# 1997 EVALUATION OF THE STOCK STATUS OF 4WX.HERRING 

R.L. Stepheñson, M.J. Power, F.J. Fife, G.D. Melvin and S.D. Paul

Marine Fish Division<br>Maritimes Region, Science Branch<br>Biological Station<br>St. Andrews, New Brunswick E0G 2X0

${ }^{1}$ This series documents the scientific basis for the evaluation of fisheries resources in Canada. As such, it addresses the issues of the day in the time frames required and the documents it contains are not intended as definitive statements on the subjects addressed but rather as progress reports on ongoing investigations.
${ }^{1}$ La présente série documente les bases scientifiques des évaluations des ressources halieutiques du Canada. Elle traite des problèmes courants selon les échéanciers dictés. Les documents qu'elle contient ne doivent pas être considérés comme des énoncés définitifs sur les sujets traités, mais plutôt comme des rapports d'étape sur les études en cours.

Les documents de recherche sont publiés dans la langue officielle utilisée dans le manuscrit envoyé au secrétariat.

#### Abstract

The 4WX management area contains a number of herring spawning areas which are grouped for assessment and management into three units: Southwest Nova Scotia/Bay of Fundy, Offshore Scotian Shelf Banks, and Coastal (South Shore, Eastern Shore and Cape Breton) Nova Scotia spawning components. In addition there are migrant herring from neighboring units, including juveniles taken in the Bay of Fundy (New Brunswick) weir fishery.

The SW Nova Scotia spawning component has declined in recent years. Landings in 1996 were the lowest in three decades, reflecting the lowest quota on record for this fishery. The fishery exhibited a poor age composition, dominated by a single (1992) year-class. Continuation of "in-season" management led to over 800 hrs . of surveying by industry vessels. The $190,000 \mathrm{t}$ of spawning herring documented in this way was used as an estimate of minimum SSB. A sequential population analysis calibrated with larval abundance indicated about $300,000 \mathrm{t}$, but was considered a poor estimate of stock size, due to a weak fit to the tuning index.

Most of the 4VWX Coastal Nova Scotia spawning component suffers from poor documentation of the fishery (especially bait landings) and insufficient information to assess stock status. A study of the Bras D'Or Lakes spawning component suggests a decline in stock status.

## Résumé

La zone de gestion 4WX abrite diverses zones de frai du hareng qui sont regroupées, à des fins d'évaluation et de gestion, en trois unités : le sud-ouest de la Nouvelle-Écosse et la baie de Fundy; les bancs du large du plateau néo-écossais et la zone côtière de la Nouvelle-Écosse (côte sud, côte est et Cap-Breton). On compte aussi des harengs en migration d'unités voisines, dont des juvéniles capturés par les pêcheries fixes de la baie de Fundy (Nouveau-Brunswick).

La composante de frai du sud-ouest de la Nouvelle-Écosse s'est appauvrie au cours des années. Les débarquements de 1996 ont été les plus faibles des trois dernières décennies et reflètent le quota le moins élevé jamais accordé pour cette pêche. Le stock ne présentait par une bonne composition par âges, les captures étant dominées par une seule classe d'âge (1992). Le maintien de la gestion « en cours de saison » a donné lieu à plus de 800 heures de relevés par des bateaux de l'industrie. Les géniteurs ainsi dénombrés, dont le volume atteignait 190000 tonnes, ont été utilisés pour estimer une biomasse minimum du stock de géniteurs. Une analyse séquentielle de population étalonnée par l'abondance larvaire donne une valeur de 300000 tonnes environ, mais cette valeur de la biomasse du stock est considérée comme peu valable à cause d'une mauvaise concordance avec l'indice d'ajustement.

La plus grande partie de la composante de frai de la zone côtière de la Nouvelle-Écosse de 4VWX se caractérise par un manque de renseignements sur la pêche (notamment des débarquements destinés à servir d'appâts) et de données pour l'évaluation de l'état du stock. Une étude de la composante de frai aux lacs Bras d'Or porte à croire à un déclin du stock.

## Background and Context

The 1996 fisheries were undertaken within a context of biological uncertainty and concern. The 1996 stock status evaluation based on the 1995 fishery (Anon 1996; Stephenson et. al. 1996), confirmed the view of the previous year that the SSB of the major SW Nova Scotia spawning component had decreased substantially since a high in 1989, and the current stock size was uncertain. Observations from the 1995 fishery, while improved over the previous year, were mixed. Of concern was the reliance on recruiting yearclasses, the lack of fish in one traditional spawning area (Seal Island), and lack of aggregations in some traditional summer feeding and pre-spawning areas. The evaluation indicated an SSB in 1996 of 100,000 to 200,000 $t$ (for the SW Nova spawning component). The TAC for this portion of the fishery was reduced further, to $50,000 \mathrm{t}$ for 1996 (although $57,000 \mathrm{t}$ was allocated) - only one third of what it had been two years earlier (1994), and the lowest ever for this fishery. Management extended the initiatives of in-season management, and of management of individual spawning components, so as to be able to react quickly and appropriately to signals from the fishery.

The year also saw considerable changes in fishing pattern. There was further exploration by the purse seine sector of herring on offshore ( $>25 \mathrm{mi}$.) Scotian Shelf Banks. There was also a considerable expansion of the gillnet fishery, including the re-emergence of the SW Nova Scotia gillnet fishery and the initiation of a gillnet roe fishery east of Halifax.

## Stock Structure and Management units

Biological evaluations and management are based on management of complex populations/stocks. While it has long been recognized that there is additional structure within management units, there is increasing awareness of the need to extend management consideration to the individual spawning group level. Recent history in SW Nova Scotia, has shown the problem of disproportionately high effort applied to one component of a stock complex (e.g. depletion of the Trinity Ledge spawning group). There is considerable concern within the industry over what is seen as the potential erosion of spawning components. There is the real possibility of sequential erosion of spawning groups within management complexes, while apparently remaining within an overall safe fishery limit. Persistence of the full diversity of spawning stocks within each management unit must be a principle of management. The challenge is to develop management approaches which are able to ensure the maintenance of all spawning components at sustainable levels. This is complicated by the fact that some spawning areas are not well documented.

The area covered by the 4WX management unit is known to contain a number of spawning areas separated to various degrees in space and time. Spawning units in close proximity, with similar spawning times, and which share a larval distribution area (e.g. Trinity Ledge and German Bank in SW Nova Scotia) are considered part of the same complex - and undoubtedly have much closer affinity than spawning units which are widely separated in
space or time, and do not share a common larval distribution (e.g. SW Nova autumn spawners vs. Bras d'Or Lakes spring). Some of these are large and offshore (e.g. German Bank), whereas others are small, and more localised spawning locations, sometimes very near shore in small embayments (e.g. Advocate, N.S.). The situation is complicated further by the fact that herring tend to migrate long distances, and to mix with members of other spawning groups outside of the spawning season. Further, some spawning areas, (such as Trinity Ledge, German Bank) are known from fishery sampling; tagging, etc. to hāve formed the basis for major historical fisheries, while others have not.

The purposes of this evaluation, the 4WX fisheries are divided into four components:

## A) SW Nova Scotia spawning component:

Based on major spawning areas off SW Nova Scotia, this component has formed the basis for the large "stock" fishery, managed under TAC for many years. Fishing has taken place on the spawning grounds, on these fish in pre-spawning and feeding aggregations, and historically on the same fish (demonstrated by tagging) in overwintering areas in eastern Nova Scotia.

In the SW Nova Scotia fishery, an attempt is being made to spread the fishing effort among spawning groups in proportion to their relative size. A working group of the Scotia-Fundy Herring Advisory Committee (SFHAC) established in 1994 compiled biological and industry knowledge about the relative size of spawning groups, and led to the first, tentative breakdown of the summer quota among spawning areas. Since that time management has moved more and more to consideration of individual spawning units. In 1995 and 1996 there were sonar/sounder surveys of major spawning areas, and fishing was only allowed on a portion of what had been documented in each area.

## Current fishery segments

4Xqr (Bay of Fundy/SW Nova) summer purse seine
4Xs fall (Bay of Fundy) purse seine
4X (Bay of Fundy) midwater trawl
4X (SW Nova) summer gillnet
4X (Nova Scotia) summer weir
4W (Chedabucto Bay) winter purse seine
4X (Halifax) winter purse seine* (subject of debate)

## B) Coastal (South Shore, Eastern Shore and Cape Breton) Nova Scotia Spawning component:

Many spawning locations (both spring and fall) are known to have existed historically along the coast of Nova Scotia. They have been fished traditionally by inshore geartypes (gillnet, trap) for bait, subsistence use, and sale but are poorly documented. These are presumed not
to have contributed to the traditional SW Nova Scotia fishery, and traditionally such these stocks have been excluded from the management plan.

## Current fishery segments:

4WX South Shore and Eastern Shore Nova Scotia trap and gillnet 4X (Halifax) winter purse seine* (subject of debate)

## C) Offshore (>25 mi.) Scotian Shelf Banks spawning component:

Herring were taken on the offshore Scotian Shelf by foreign fisheries prior to the extension of jurisdiction, when these fish were presumed to be part of an overall 4WX stock. Evidence of increasing presence of herring (e.g. in research vessel surveys) and of spawning offshore within the past decade has suggested that there is a discrete offshore spawning component.

The presence of spawning herring in catches in 1986 and of larvae in scientific surveys (1991-93), the consistent presence of large herring on the Scotian Shelf in summer trawl surveys, and broad age distribution of the catch are all consistent with the separate management treatment of the offshore banks.

## Current fishery segments:

4WX (offshore) purse seine
D) SW New Brunswick migrant juveniles:

The SW New Brunswick weir and shutoff fishery has relied, for over a century, on the aggregation of large numbers of juveniles in that area of the mouth of the Bay of Fundy. These have traditionally been considered to be a mixture dominated by fish originating from Subarea 5 spawning components.

## Current fisheries:

4X (NB) weir and shutoff (juveniles only)

## Management changes

Finalization of the management plan for the 1996 fishery was delayed until late spring in order to incorporate the results of the 1996 stock status evaluation.

An "in-season" management approach has been implemented in the 4WX herring fishery during the past two years. Under this approach a number of decisions within the overall management plan have been delegated to a team, made up of participants in the fishery and members of DFO, to be made during the season on the basis of the best available information. Observations from the fishery have been monitored and discussed routinely so that management could be modified quickly according to negative or positive signals from the fishery. Decisions have related primarily to the spatial and temporal distribution of fishing within the quota. In particular, there has been an attempt to ensure that fishing has been distributed appropriately among various components of the stock (particularly among spawning components) according to the relative size and current state of each component.

In-season management has resulted in an increase in the quantity, quality, and availability of information from the fishery. Surveys have been implemented, sampling has increased, and data handling procedures have been changed to allow more rapid summary of results. Several segments of the fishery have operated under a cautious "survey, assess, then fish" protocol, in which preconditions had to be met before that part of the fishery was allowed to take place. This demanded a very high level of commitment, involvement and cooperation from all participants in the fishery management process, and led to improved effectiveness of management and care for the resource.

## Landings in the 1996 4WX fisheries

Total of $87,443 \mathrm{t}$ was recorded in the 1996 calendar year from the combined 4WX fisheries (Table 1).

Landings from the SW Nova Scotia component were $(58,068 t)$ were the lowest in three decades (Table 2), as a result of the low quota.

Landings by gillnet and trap along the coast of Nova Scotia included a new fishery on spawning fish east of Halifax ( 1296 t , October). The relatively small amount of additional landings recorded (192 t) is thought to be the result of a problem with landings documentation especially in the bait fishery.

Purse seine activity on the offshore Scotian Shelf resulted in landings of $11,745 \mathrm{t}$.
The NB weir and shutoff fishery total of $15,913 \mathrm{t}$ was well below average (about 25,000 t) and continued a decline since 1992.

## Biological Sampling

The distribution of samples is summarized in Table 3. As in other years sampling was conducted by St. Andrews Biological Station staff at sea and in port sampling, other

DFO port sampling staff, observers, vessel crew and processing plant staff. However, the level of biological sampling increased in 1996 as the result of a new collaborative initiative with the processing sector. At the invitation of members of the herring processing industry, a new program of biological sampling by industry personnel was developed and implemented at major herring processing facilities in the Scotia-Fundy area. In this program, all commercial landings of herring at participating plants in New Brunswick and Nova Scotia were sampled by plant employees for length and subsamples taken for further analysis according to criteria established by DFO. Most samples, in this first experimental year, were collected in NAFO area 4Xs (along the coast of southwest N.B.) due to the early participation and comprehensive coverage by Connors Bros. Ltd. plants in that area but other areas received enhanced sampling coverage later in the fishing season.

## A) SW Nova Scotia/Bay of Fundy Spawning Component

## 1996 fishery

The TAC for this component was reduced from $80,000 \mathrm{t}$ in 1995 to $50,000 \mathrm{t}$ in 1996. Although $57,000 \mathrm{t}$ was allocated, it was still the lowest quota ever for this fishery. An "inseason" management scheme first implemented in the 4WX herring fishery during 1995 encouraged survey and evaluation prior to fishing to ensure that fishing was distributed appropriately among various components of the stock (particularly among spawning components) according to the relative size and current state of each component. This was continued, and extended in 1996, so as to be able to react quickly to signals from the fishery.

As a result of the low quota, landings from the SW Nova Scotia component (58,068 t) were the lowest in three decades. The amount taken by purse seine and a single midwater trawl $(48,252$ t) was the lowest since 1979 . For the first time in several years, a substantial quantity ( 6340 t ) was taken by gillnet. Nova Scotia weirs took 3,476 t, continuing an increasing trend which began in 1991.

In-season management has resulted in an increase in the quantity, quality, and availability of information from the fishery. Surveys have been implemented, sampling has increased, and data handling procedures have been changed to allow more rapid summary of results. Several segments of the fishery have operated under a "survey, assess, then fish" protocol, in which predefined conditions had to be met before that part of the fishery was allowed to take place.

The distribution of herring as reflected by the fishery during summer feeding and prespawning period seemed normal. Surveys and fishing showed good abundance of herring on Scots Bay, and German Bank spawning grounds, and the return of spawners to Trinity Ledge and Lurcher Shoal. There was an absence of spawning, however, at Seal Island,
and low abundance in the overwintering area of Chedabucto Bay, where only $2,000 \mathrm{t}$ was taken.

## Catch at age

The 1992 year-class (age 4) dominated all fisheries on the SW Nova Scotia spawning component except for midwater trawl (Table 4). The 1992 year-class made up a disproportionately large portion of the catch by number ( $61 \%$ ) and weight ( $60 \%$ ). It was followed in relative importance by the 1991 year-class (age 5) at $13 \%$ by number and $16 \%$ by weight. These same year-classes had also dominated the 1995 fishery. The dominance of a single year-class in this fishery is quite different from the usual more balanced age distribution (as shown in the average of 1986-95) and from lightly fished areas nearby (coastal Nova Scotia (Table 5), offshore Scotian Shelf banks (Table 6)), and is considered an undesirable situation.

Although there was fleet avoidance of younger fish (because of the low quota), the 1993 year-class was poorly represented in the catch, and may be weak. The relatively low proportion at age 2 in the catch may indicate that the 1994 year-class, which originated in the year of the warm water temperature anomaly and extremely low larval herring abundance, is also relatively weak.

## Research and survey data

i) Larval abundance

The larval abundance index, as traditionally calculated, was 9.5 (larvae per m 2 ); lower than that of 1995 , but above that of 1994 which was the lowest observed since 1981 (Table 7). An initial attempt was made to improve the use of the larval abundance index in tuning by partitioning the index according to the age composition in the spawning stock, and this warrants further investigation.
ii) In-season surveys

Building on trials undertaken in 1995, an expanded series of surveys was undertaken of major spawning areas and some other major fishing areas using commercial vessels. Sonars and sounders were used by both the purse seine and later the gillnet fleet to document number, location and approximate size of herring schools. In the most successful of these surveys, many vessels worked together to provide comprehensive coverage of the target areas. During 1996 almost 800 hours of surveying was undertaken by industry vessels: 610 hours by the purse seine sector, and 180 hours by the gillnet sector. The 13 surveys undertaken on spawning grounds of the SW Nova component documented $190,000 \mathrm{t}$ of spawning herring. Survey methods are still under development, and more quantitative rigor is required in several aspects of these surveys, however they were considered to represent a
minimum biomass estimate. Surveys did not cover the entire spawning season or all spawning locations, and conservative density values were used in contouring.

| Spawning <br> Area | Survey <br> Date | Estimated <br> Biomass (t) |
| :--- | ---: | ---: |
| Scots Bay | 24-Jul-96 | 1,000 |
|  | 31-Jul-96 | 43,000 |
| Trinity Ledge | 14-Aug-96 | 3,300 |
|  | 27-Aug-96 | 10,400 |
|  | 5-Sep-96 | 10,500 |
|  | 11-Sep-96 | 5,000 |
| Lurcher Shoal | 24-Sep-96 | 18,000 |
|  |  |  |
| German Bank | $28-A u g-96$ | 8,000 |
|  | $11-$ Sep-96 | 12,800 |
|  | 30-Sep-96 | 74,000 |
| Seal Island |  |  |
| Spectacle Grounds | 11-Sep-96 | 2,500 |
|  |  |  |
|  |  | 11-Sep-96 |

Total biomass
195,000

## Population analysis

An analytical assessment, similar in structure to that used in the previous two assessments was attempted. Larval abundance was related to spawning stock biomass (SSB) from which the larvae were derived. The analysis (Appendix 1) suggests a SSB of about $300,000 \mathrm{t}$, but there is large uncertainty in parameter estimates due to weak fit to the tuning index, especially in the last three years, and there was concern that the predicted population estimate was too high.

The analytical assessment (considered to be an overestimate), and the $190,000 \mathrm{t}$ documented in survey (considered a minimum) were thought to bracket the actual SSB.

## Major Sources Of Uncertainty

At present, there is a lack of a reliable indicator of abundance for this stock. There have been difficulties using the larval abundance index, and there is no other time series. The sudden drop in larval abundance index in 1994, and relatively low values of the last three years compared to the previous three years is difficult to explain. Acoustics, although promising, are under development. There is need for improved quantification and objectivity in industry acoustic (sonar/sounder) surveys.

Outlook

The fishery continues to rely primarily upon a single year-class (1992) and recruiting year-classes (1993 and 1994) may be relatively weak. There is a need to rebuild spawning stock biomass and to broaden age structure in the population and therefore it is appropriate to fish below the F0.1 level for several years. A fishery at the status quo catch ( $57,000 \mathrm{t}$ ) is considered unlikely to exceed F0.1 reference levels, but may result in a decrease in SSB if recruitment is poor. The in-season management approach should help protect individual spawning areas.

## Ecosystem Considerations

Herring is a prominent species in the diets of many other fish, birds, and marine mammals, and should be managed with these interactions in mind. At present, a natural mortality rate of 0.2 is assumed to account for these interactions. Low fat content and poor condition in herring observed in 1994, thought to be related to an environmental anomaly, have not been observed since that time.

## Management Considerations

In 1996, $20 \%$ of surveyed biomass was used as the target percentage in the "survey, assess, then fish" protocol. This target harvest percentage on spawning grounds should be reviewed, to take into consideration the harvest of those spawners taken outside of the spawning season.

## B) 4VWX Coastal (South Shore, Eastern Shore and Cape Breton) Nova Scotia Spawning component:

## The Fishery

Although the fishery operates throughout coastal waters of 4VWX, very limited information is available except in two areas. Landings by gillnet and trap along the coast of Nova Scotia included a new fishery on spawning fish east of Halifax ( 1300 t , October) and a well documented fishery in the Bras D'Or Lakes (spring, 170 t ). The relatively small amount of additional landings recorded from the remainder of the coast (190 t) is thought to be the result of poor catch reporting, for a considerable amount of herring is known to have been landed for bait and local use. There is a large latent effort in the gillnet sector. The 2000 licenses on record for 1996 allow almost 1000 miles of gillnet to be set. Records indicate that fewer than 200 licenses were active in 1996; however, this is a substantial increase from the $30-40$ which were active over the past seven years.

The winter purse seine catches off Halifax in the past two years contained mostly small, overwintering fish, which may have included fish from this coastal spawning component.

## Resource Status and Outlook

A specific study of herring, and the herring fishery, in the Bras D'Or Lakes began in 1996. The fishery of approximately 170 t was dominated by the 1989 (age 7) and 1988 (age 8) year-classes. The 1990 and 1991 year-classes were poorly represented in the catch, and may be relatively weak. A survey of fishers indicated that there had been a decrease in abundance of herring in the lakes in recent years, that spawning in 1996 was restricted to only a few of the traditional spawning grounds, and that fishing effort had increased and become more concentrated.

The new gillnet fishery east of Halifax took fish with a broad age distribution. The catch was dominated by 1990 and 1989 year-classes (ages 6 and 7), but had high proportion of age $11+$. An industry survey of the area in October estimated about $40,000 \mathrm{t}$.

Aside from the two areas mentioned above, there is little information, and no basis for evaluation of these stocks.

## Management Considerations

There is concern that the winter purse seine fisheries near the coast may take an unknown proportion of fish from this component, along with overwintering fish from other areas, at some times and places. This issue is discussed in more detail in a 1997 Fishery Status Report entitled "Decision rules for management of overwintering fisheries" (Anon 1997).

The reduction in spawning areas, and increase in effort in the Bras D'Or Lakes are cause for concern. Effort in the Bras D'Or Lakes commercial and bait fisheries should be reduced, so as to reduce landings of this spawning group.

No coastal spawning area should have a large effort increase until much more information is available on the state of that spawning group. There should be no new fisheries developed when there is uncertainty regarding stock composition and degree of mixing.

There is urgent need for improvement of the monitoring of existing fisheries and documentation of spawning groups.

## C) Offshore (>25 mi.) Scotian Shelf Banks spawning component:

## The Fishery

A foreign fishery during the period 1963-1974 is estimated to have taken as much as $60,000 \mathrm{t}$ in a single year from the offshore Scotian Shelf banks (Stephenson et. al. 1987). Since the extension of jurisdiction, there has been little herring catch or effort. The 1996 fishery began May 22, and continued to June 24. Landings of $11,750 \mathrm{t}$ were primarily from "The Patch" located approximately 50 mi . southeast of Halifax, with some catch from other banks.

## Resource Status and Outlook

The 1996 landings from the offshore banks had a broad age distribution, dominated by the 1992 year-class (age 4), followed by the 1989 year-class (age 7) (Table 6). A single industry sonar/sounder survey in June 1996 covered a large area, but documented only a moderate amount of herring on Emerald/Western banks and a dense aggregation on French Bank (located about 30 mi . south of Country Harbour).

Although insufficient information is available to evaluate stock size, there have been several encouraging signs regarding the state of herring on offshore banks. The July research bottom trawl survey showed little herring on the Scotian Shelf during the late 1970's and early 1980's, increasing amounts during the late 1980's and relatively widespread distribution in recent years (Fig. 1; Table 7). Spawning was documented in industry samples from Western Bank in 1986, and larvae have been present in occasional ichthyoplankton surveys.

## Management Considerations

Foreign fisheries took relatively large amounts (as much as $60,000 \mathrm{t}$ in a year) from the offshore Scotian Shelf banks during the period 1963-1973. These fisheries did not sustain large catches over a number of years and the average recorded catch for the 1970-73 period was $30,000 \mathrm{t}$. Industry, science and management are encouraged to work together to develop a medium term strategy for assessment and exploitation of the herring on the Scotian Shelf outer banks.

## D) SW New Brunswick migrant juveniles:

## The Fishery

The 1996 catch $(15,900 t)$ in weir and shutoff fisheries was below average and the lowest on record since $1984(8,700 \mathrm{t})$. The decline in catch is thought to be the product of a decrease in the number of active weirs and a lack of fish available to the gear. Purse seiners fishing in the Grand Manan area in 1996 observed substantial amounts of juvenile (ages 2 and 3) herring. Landings from this fishery are included in the U.S. coastal Maine complex (Subarea 5) which is considered to be at high abundance.

Resource Status and Outlook

There has been a $50 \%$ decline in total catch in the past 3 years which may be cause for concern. Catch at age has been dominated, as in previous years, by age $2(86 \%$ number; $70 \%$ weight) with some age one, three, and a few older ages (4+) (Table 8).

No separate evaluation of this fishery was made.

* Reported landings against the annual plan quotas (shaded blocks) correspond to catches made in the seasonal periods (Notes 1-5).
** Non-Stock totals are for the calendar year January 1, 1995 to December 31, 1995.

## NOTES

| 1. Quota period is November 1,1995 to March 1, 1996 |  | 4. Quota period is April 1, 1996 to October 15, 1996 |
| :---: | :---: | :---: |
| 2. Quota period is October 15, 1995 to December 31, 1995 |  | 5. Inshore/Fixed and Misc Gear allocation is for the calendar year. |
| 3. Quota period is January 1, 1996 to February 28, 1996 | 1 | 6. Predominantly from Halifax area in Jan. 1996 |

^Annual landings by purse seiners are defined for the annual plan period from October 15 of the preceding year to october 14 of the current year.
All landings by other geartypes are for the calendar year

* Includes 4 Xs stock catches taken by single midwater trawl, and 4 wX stock catches by gillnets, traps, foreign trawlers, and miscellaneous gears.
** Adjusted totals includes misreporting adjustments for 1978-1984 (Mace 1985).
