The angling catches of large salmon and grilse peaked in 1963 (2240 fish) and in 1964 (8956 fish) respectively (Table 20, Fig. 12). Subsequently, there was a progressive decline in catches of both sea-age groups of salmon. From 1961 to 1976, the angling effort increased by 106% from 10,200 to 21,700 rod days. Table 21 presents a summary of angling catch statistics 1973-1977 adjusted to the seasons in effect during 1978-82. The mean number of rod days in the adjusted 1973-77 period (Table 21) is 12,840 which is not significantly different from the mean rod days for 1978-82 (Table 20). This suggests that the reduction in fishing effort observed from 1978 to 1982 resulted from the reduction in season (Fig. 11). The increased angling effort in 1981 and 1982 could have reduced the intended benefits from the season reductions during those years. The mean catch of large salmon in the partial angling season 1973-77 is 434 fish which is 47% less than the mean catch of large salmon during the full season (Tables 20 and 21). The mean catch of grilse in the partial season (1973-77) is 3,814 which is about 20% less than the catch during the full season. The mean catch of grilse (3814) and large salmon (465) during 1978-82 is not significantly different from the mean catch of grilse (4130) and large salmon (434) caught during the partial season 1973-77. This suggests that the average abundance of fish available to the angler during the reduced season 1978-82 was at least as great as in the previous five years. Thus it is apparent that the early run fish that were released from the commercial fishery were, for the most part, able to pass upstream to the headwater fish sanctuaries before the angling fishery opened. If one assumed that the average population size 1978-82 was similar to the average population size 1973-77 (which is supported by the commercial catch statistics) then the average number of fish released from the angling fishery can be estimated by calculating the mean difference between the full season and the partial season during 1973-77. The number of fish released would be 379 large salmon \pm 113 (95% C.L.) and 1069 grilse \pm 473.

Harry's River

The salmon angling catches for Harry's River 1953-82 are presented in Table 23 and Fig. 13 and 14. The angling catches for 1973-1977, adjusted to the July 1-August 15 season of 1978-82 are shown in Table 24 and Fig. 13 and 14. The mean five year catch of large salmon has declined by 79% from 331 in 1963-67 to 71 in 1973-77. The mean catch of grilse declined during the same period by 33% from 1528 to 1028. It is apparent from Fig. 14 that the downward trend of catches of large salmon seems to have levelled off at a very low abundance and that the numbers of grilse continue to slowly decline. The mean number of rod days and catch of grilse and large salmon 1978-82 is not significantly different from the mean effort and catches during July 1 - August 15, 1973-77 (Table 24).

The target number of spawners for Harry's River is 4911 fish (Table 3). Using the most optimistic scenario where all fish released from the commercial fisheries passed upstream and were not available to the recreational fishery, and exploitation in the recreational fishery was 20%, there would have been a surplus of 177 spawners (Table 4). The more pessimistic scenario predicted an

average spawner deficit of 1218 fish. Since there was no apparent increase in egg deposition in Harry's River during 1978-82, an increase in escapements over the next five years is not anticipated.

Southwest and Bottom Brooks

The angling catch statistics for Southwest and Bottom brooks are presented in Tables 25 and 26 and Fig. 15 and 16. The fishing effort on Southwest and Bottom brooks remained relatively constant at between 2000 and 3000 rod days between 1964 and 1974. In 1975 the effort increased to 6700 rod days, but quickly dropped to 3450 in 1977. A further reduction to a mean of 1380 rod days occurred in 1978-82, due to the shorter angling season (Table 25 and Fig. 16). The catch per rod day declined from 0.67 in 1958-62 to 0.22 fish per rod day in 1973-77. An improvement in CUE is apparent in 1980, 1981, and 1982, suggesting improved escapement to the river (Fig. 16). Figure 15 suggests that the abundance of large salmon has continued to decline from 1974 to 1982 whereas there was improvement in the abundance of grilse from 1980 to 1982. The catches of grilse suggests that their abundance is as high if not higher than during the early 1960's. Reports from field staff suggests that the abundance of large salmon could be higher in 1981 and 1982 due to early runs which permitted the fish to move to fish sanctuaries prior to opening of the angling season. Both estimates of spawning escapements indicate a surplus of spawners (Table 4).

It is concluded that there has been an overall improvement in the spawning escapement resulting from the reduced seasons, however no increase in escapements are expected in 1983 and 1984 due to low spawning escapements in 1978 and 1979.

Little Barachois Brook

Angling catch statistics are shown in Table 27 and 28 and Fig. 17 and 18. There has been a decline in CUE from 0.65 in 1972 to 0.31 in 1977 (Table 27). During this period the fishing effort increased by 300% and the catch increased by about 150%, although there was a decline in catches of large salmon (Fig. 18). It is also apparent from Fig. 18 that there has not been an improvement in spawning escapement during the period of season reductions and that exceptionally low spawning escapements occurred in 1978 and 1979. The maximum estimate of spawning escapement in 1978-82 indicates a surplus of 345 fish and the minimum estimate a surplus of 23 fish (Table 4).

There is an indication that due to the low egg depositions in 1978-79, the 1983 and 1984 spawning escapements will be lower than the 1980-82 mean escapements.

Flat Bay Brook

The angling catch statistics are presented in Table 29 and Fig. 19 and 20. The target egg deposition is 2905 fish (Table 3). From 1963 to 1972, the angling fishery had a mean annual catch of more than 1000 fish (Table 29). By 1975 the annual catch had declined to less than 500 fish. Although there was a reduced season on the sport fishery 1976-80, the 1981 and 1982 catches

(Fig. 20) do not indicate that there has been any improvement in the abundance of either large salmon or grilse. Table 4 indicates that there is a spawning deficit of between 251 and 1078 fish. It is also apparent from Table 29 that the escapements to the river were particularly low in 1978 and 1979. The progeny from the 1978 and 1979 spawners will be returning in 1983 and 1984.

Fischells Brook

The angling catch statistics are presented in Tables 30 and 31 and Fig. 21 and 22. Prior to 1967, the large salmon component of the escapement to Fishells River was greater than 25%. Since 1969 to 1977 there was noticeable decline in both the large salmon and grilse components (Table 30, Fig. 22). During the period of season restrictions (1978-82) there was an overall improvement in the angling catches, particularly the grilse component in 1980-82. In 1979, however, there was a poor return of both components.

Although there was an apparent increase in egg deposition, 1978-82, the estimated average spawning escapement showed a deficit between 268 to 850 spawners (Table 4). Under the present regulations, the stocks should make a slow recovery. If optimal spawning requirements are to be met more quickly, however, then a reduction in harvest will be necessary.

Robinson's River

The angling catch statistics are presented in Tables 32 and 33 and Fig. 23 and 24. A review of Fig. 23 and Table 33 shows a substantial increase in angling effort during the reduced season 1978-82. This may have negated some of the benefits which would have accrued from the commercial and recreational season reductions. Nevertheless, even though the angling effort increased there was an increase in total catch and in CUE, suggesting an increase in abundance of fish. It is also apparent from Table 33 and Fig. 24 that there was a progressive increase in the numbers of grilse and large salmon. The target spawning escapements is 1752 fish (Table 3). For the period 1978-82, the most optimistic approach to calculating spawning escapement suggests that escapements, on average, were exceeded by 2638 fish (Table 4).

As with other rivers, the escapement of grilse in 1978 and large salmon in 1979 was depressed. Thus, it is predicted that the abundance of grilse and salmon will be below average in 1983 and 1984 respectively.

Barachois Brook

Angling catch statistics for Barachois Brook are presented in Tables 34, 35, Fig. 25, 26. There has been a slight decline in fishing effort during the fishing period June 20 to August 31, and a decline in catch and CUE (Fig. 25 and Table 35). Of particular interest, is the catch of 0, 3 and 2 large salmon in 1979, 1981 and 1982, respectively (Table 34, Fig. 26). There has also been a progressive decline in catches of grilse in the adjusted season from 1973 to 1982. Although the catch statistics indicate a reduction in abundance of spawners during 1978-82, the field staff have observed large numbers of early run fish in the headwater sanctuaries of Barachois Brook which suggests that a direct assessment from the catch data may underestimate spawning escapements

(Table 3). Both estimates of average spawning escapement 1978-82, indicated a surplus of spawners (Table 4).

It is concluded that the status of this stock cannot be reasonably assessed due to the apparent early run of salmon. However, the catch data suggests particularly low escapements in 1978 and 1979 (as in other rivers) which will result in reduced returns in 1983 and 1984.

Crabbes River

The angling catch statistics for Crabbes River are presented in Tables 36, and 37, Fig. 27 and 28. There was a substantial decline in the numbers of large salmon and grilse from the early 1960's to 1977 (Table 36). An evaluation of the catch statistics (Table 37) for the angling period June 20-August 31, indicates that from 1978-82 there was a significant increase in mean fishing effort, catch per rod day and total numbers of fish. The increased catch was apparent for large salmon except in 1979 and for grilse except in 1978 (Fig. 28). The target spawning escapement is 2345 fish (Table 3). The estimated mean spawning escapements 1978-82 using the two scenarios are 1) surplus of 977 fish and 2) a deficit of 73 fish (Table 4).

The low spawning escapements in 1978 and 1979 will result in depressed abundance in 1983 and 1984.

Highlands River

Highlands River was closed to angling 1978-82. The angling catch statistics prior to 1978 are presented in Table 38. Fisheries and Oceans operated a fish counting fence on Highlands River in 1980, 1981, and 1982: the catches of large salmon were 55, 29, 56 respectively and grilse were 82, 127, 100 respectively. The target spawning escapement is 600 fish. Thus it would appear that the spawning escapements were less than 50% target levels.

Grand Codroy River

The angling catch statistics for the Grand Codroy River are presented in Tables 39 and 40, and Fig. 29 and 30. The target spawning escapement is 3511 (Table 3). There has been a continual increase in angling effort on Grand Codroy River 1953-82. The 1982 effort was 60% higher than the mean 1968-72 angling effort (Table 39). The catch of grilse has increased in response to the fishing effort and has remained relatively constant at just over 1000 fish except for 1977 and 1978 when only 773 and 510 grilse were angled respectively (Table 39 and Fig. 30). The angling catches of large salmon, except for 1979, have increased over the catches 1970-77 (Fig. 30 and Table 40). The CUE has followed a downward trend since 1976 (Fig. 29). For the period 1978-82, it would appear that escapements of grilse and salmon have remained constant (except for 1977-78) and the escapement of large salmon has increased slightly. Both estimates of spawning escapements for 1978-82 indicated a surplus of spawners. It is anticipated that the abundance of salmon will be less in 1983 and 1984 due to low abundance of spawners in 1978 and 1979.

Little Codroy River

A summary of the angling catch statistics for Little Codroy River is presented in Tables 41 and 42, and Fig. 31 and 32. The target spawning escapement is 463 fish (Table 3). During the period of restrictions, 1978-82, the angling effort remained relatively constant (Fig. 32, Table 42). The catches and CUE show considerable annual variability, which could have resulted from annual variations in timing of upstream migration or indicate a very unstable stock. There was only one year (1982) in which the catch of large salmon showed any improvement. Particularly low escapements were apparent in 1978 and 1980. Both methods of calculating the average spawning escapements indicate a surplus of spawners (Table 4). A comparison of the angling catches in the full season and during July 1-August 15 from 1970-77 suggests considerable annual variation in the timing of the run of large salmon and to a lesser degree grilse to the river. This supports the findings of A. R. Murray when he operated a counting fence on Little Codroy River. This provides further uncertainty in the accuracy of estimates of spawning escapements 1978-82.

1976	11838	246	3936	4182	0.35
1977	11801	588	3542	4130	0.35

Table 22. List of linear regressions calculated for harvest statistics in commercial and angling fisheries in Area K.

-
1. Angling catches of large salmon in Area K (year n) on commercial catches of large salmon (year n) in Area K
 1969-1982 $y = 0.0144x + 490.15$ $n = 14$; $R^2 = 0.31$ Significant at $P < 0.05$
 1978-1982 $y = 0.0270x + 223.33$ $n = 5$; $R^2 = 0.35$
 2. Angling catches of grilse in Area K (year n) on commercial catch of 1SW salmon in Area K (year n)
 1969-1982 $y = 0.0418x + 4132.27$ $n = 14$; $R^2 = 0.05$
 1978-1982 $y = 0.0909x + 2267.10$ $n = 5$; $R^2 = 0.11$
 3. Commercial catches of 1SW salmon in Area K on commercial catches of 1SW salmon in Section 39 (year n)
 1969-1982 $y = -0.0085x + 10680.33$ $n = 14$; $R^2 = 0.00$
 1978-1982 $y = 1.8428x + 12219.84$ $n = 5$; $R^2 = 0.64$
 4. Commercial catch of large salmon in Area K (year n) on commercial catch of large salmon in Section 39 (year n)
 1969-1982 $y = 0.0851x + 10680.33$ $n = 14$; $R^2 = 0.08$
 1978-1982 $y = 0.176x - 2666.61$ $n = 5$; $R^2 = 0.12$
 5. Commercial catch of large salmon in Area K (year n) on commercial catch of large salmon in Section 38 (year n)
 1969-1982 $y = 0.0743x + 12421.1$ $n = 14$; $R^2 = 0.02$
 1978-1982 $y = 0.4468x + 7679.45$ $n = 5$; $R^2 = 0.75$ Significant at $P < 0.01$
 6. Commercial catch of 1SW salmon in Area K (year n) on commercial catch of 1SW salmon in Section 38 (year n)
 1969-1982 $y = 0.1475x + 14757.01$ $n = 14$; $R^2 = 0.02$
 1978-1982 $y = 1.4045x + 12381.8$ $n = 5$; $R^2 = 0.84$ Significant at $P < 0.05$
 7. Commercial catch of 1SW salmon in Area K (year n) on commercial catch of 1SW salmon in Area J (year n)
 1969-1982 $y = 0.0922x + 12902.89$ $n = 14$; $R^2 = 0.21$
 1978-1982 $y = 0.3416x + 11125.05$ $n = 5$; $R^2 = 0.69$ Significant at $P < 0.1$
 8. Commercial catch of large salmon in Area K (year n) on commercial catch of large salmon in Area J (year n)
 1969-1982 $y = 0.0178x + 13146.19$ $n = 14$; $R^2 = 0.02$
 1978-1982 $y = 0.3144x - 20846.81$ $n = 5$; $R^2 = 0.51$
 9. Commercial catch of large salmon in Area K + Area L (year n) on commercial catch of large salmon in Section 39 + Section 38 (year n)
 1969-1982 $y = 0.0624x + 13334.43$ $n = 14$; $R^2 = 0.08$
 1978-1982 $y = 0.4703x - 20948.67$ $n = 5$; $R^2 = 0.81$ Significant at $P < 0.05*$

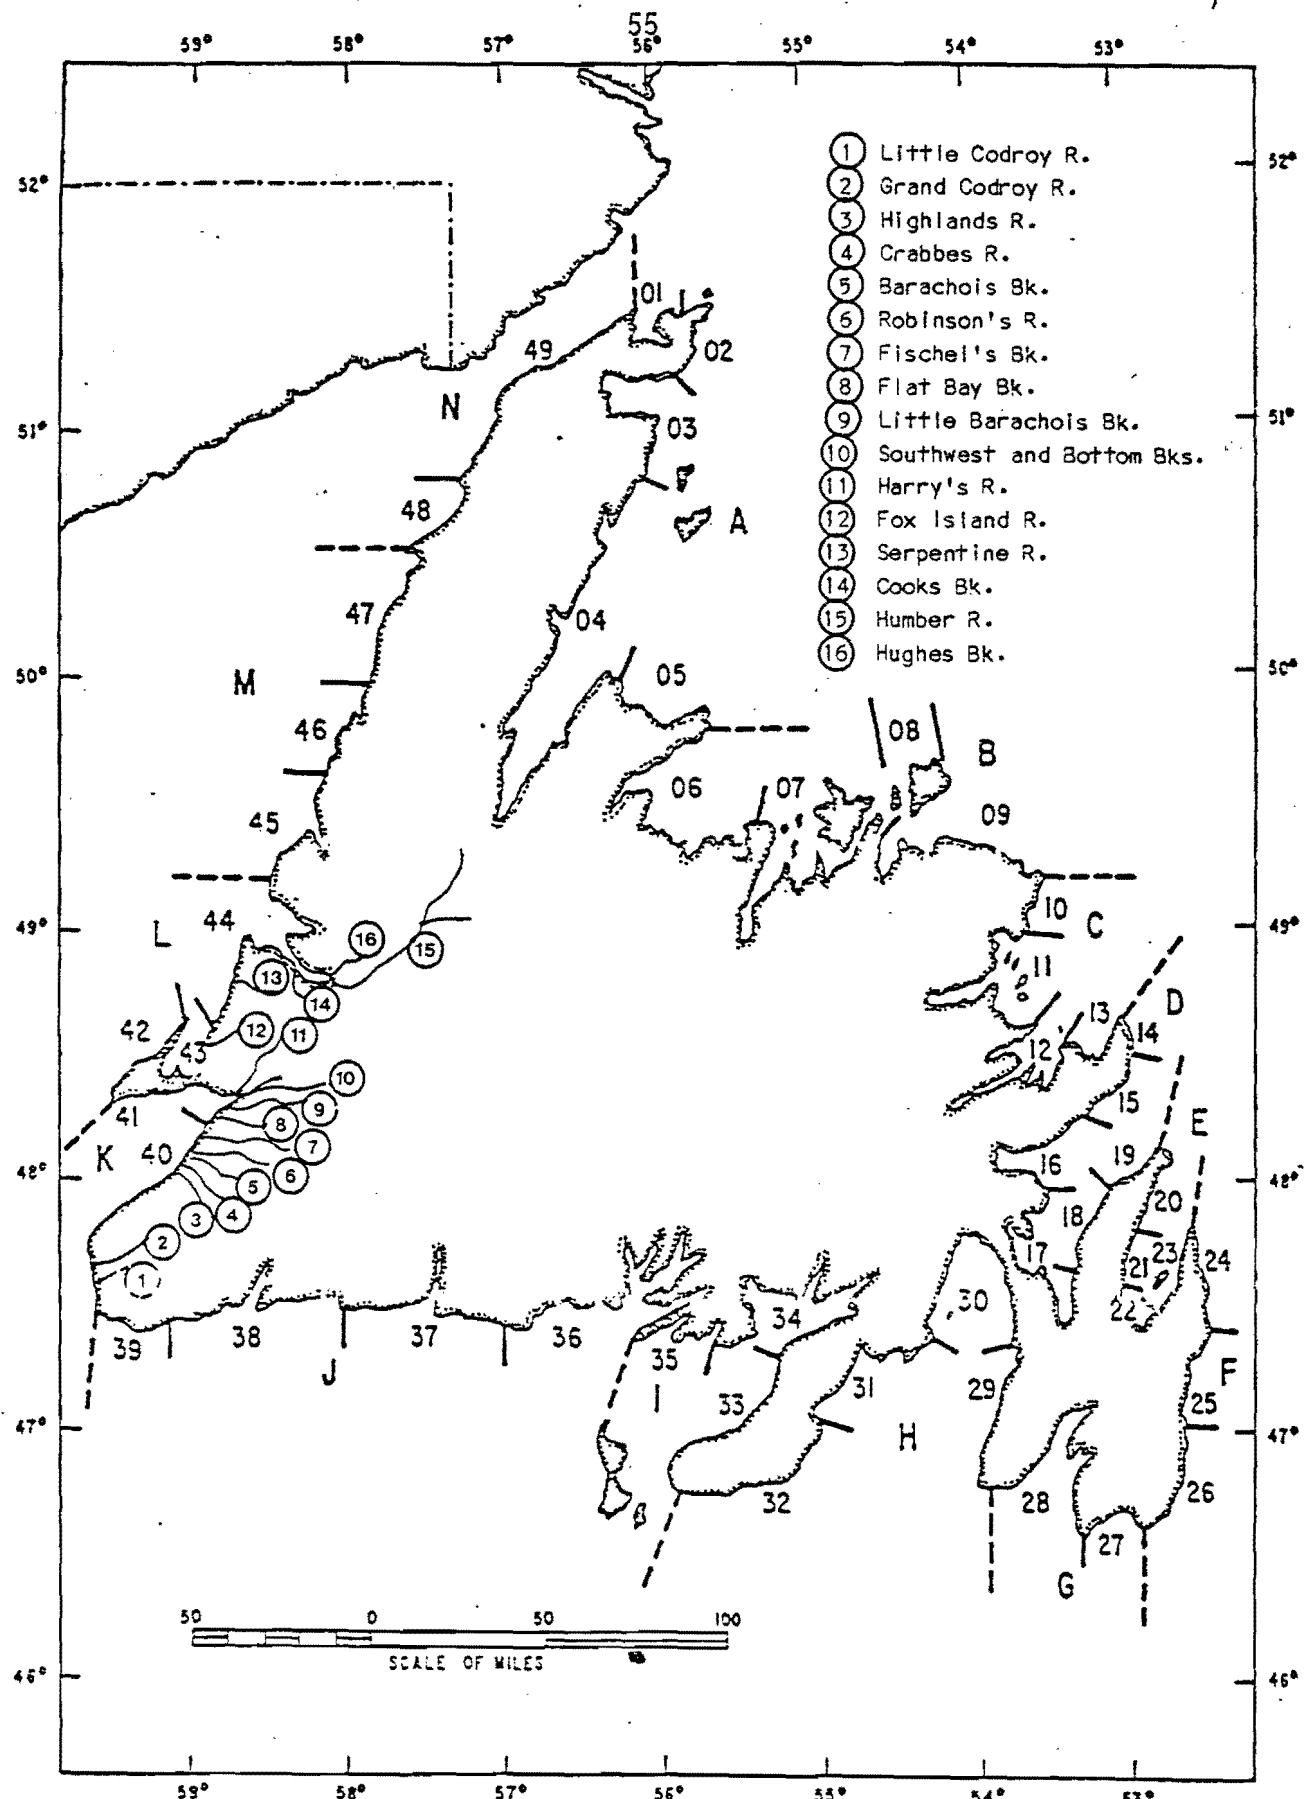

Fig. 1. Boundaries of Statistical Section (numerically indicated) and Statistical Areas (alphabetical) in insular Newfoundland. Major river systems in Areas K and L are also shown.

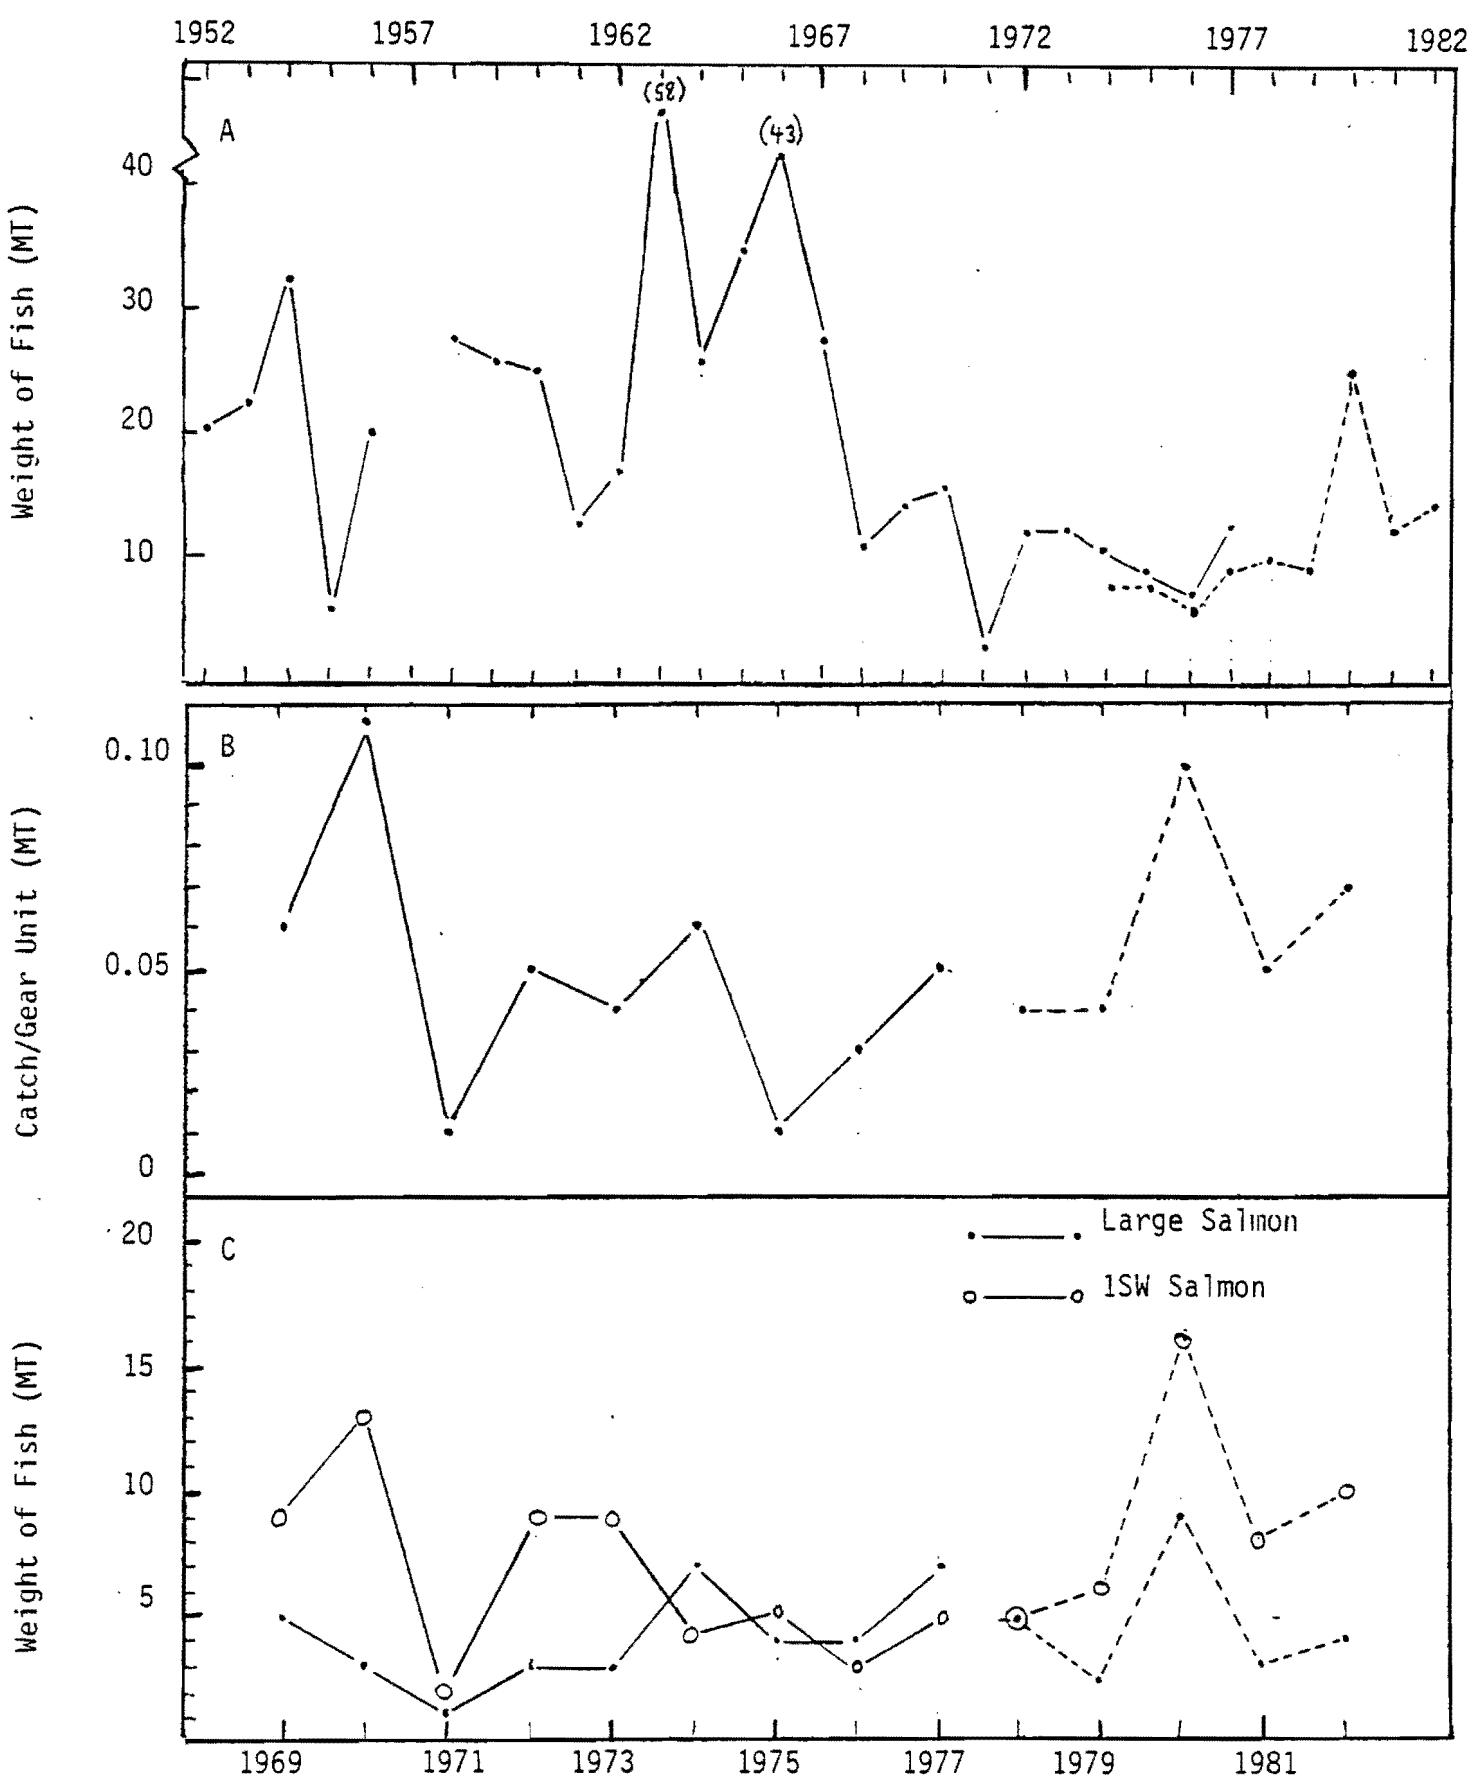

Fig. 2. A - Total weight of salmon (1952-82); B - catch per gear unit (1 unit = 50 fathoms) (1969-82); C - weight of large salmon and 1SW salmon (1969-82) harvested by commercial fishery in Area L. Solid line represents season May 15-Dec. 31. Broken line represents season June 1-July 10.

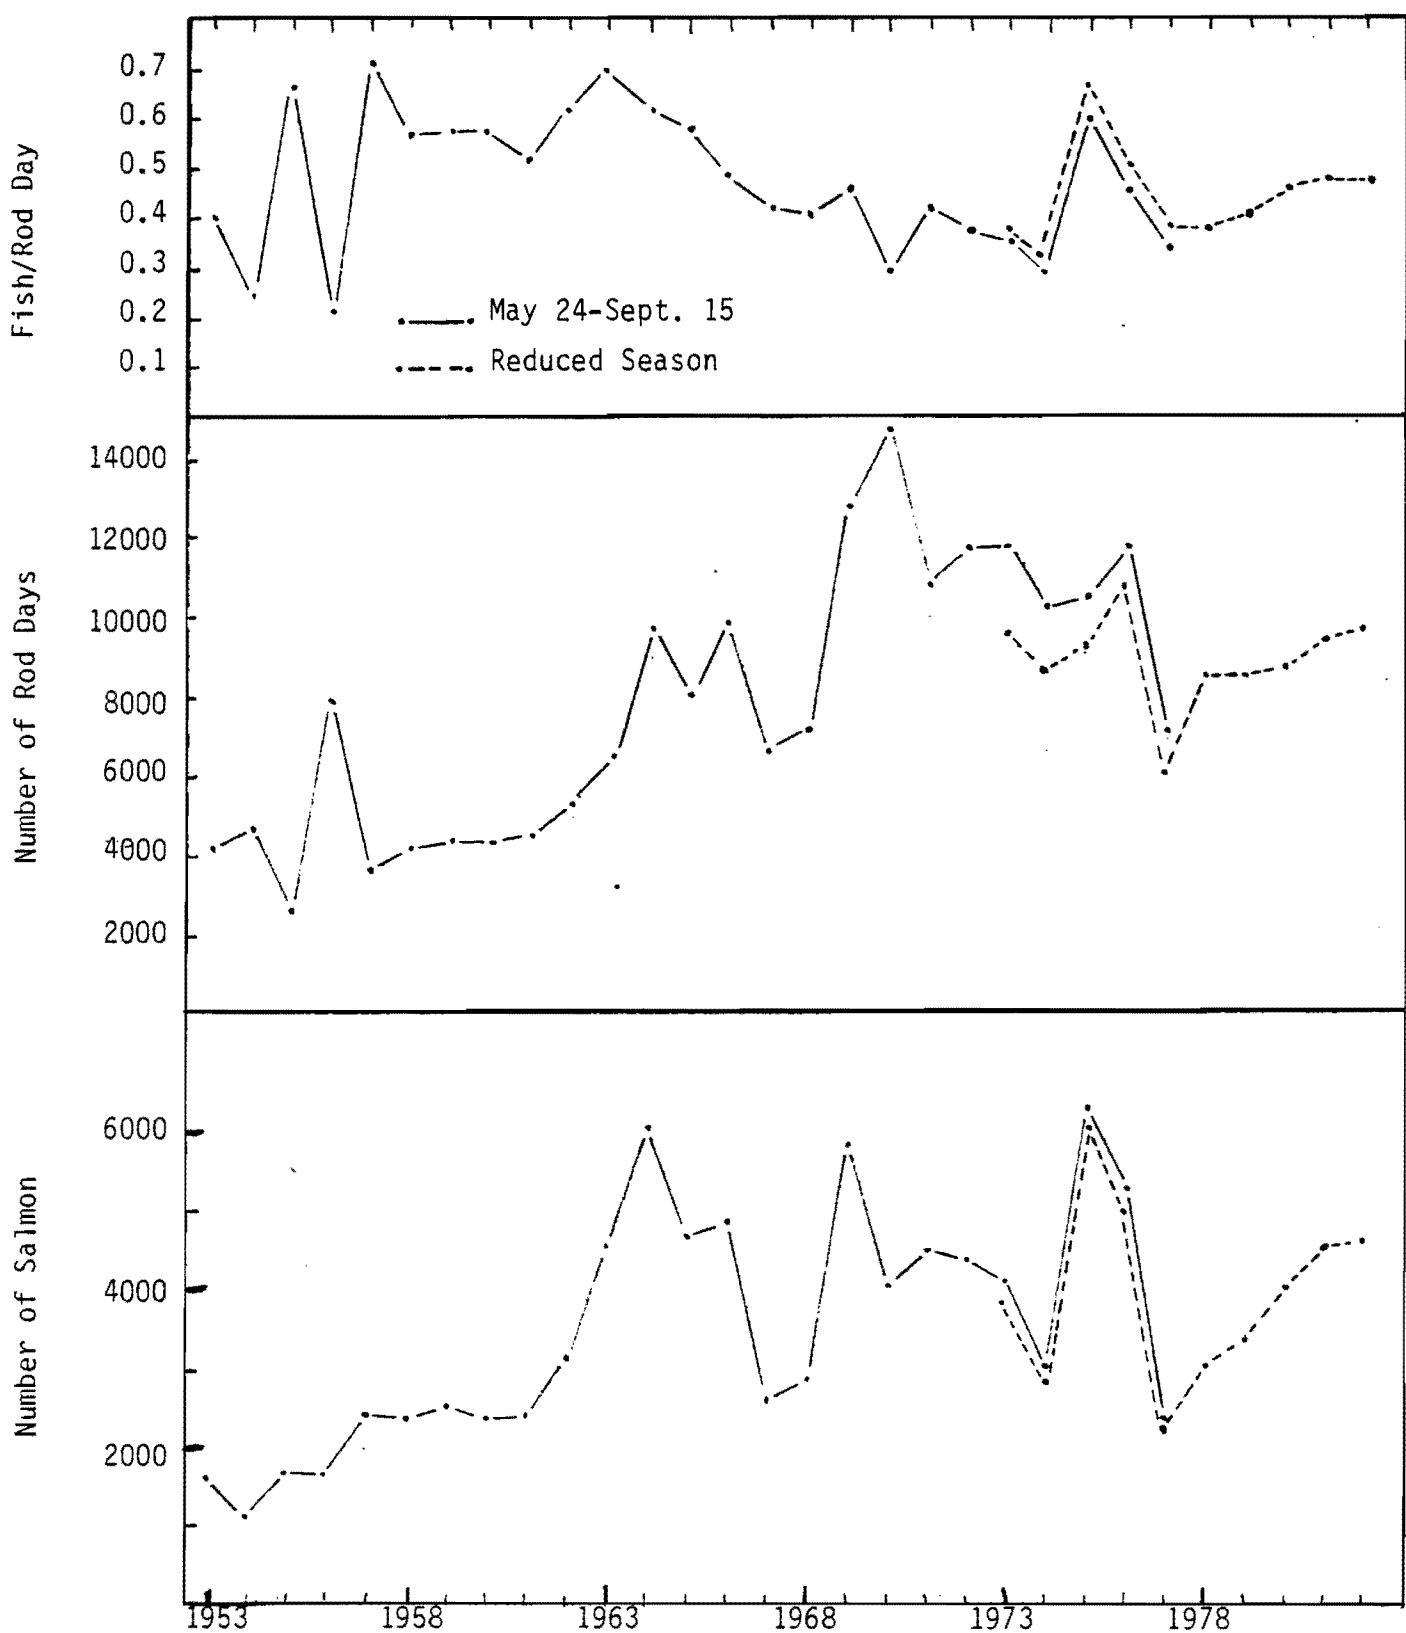

Fig. 3. Total Atlantic salmon angling catch statistics in Area L, May 24-Sept. 15, 1953-1977; and during the reduced season 1973-82.

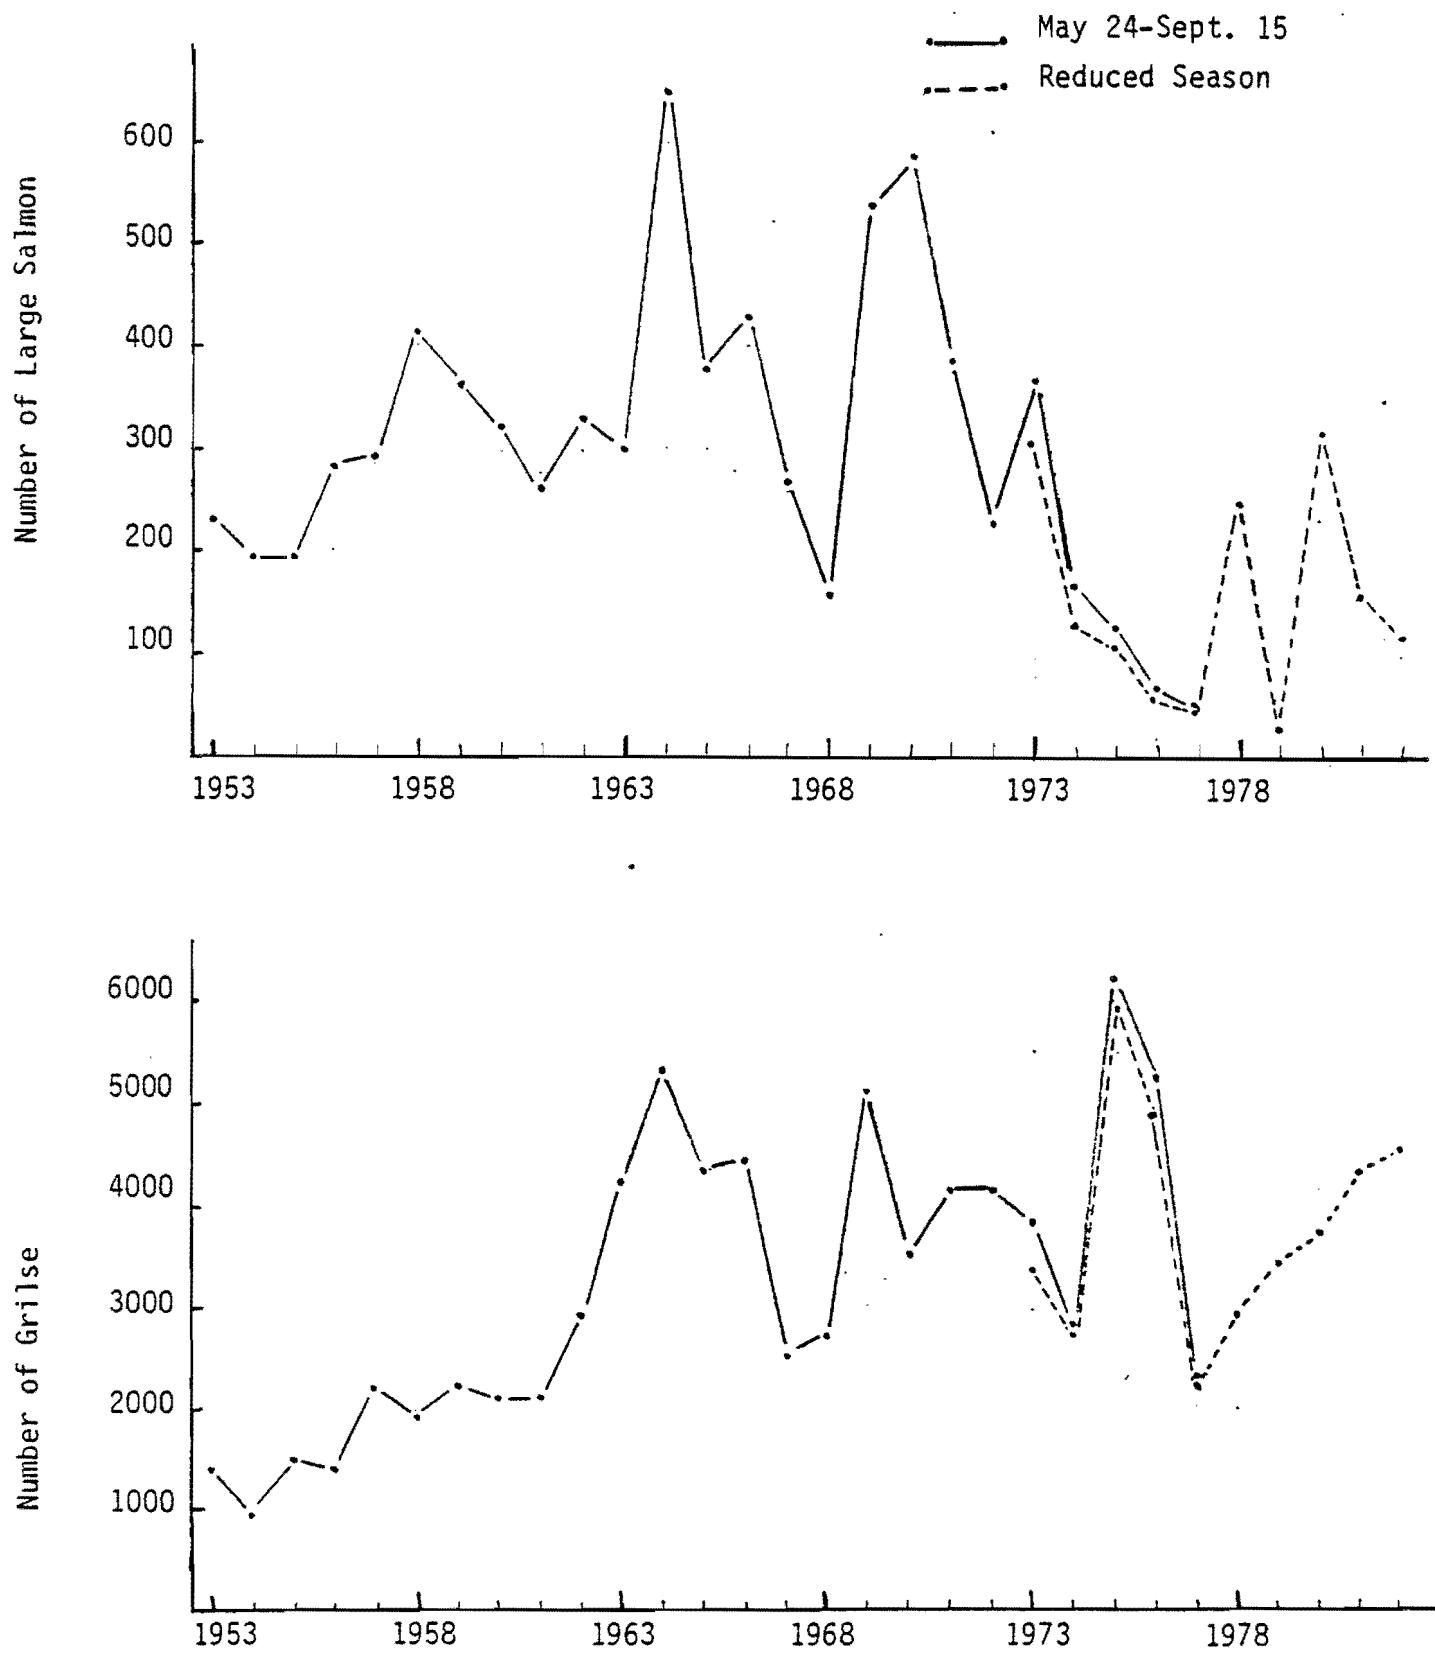

Fig. 4. Numbers of large salmon and grilse angled in Area L, May 24-Sept. 15, 1953-1977; and during the reduced season 1973-82.

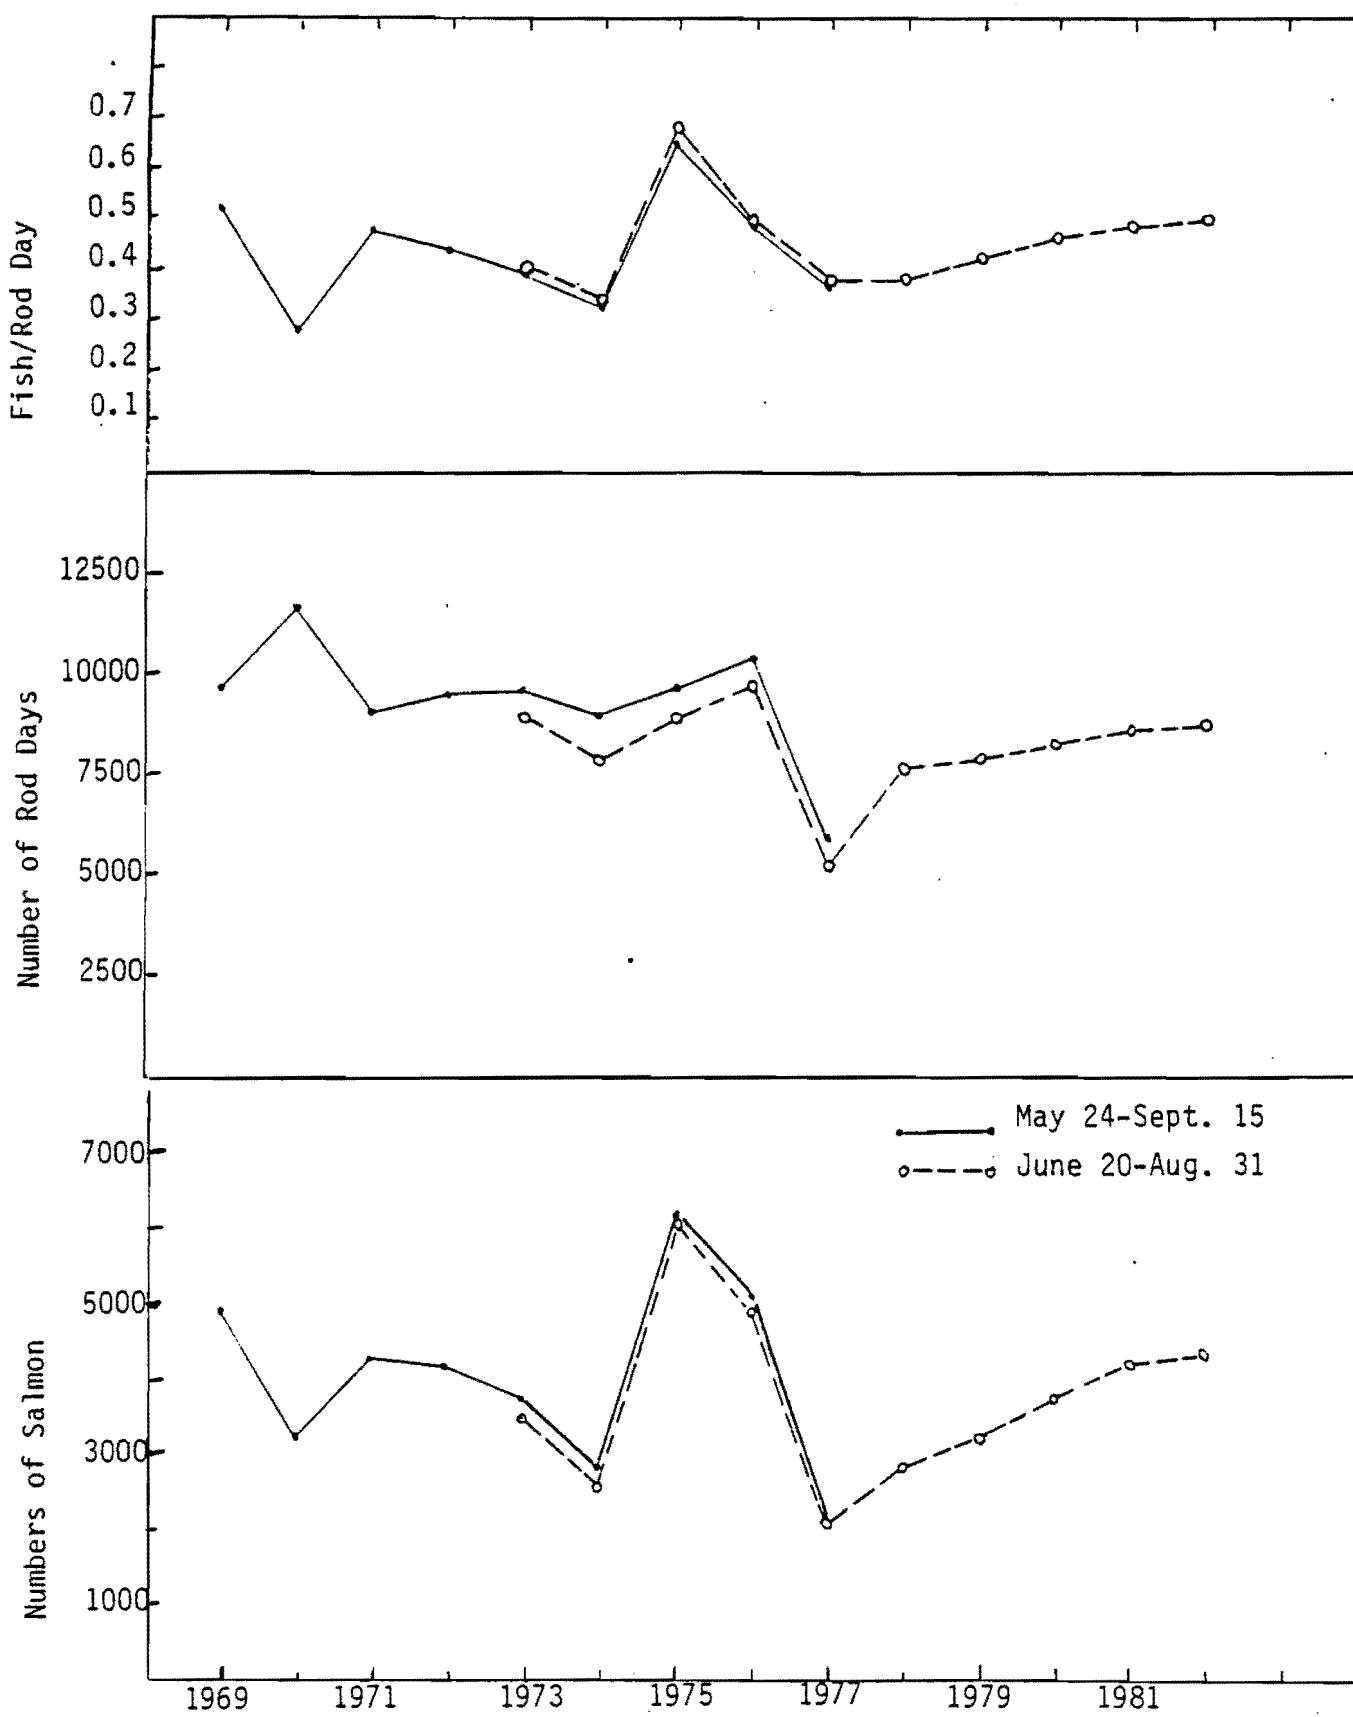

Fig. 5. Total Atlantic salmon angling catch statistics for Humber River May 24-Sept. 15 (1969-1977) and June 20-Aug. 31 (1973-82).

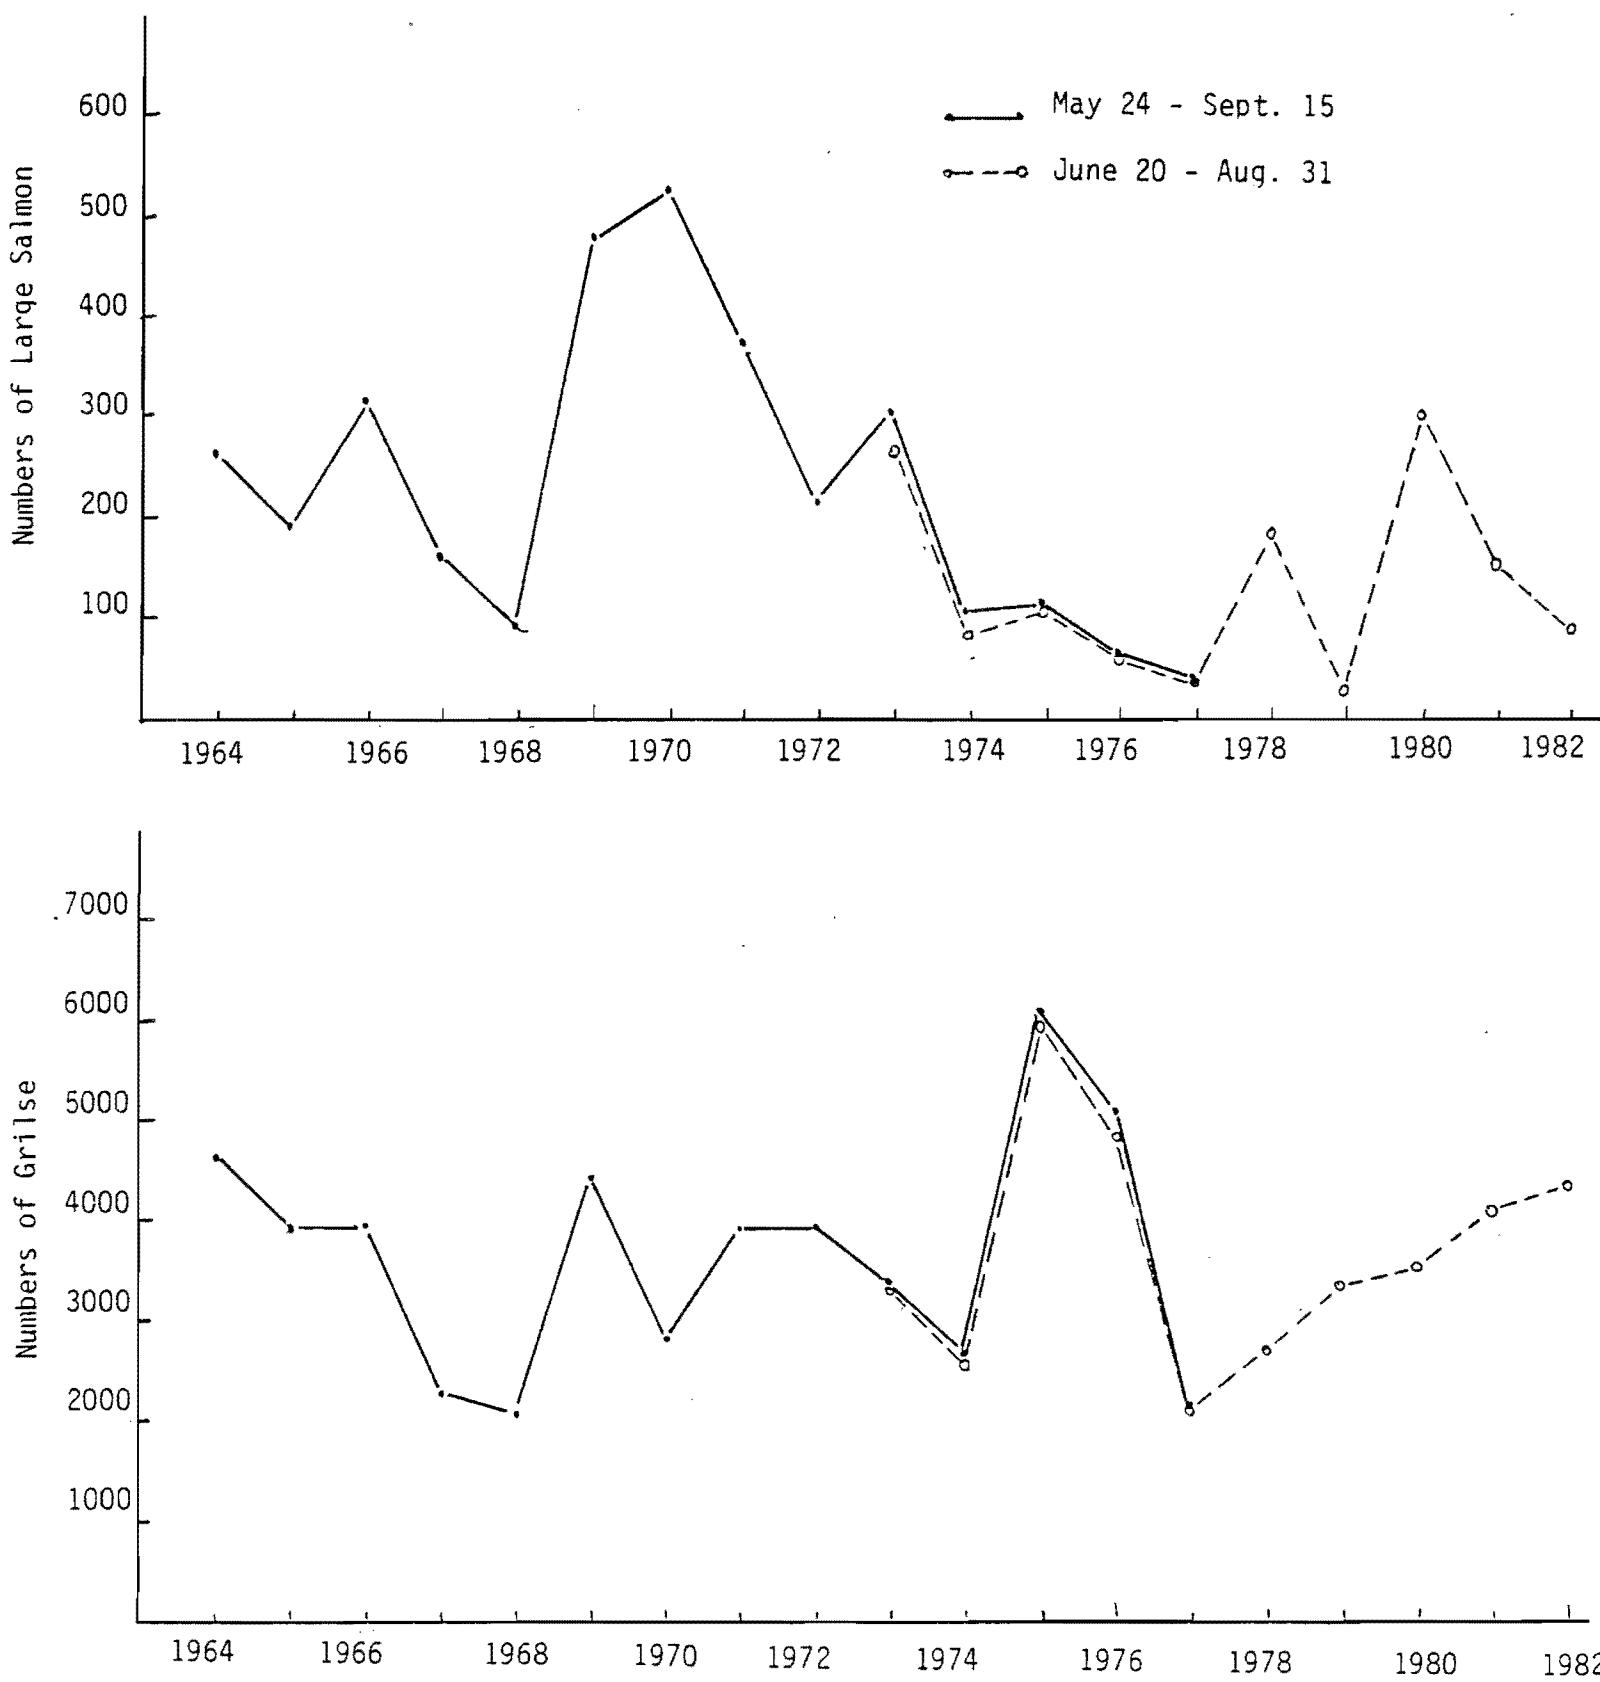

Fig. 6. Numbers of large salmon and grilse angled on Humber River May 24 - Sept. 15 (1964-1977) and June 20 - August 31 (1973-1982).

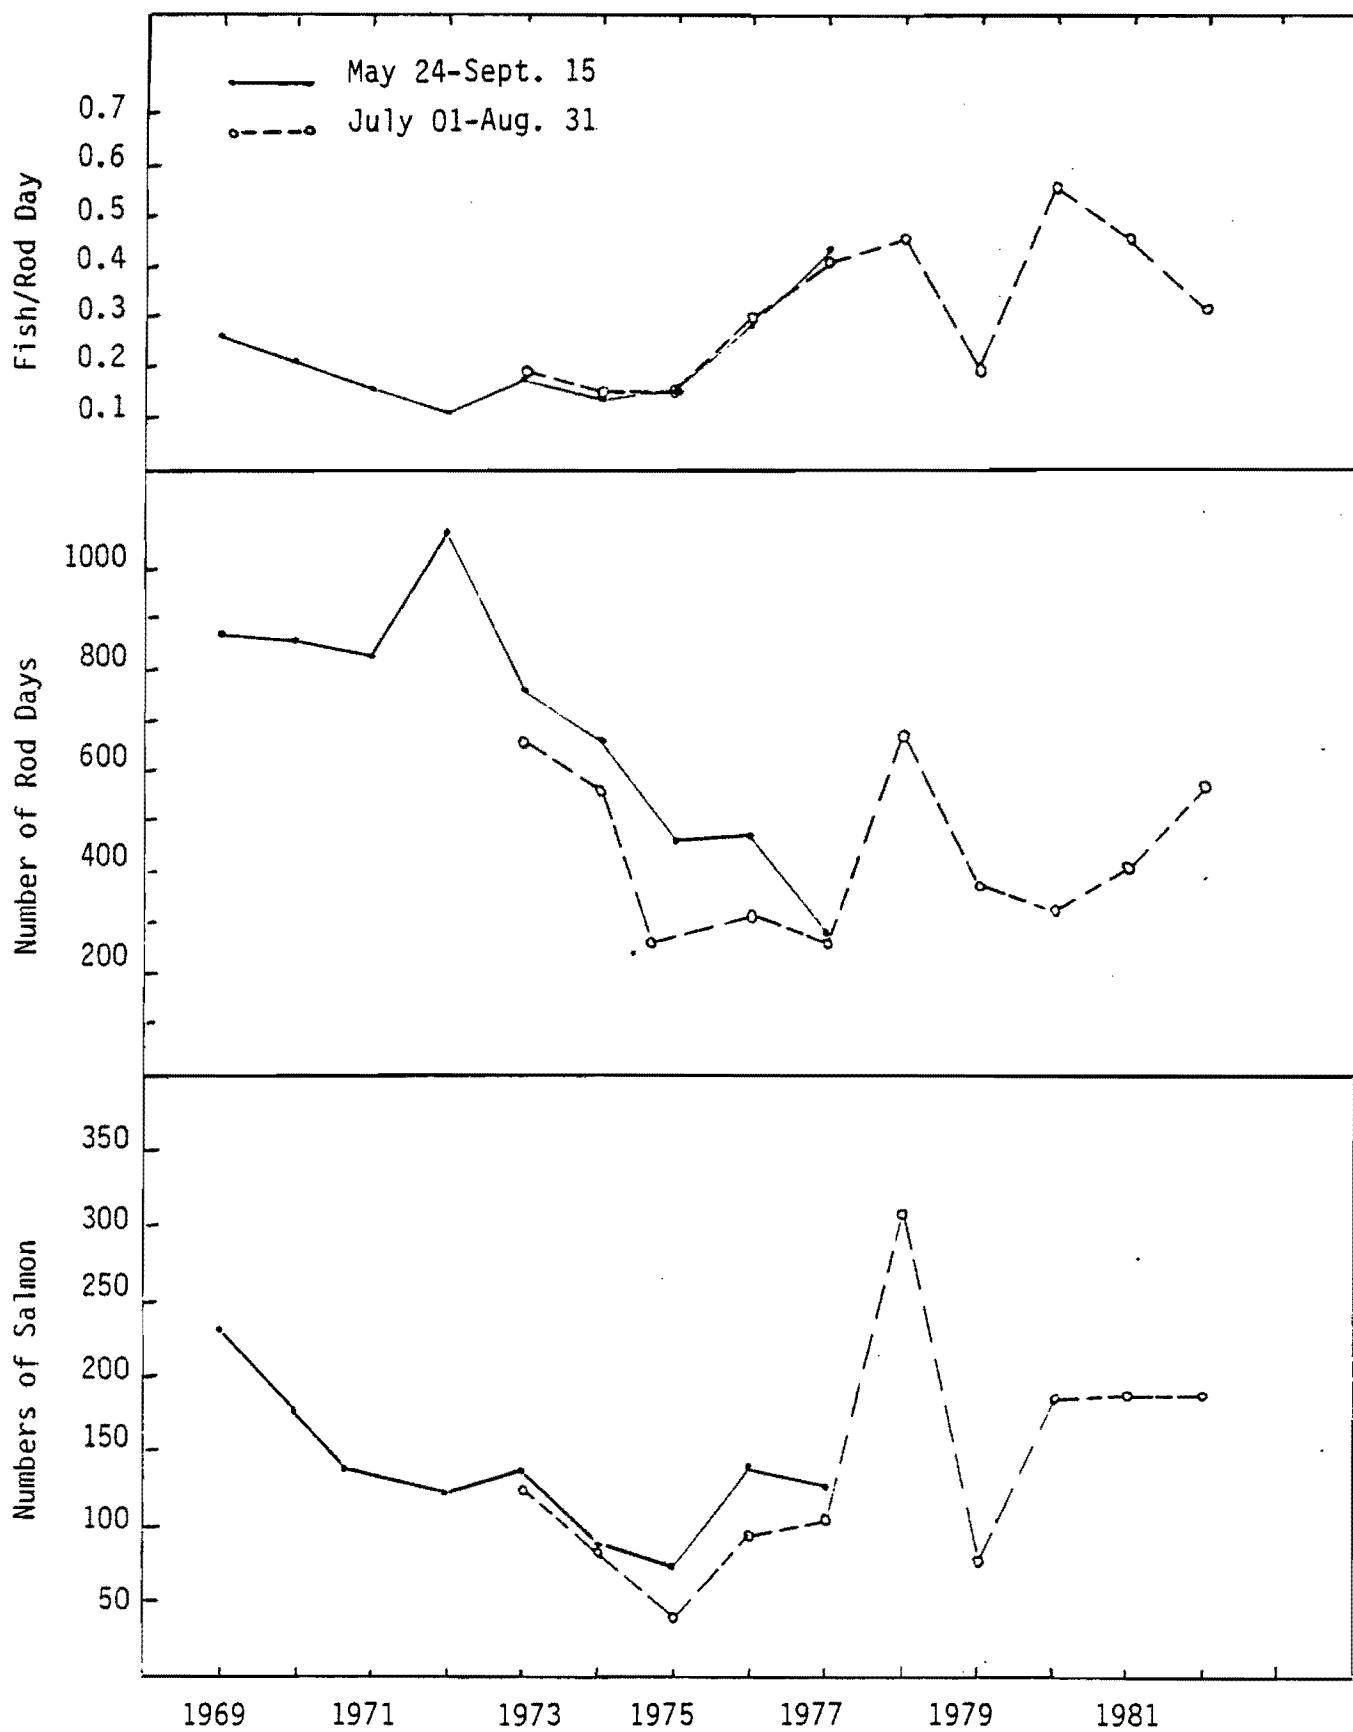

Fig. 7. Total Atlantic salmon angling catch statistics for Serpentine River May 24-Sept. 15 (1969-1982) and July 01-August 31 (1973-1982).

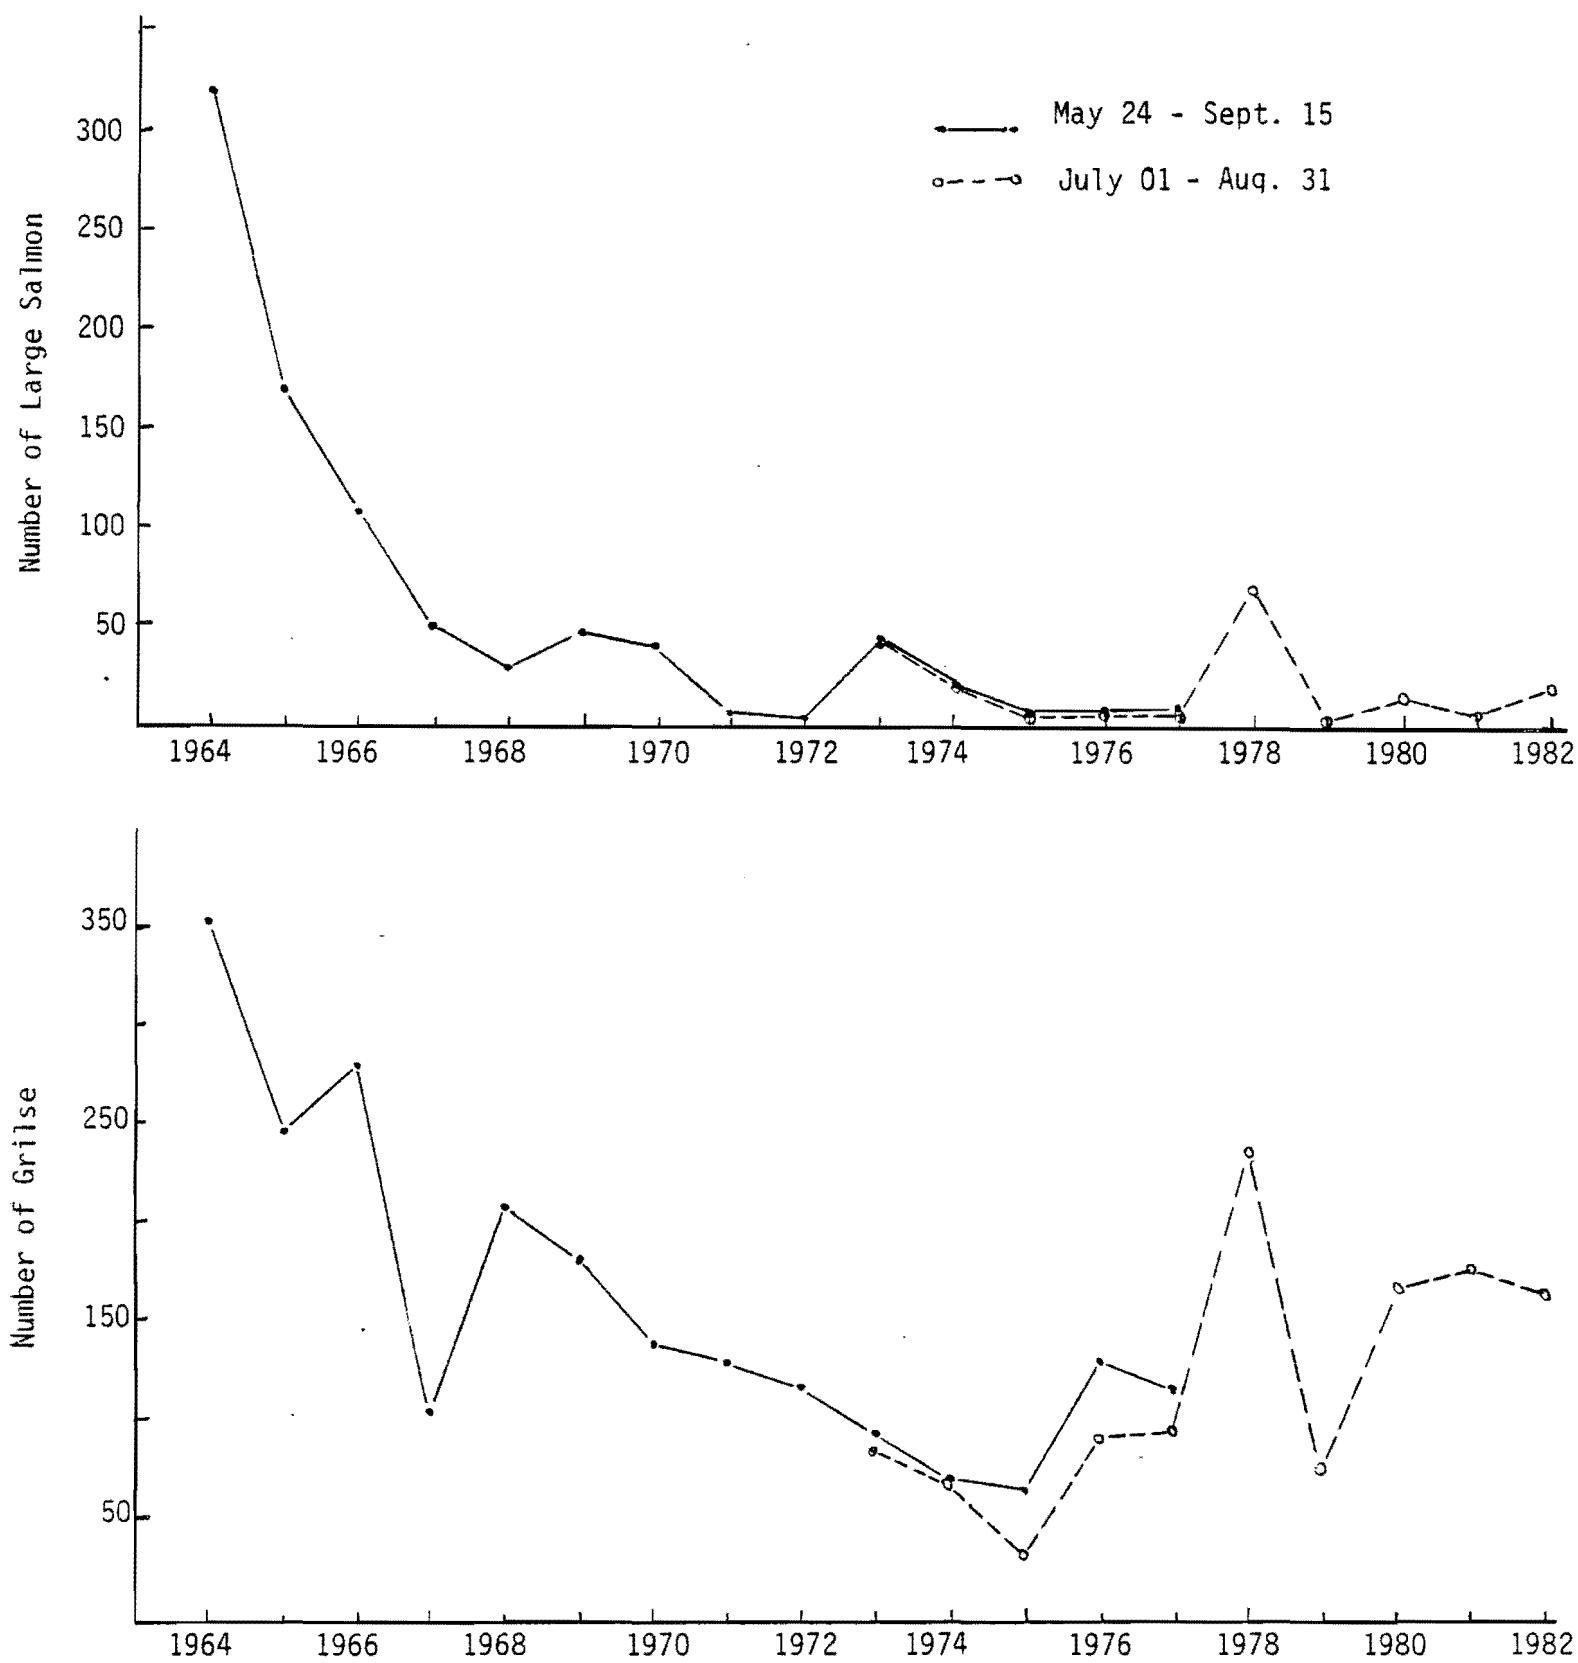

Fig. 8. Numbers of large salmon and grilse angled on Serpentine River May 24 - Sept. 15 (1964-1977) and July 01 - August 31 (1973-1982).

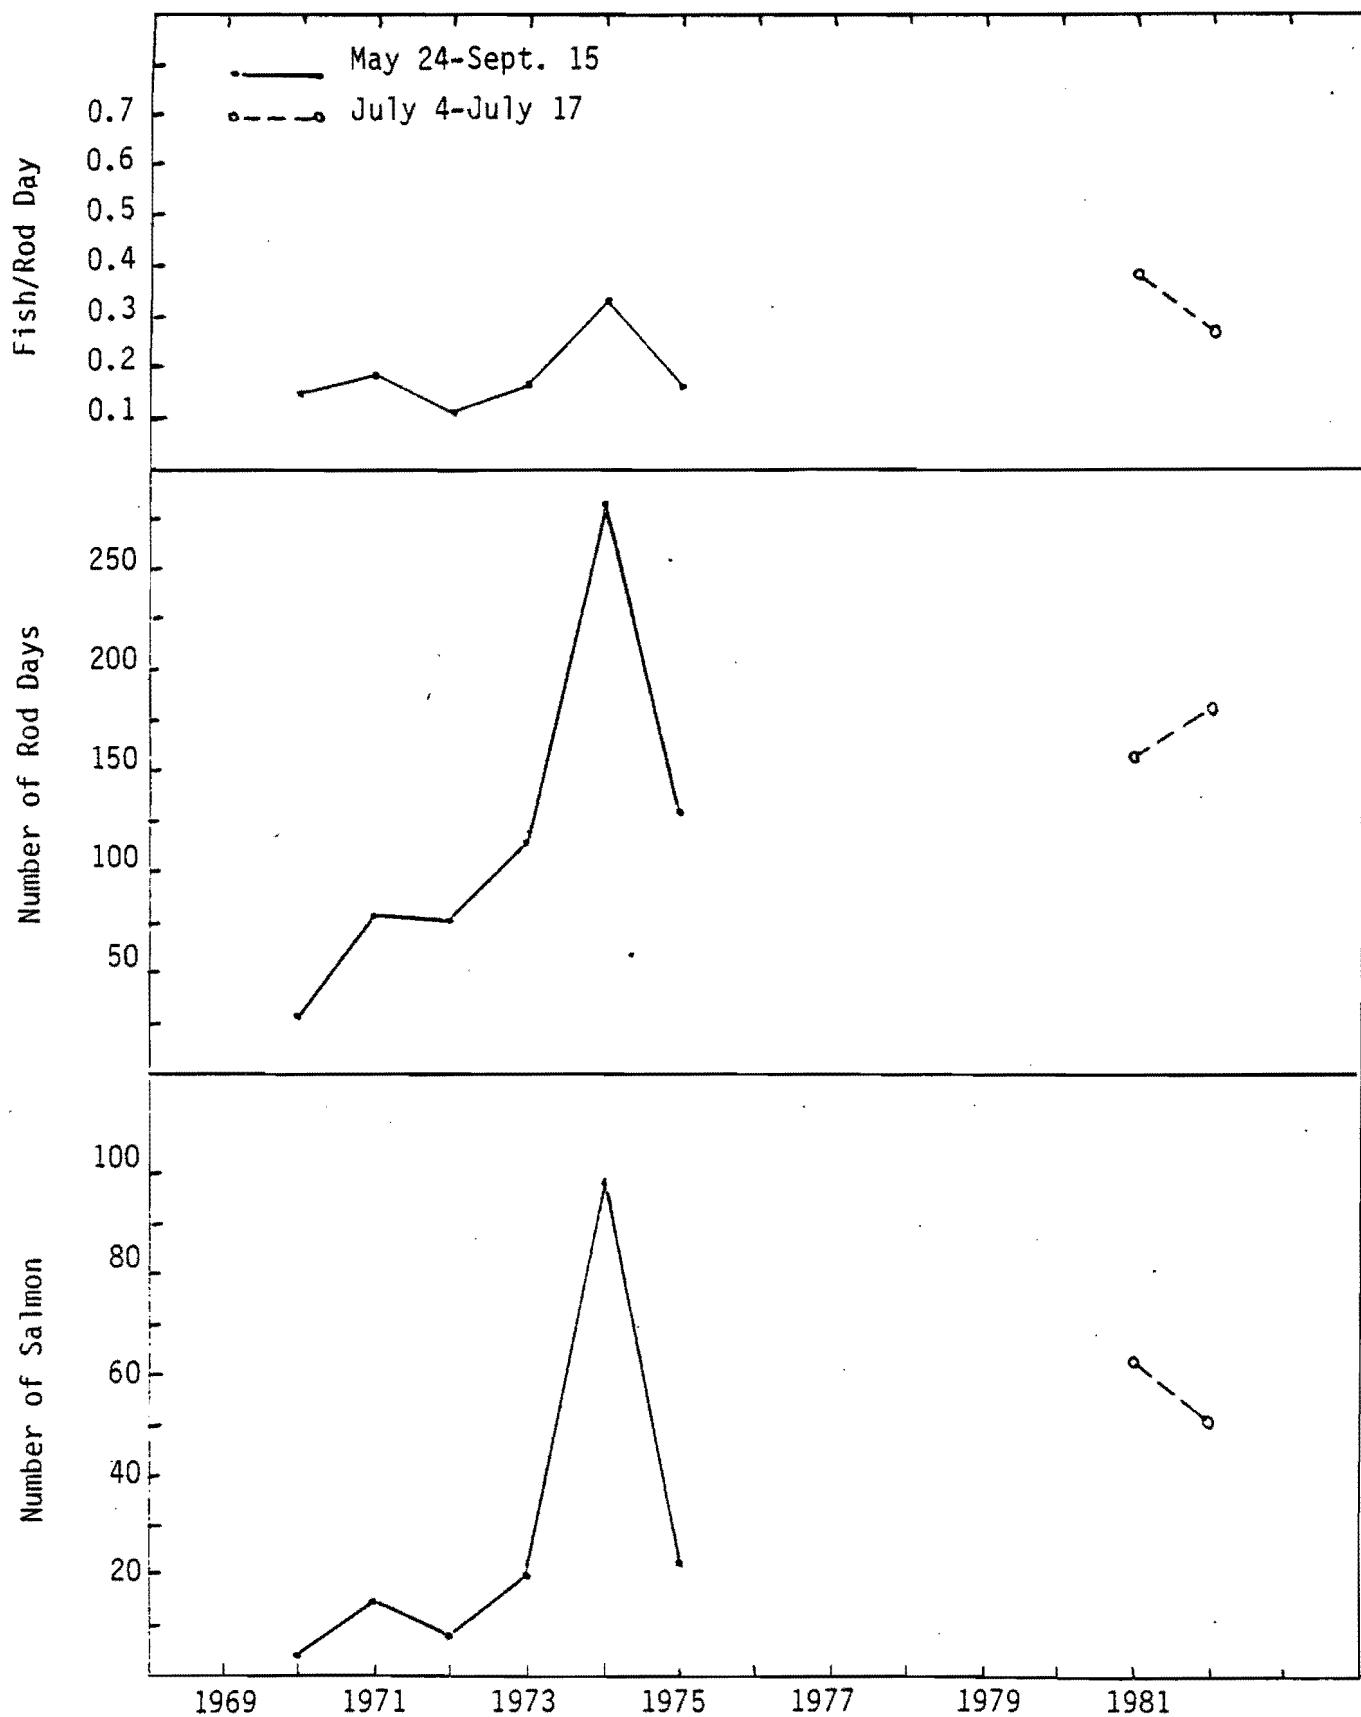

Fig. 9. Total salmon angling catch statistics for Fox Island River May 24-Sept. 15 (1970-1975) and July 4-July 17 (1981-1982).

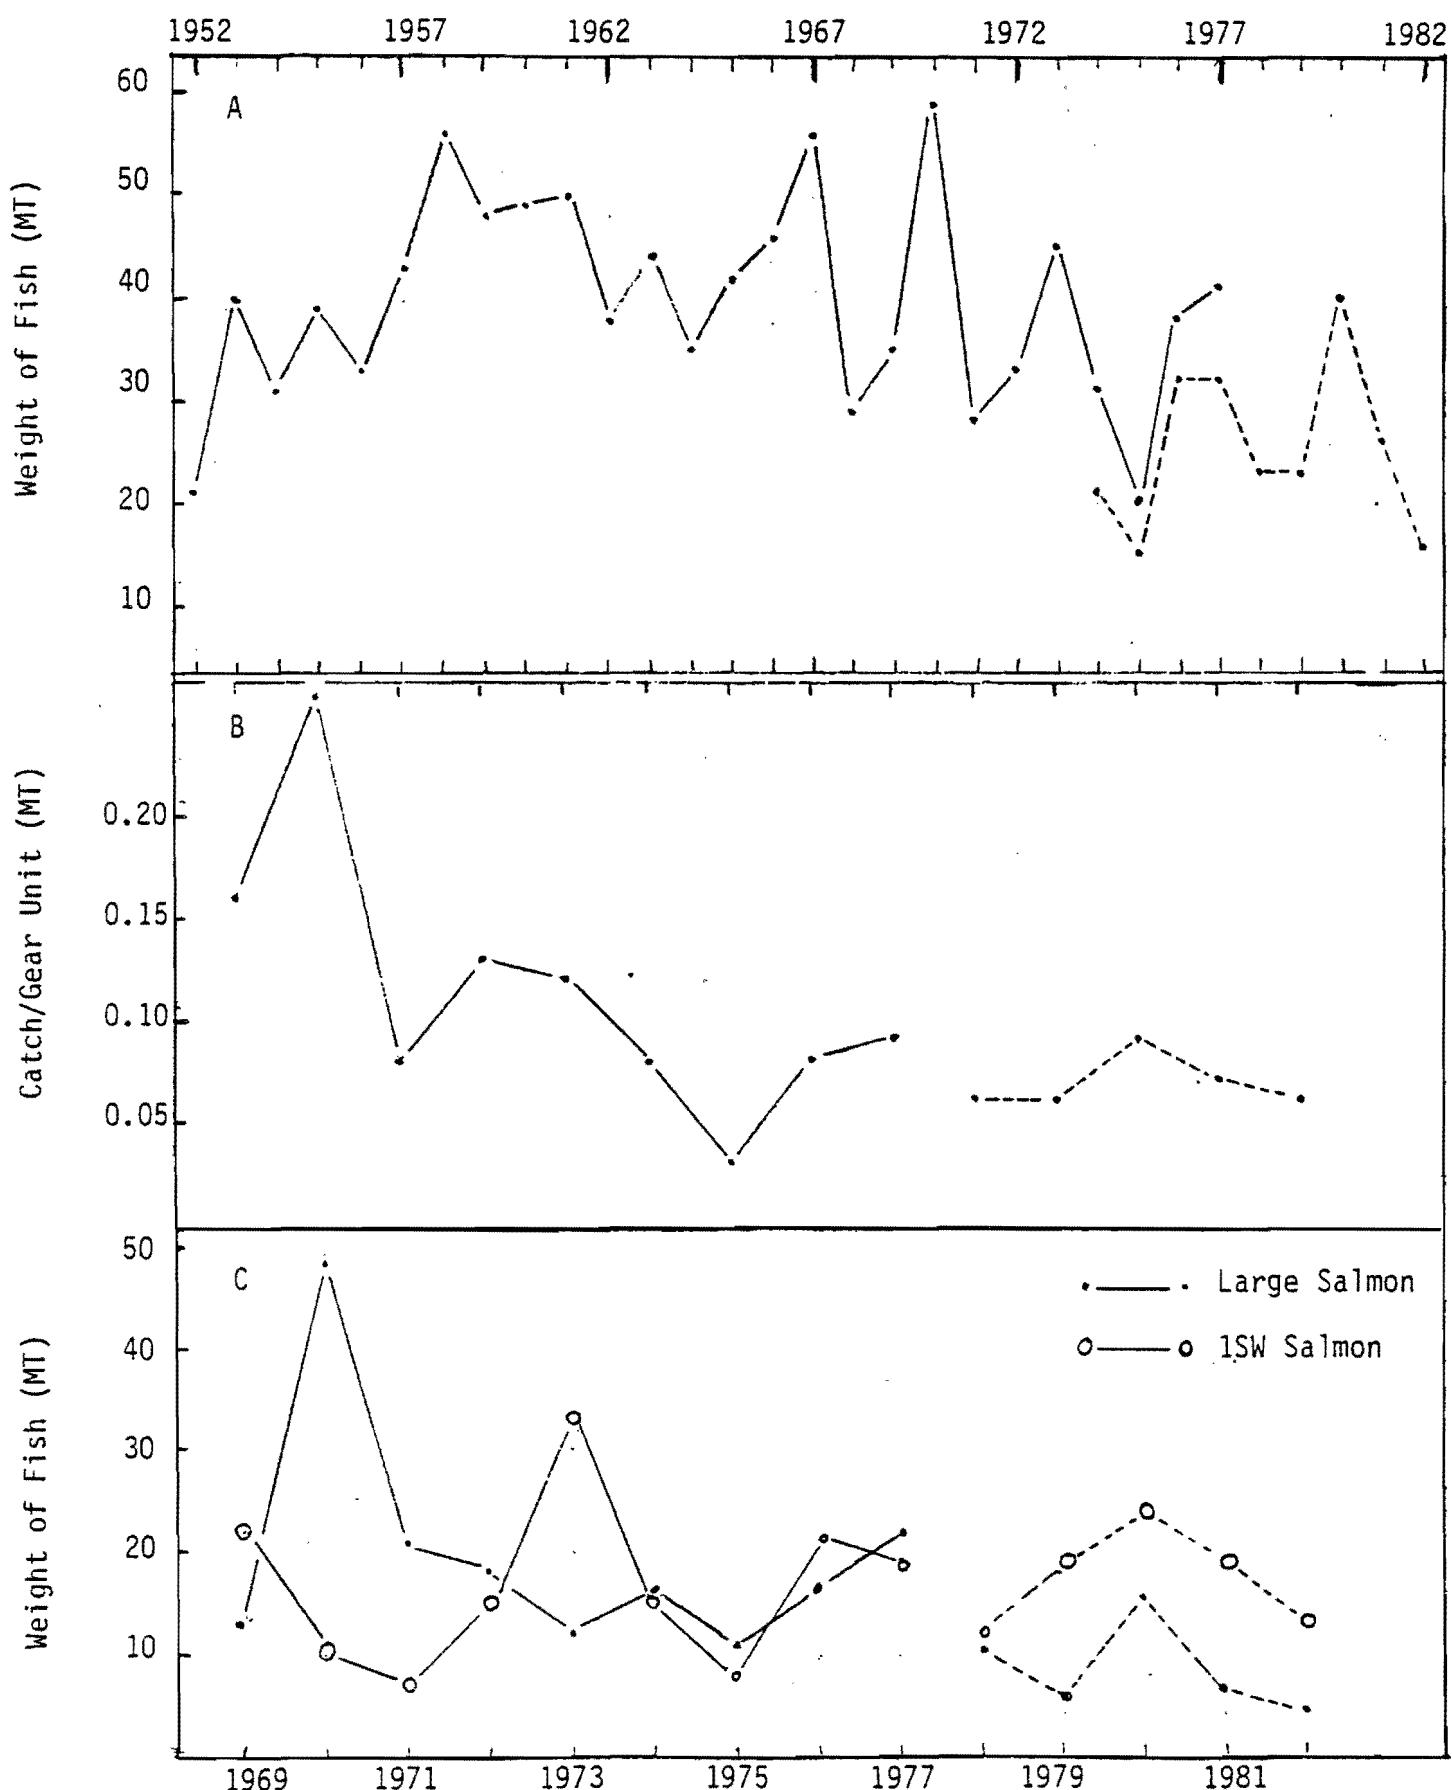

Fig. 10. A - Total weight of salmon (1952-82); B - Catch per gear unit (50 fathoms) 1969-82; and, C - Weight of large salmon and 1SW salmon (1969-82) harvested by commercial fishery in Area K. Solid line represents season May 15-Dec. 31. Broken line represents season June 1-July 10.

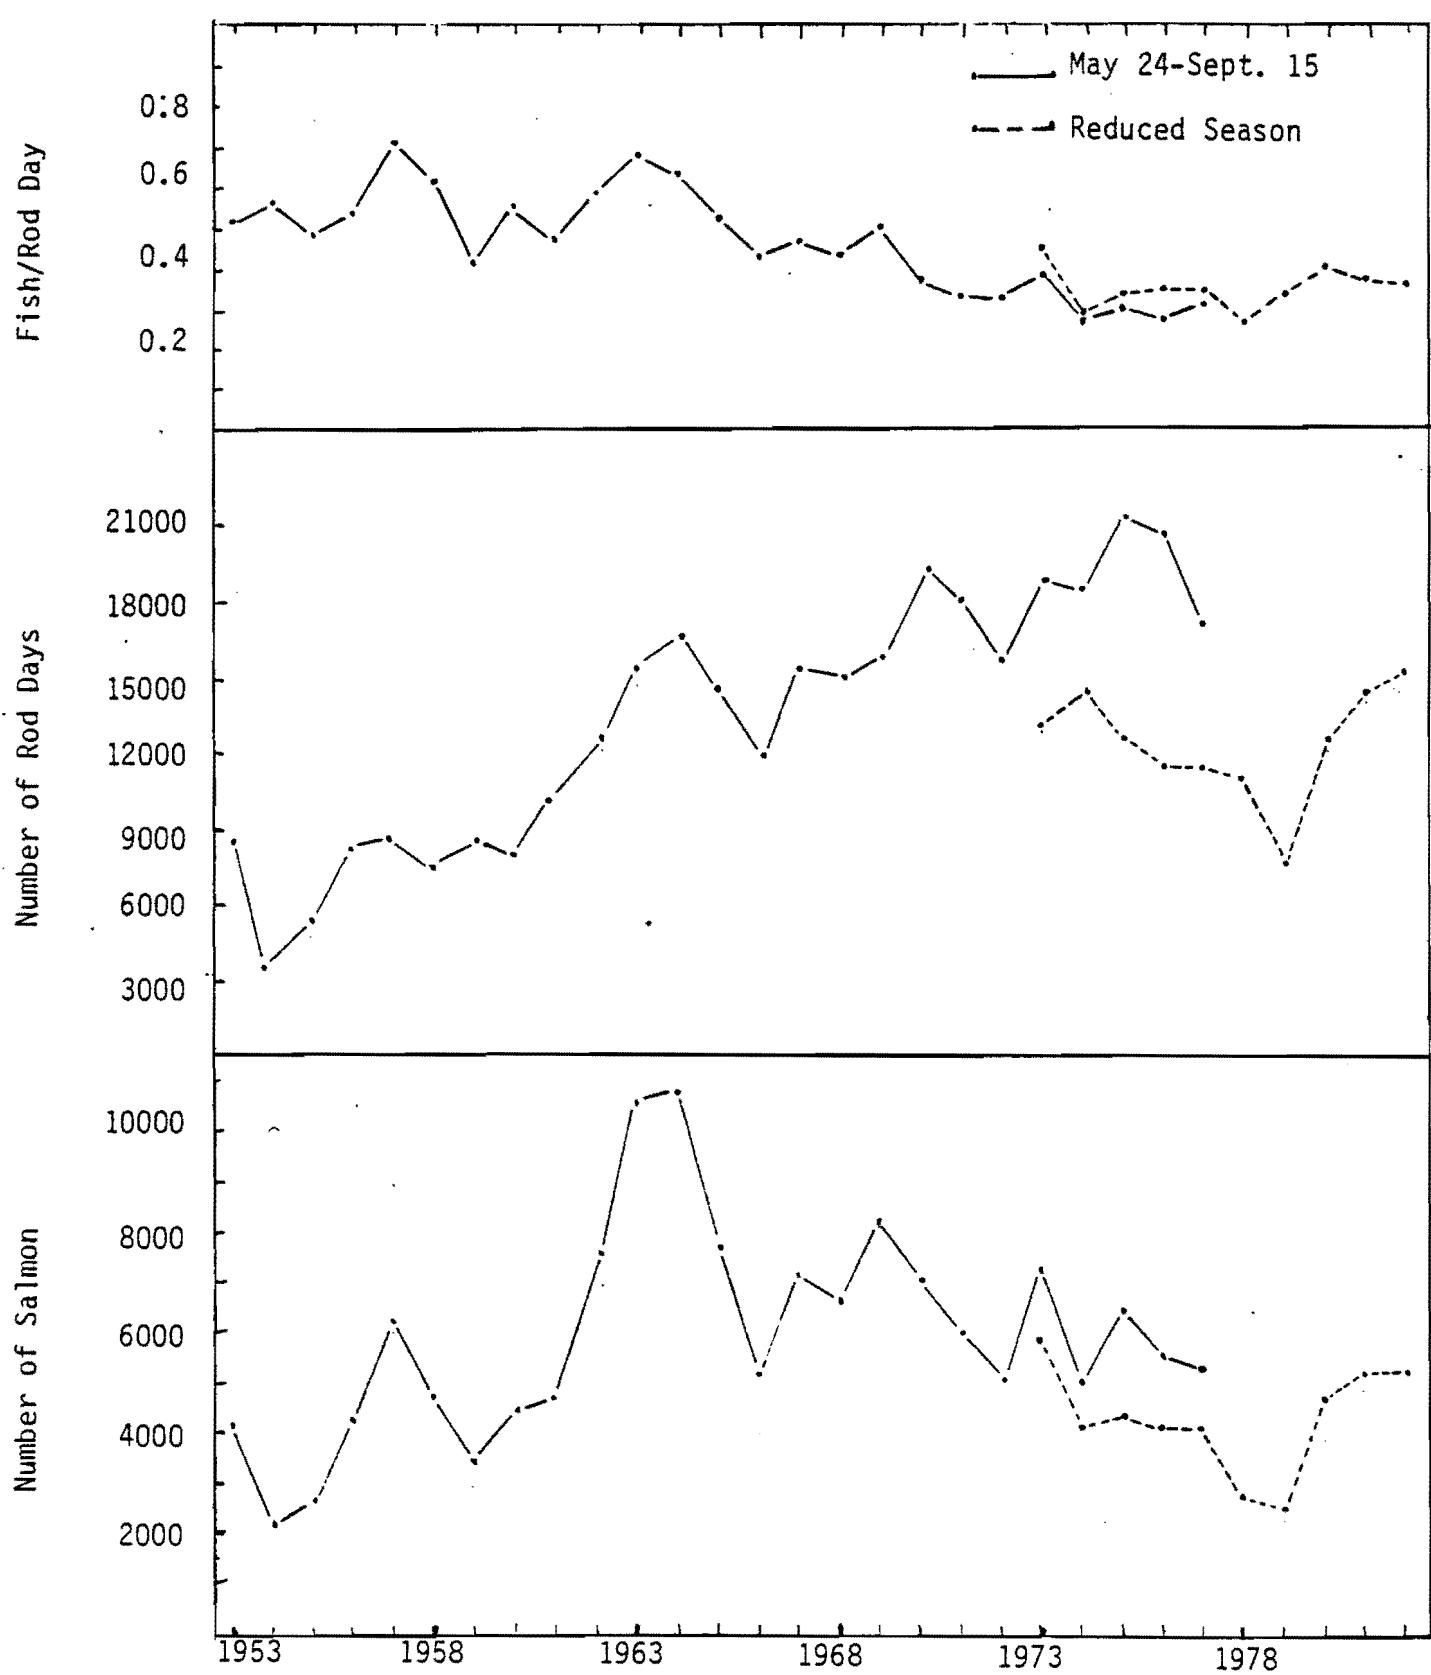

Fig. 11. Total Atlantic salmon angling catch for Area K. May 24-Sept. 15 (1953-1977), and during the reduced angling season 1973-82.

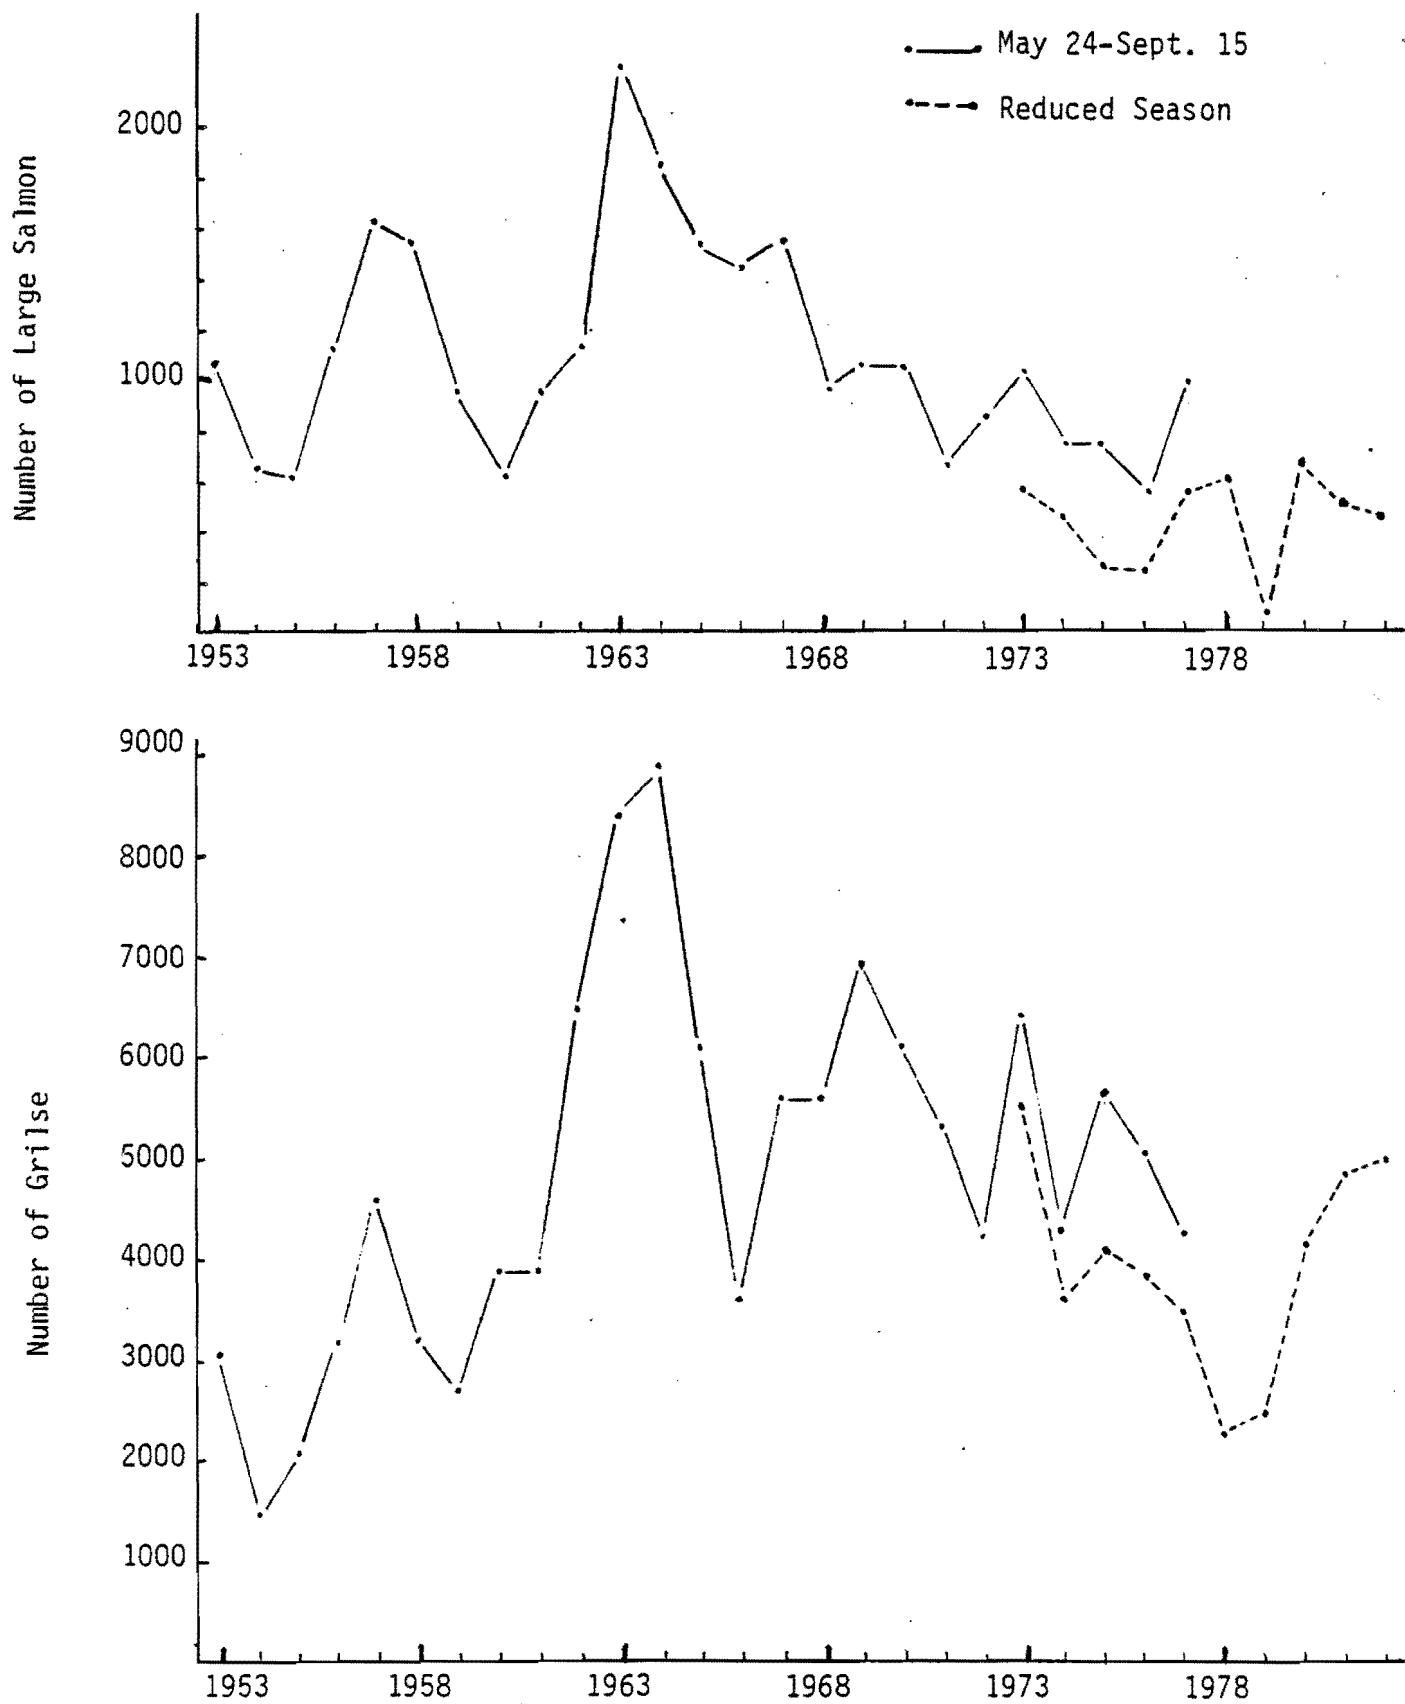

Fig. 12. Numbers of large salmon and grilse angled in Area K, May 24-Sept. 15 1953-1977, and during the reduced season 1973-82.

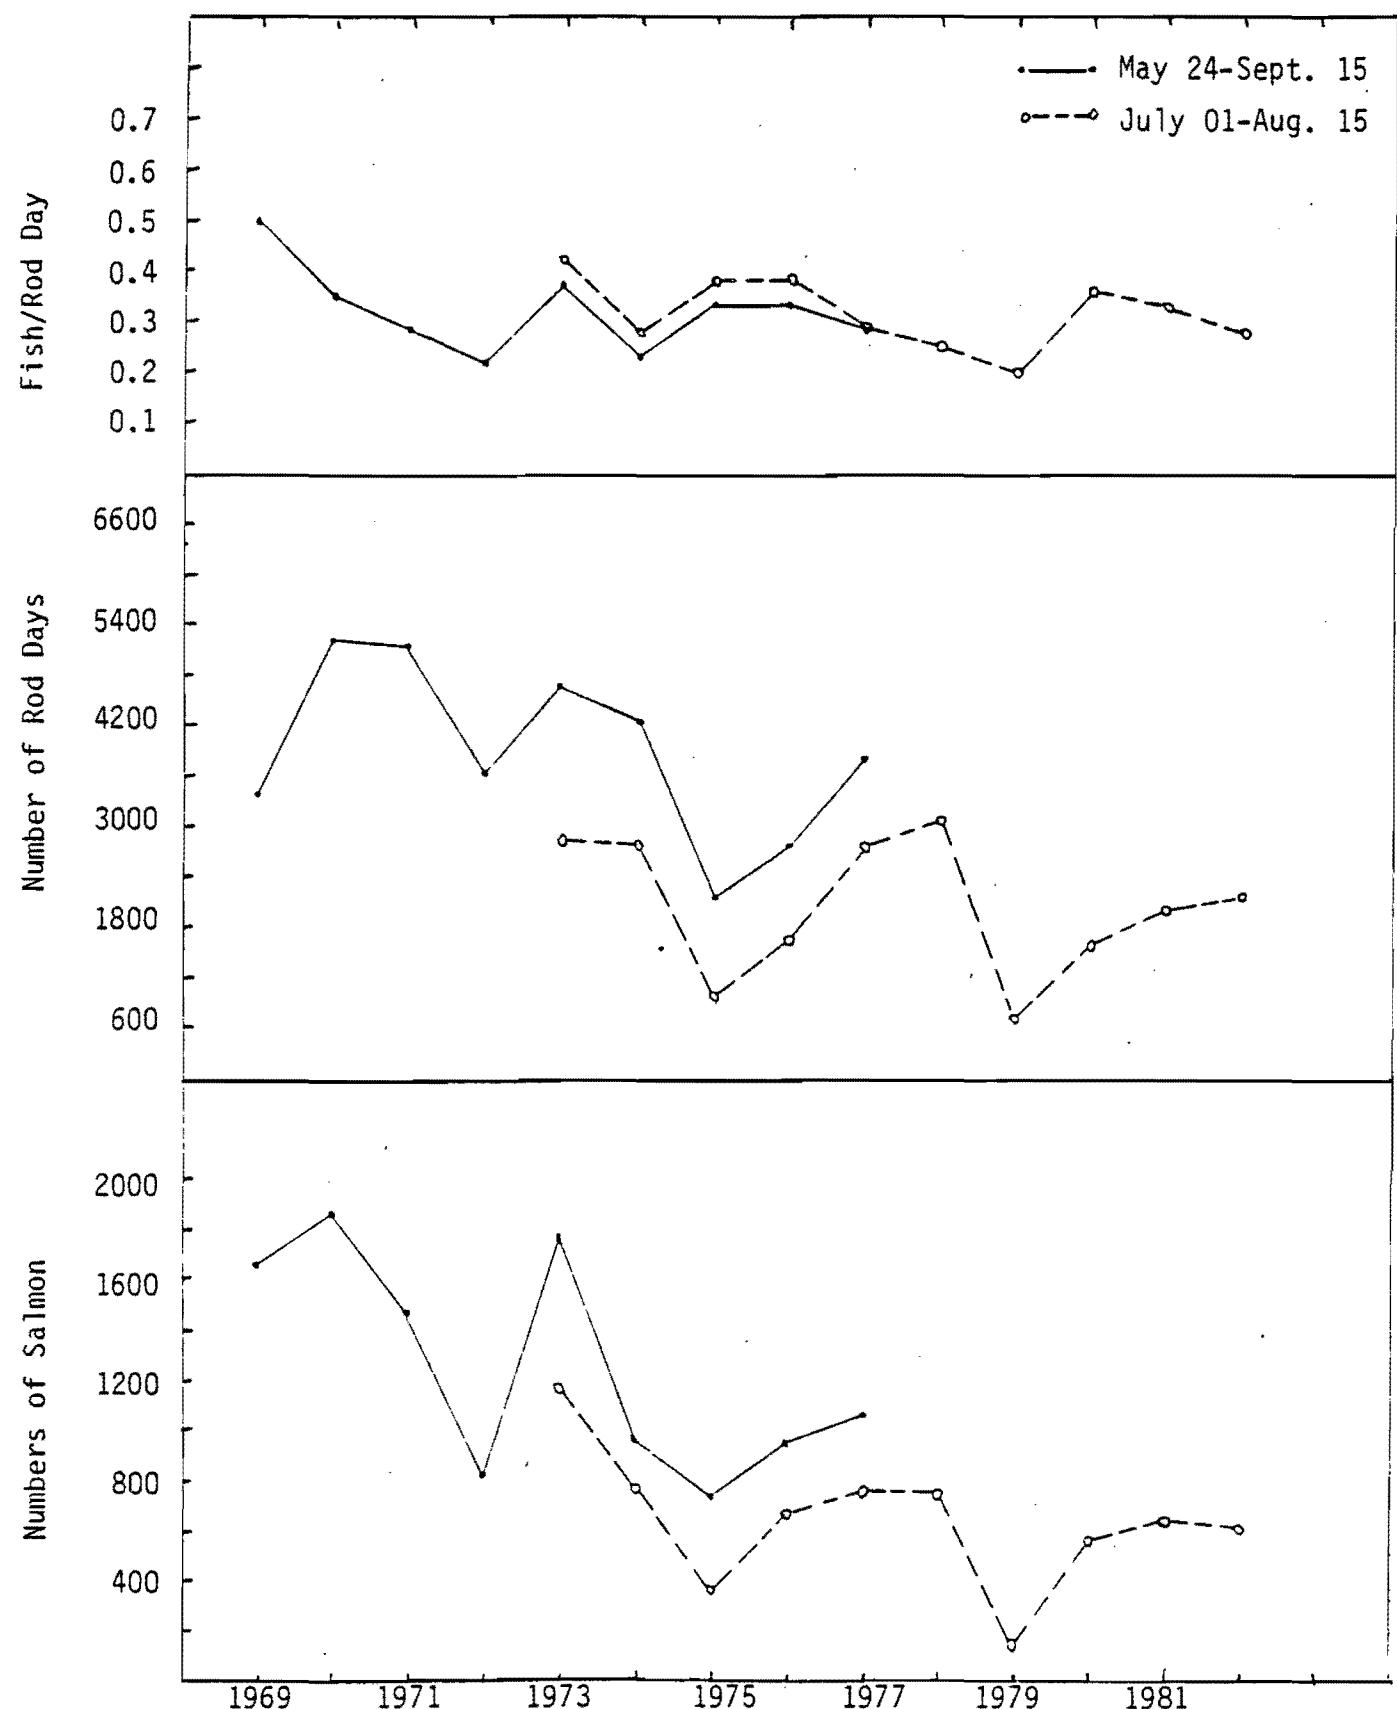

Fig. 13. Total salmon angling catch statistics for Harry's River, May 24-Sept. 15 (1969-1977) and July 01-August 15 (1973-1982).

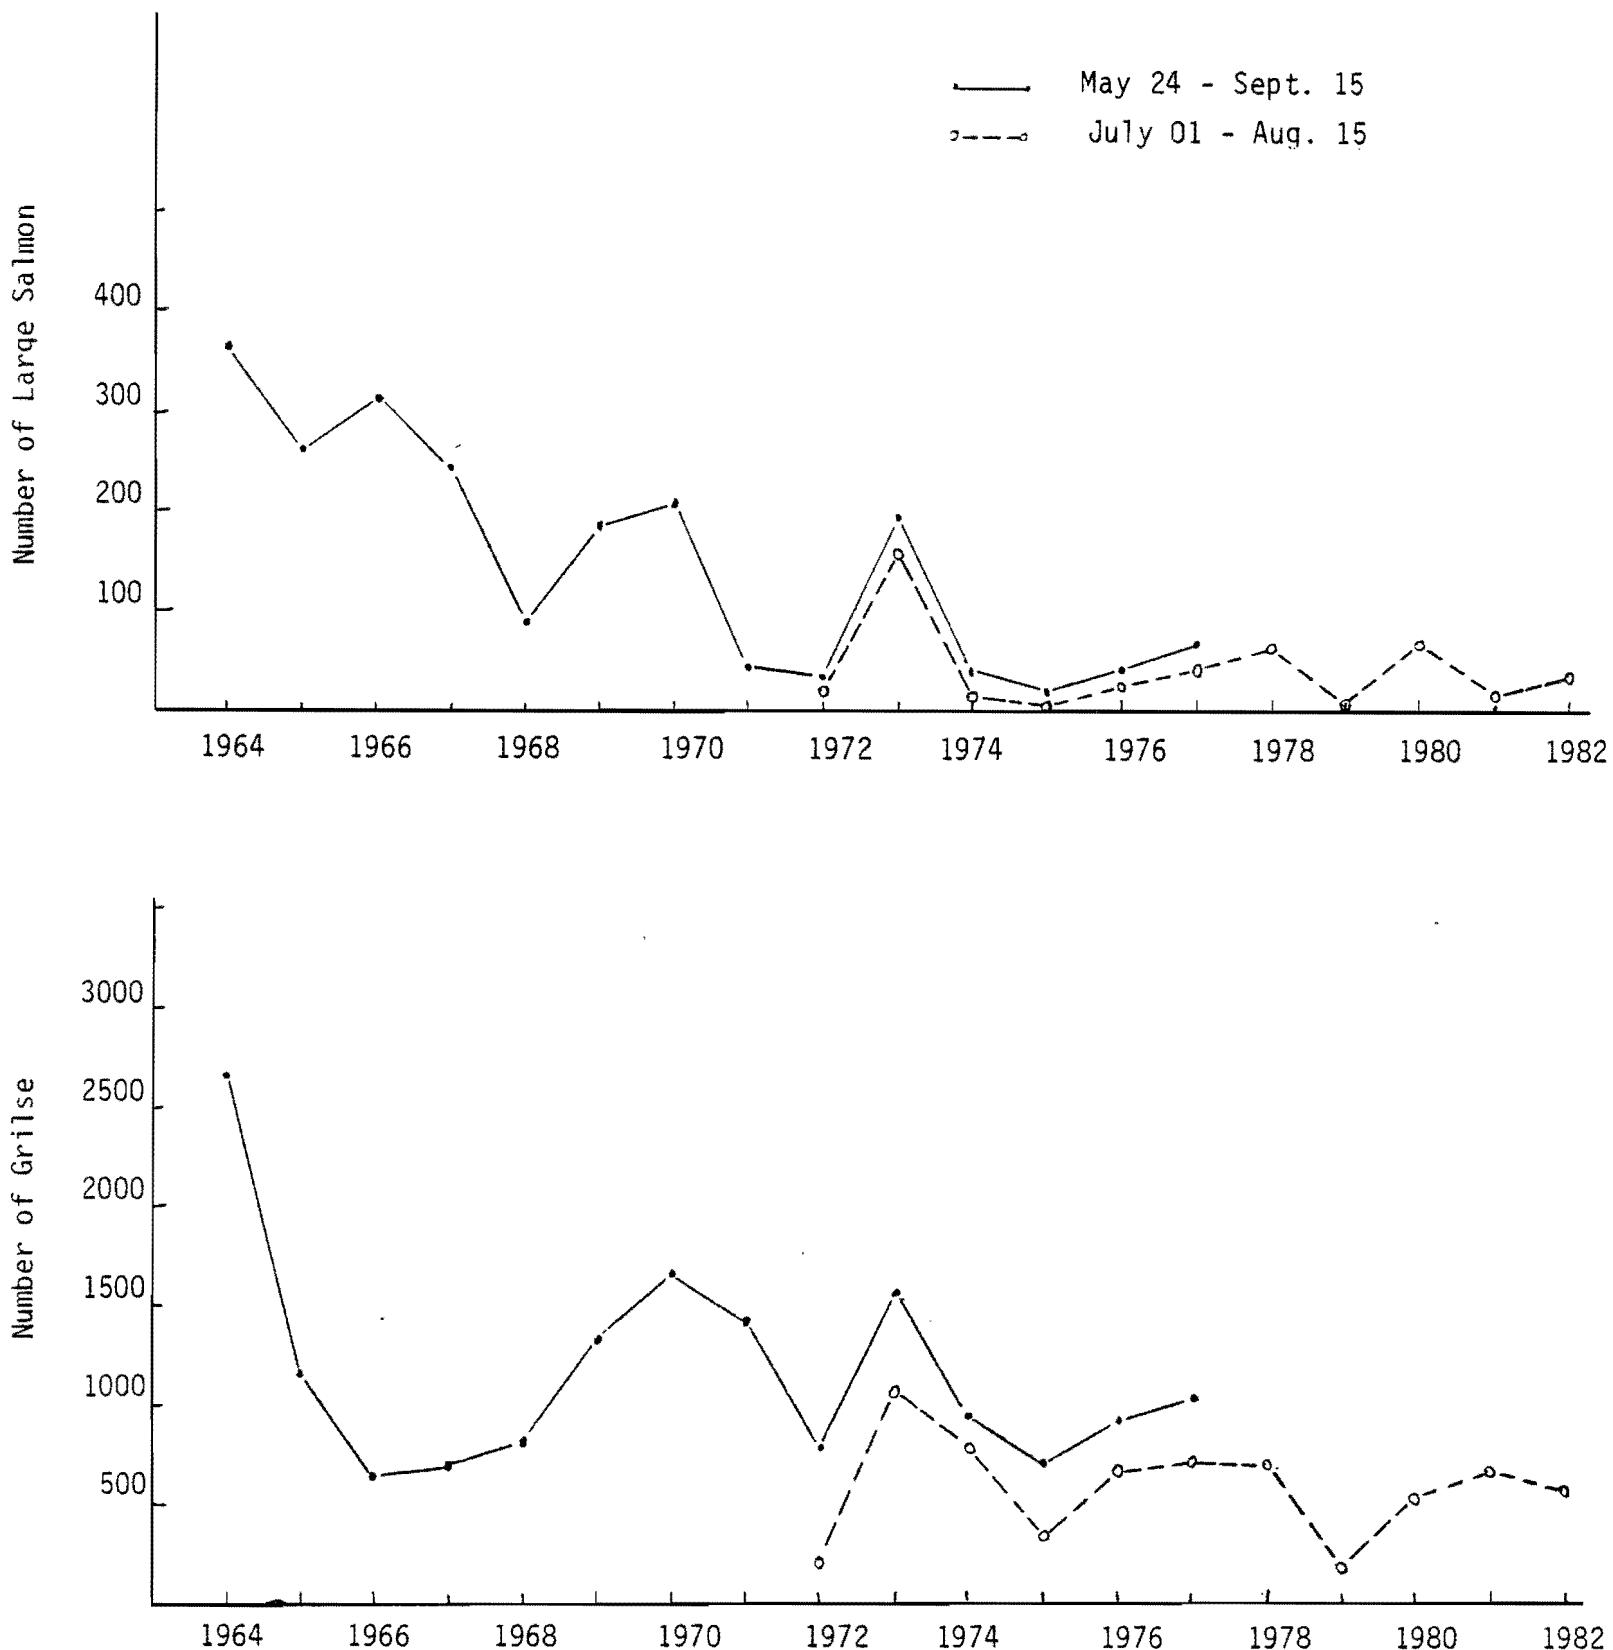

Fig. 14. Angling catch of large salmon and grilse on Harry's River May 24 - Sept. 15 (1964-1977) and July 01 - August 15 (1972-1982).
