#### Abstract

An angling-based assessment assuming 30-50\% exploitation indicated that egg deposition and large salmon spawning escapement were about $35-65 \%$ of the conservation requirement for the Restigouche River. Visual counts estimate that large salmon escapement was approximately $40-50 \%$ of requirement and support the conclusion of the angling-based assessment that small salmon spawning escapement was in excess of the requirement. All indices of abundance indicated that returns to the river were low in 1997. Returns to counting fences on the Matapedia and Upsalquitch rivers were $36-38 \%$ below the five-year mean return of large salmon but only $5 \%$ (Upsalquitch River) below the mean of small salmon. Total returns of large salmon to the river did not exceed the conservation requirement.

Estimated returns by the angling catch-based method were 7,400-11,700 large and 7,90013,200 small salmon. By a combination of the visual methods, returns were conservatively estimated at a minimum of 7,300 large and 6,000 small salmon. Angling catches (retained+released) were 2,649 large and 3,408 small salmon. Retained angling harvests were 729 large and 3,079 small salmon. New Brunswick First Nations harvest was at least 166 large and 26 small salmon. Québec First Nation harvest was unknown but was estimated as 985 large and 18 small salmon.

Based on a significant historical correlation of small salmon returns in year x to large salmon returns in year $x+1$ in the Matapedia River, and on the basis of average small salmon returns to the Restigouche River in 1997, there may be an expectation of average 2 -sea-winter salmon returns in 1998. However, this expectation must be regarded with caution given the low returns of large salmon in the Restigouche system in 1997.

Densities of juvenile age classes, determined by electrofishing, were $7-29 \%$ above the fiveyear means.

Conservation requirements and stock assessments of the five major tributaries of the Restigouche system are presented here for the first time. According to visual surveys by divers, none of the stocks achieved egg deposition at the level of $2.4 \mathrm{eggs} / \mathrm{m}^{2}$. Egg depositions of the Little Main Restigouche and Matapedia stocks were estimated at $84-86 \%$ of the conservation requirement. Kedgwick, Upsalquitch and Patapedia egg depositions were estimated at from a bit under half to about three quarters ( $43-73 \%$ ) of the requirement. This estimate may be overly conservative for the Patapedia and Upsalquitch because of incomplete spatial coverage by the surveys in these rivers.

Large salmon returns in excess of spawning escapement requirements occurred only in the Matapedia River. Small salmon returns to all the tributaries were in excess of spawning escapement requirements.

## Résumé

Une évaluation fondée sur les données de la pêche récréative à un taux d'exploitation présumé de 30 à $50 \%$ indique que la ponte et l'échappée de gros saumons satisfaisaient entre 35 et $65 \%$ des besoins de conservation pour la rivière Ristigouche. Les dénombrements situent l'échappée estimative de gros saumons comme correspondant à environ 40 à $50 \%$ des besoins et étayent la conclusion de l'évaluation fondée sur la pêche récréative à l'effet que l'échappée de petits saumons dans la rivière était faible en 1997. Les remontées observées aux barrières de dénombrement des rivières Matapédia et Upsalquitch étaient de 36 à $38 \%$ inférieures à la remontée moyenne quinquennale de gros saumons, mais de seulement $5 \%$ (rivière Upsalquitch) inférieure à la remontée moyenne de petits saumons. Les remontées totales de gros saumons dans la rivière n'étaient pas supérieures aux besoins de conservation.

Les remontées estimées selon la méthode des prises récréatives atteignaient entre 7400 et 11700 gros saumons et entre 7900 et 13200 petits saumons. Une combinaison des méthodes d'observation visuelle donne une estimation prudente d'un minimum de 7300 gros saumons et de 6 000 petits saumons. Les prises récréatives (saumons conservés + saumons remis à l'eau) se situaient à 2629 gros saumons et 3408 petits saumons. Les prises gardées se composaient de 729 gros saumons et de 3079 petits saumons. Les Premières nations du Nouveau-Brunswick ont capturé au moins 166 gros saumons et 26 petits saumons. Les prises des Premières nations du Québec sont inconnues, mais elles sont estimées comme se situant à 985 gros saumons et 18 petits saumons.

D'après une étroite corrélation historique entre les remontées de petits saumons dans l'année x et les remontées de gros saumons dans l'année $\mathrm{x}+1$ dans la rivière Matapédia et étant donné que les remontées moyennes de petits saumons dans la rivière Ristigouche en 1997 étaient dans la moyenne, on pourrait s'attendre à des remontées moyennes de saumon dibermarin en 1998. On ne doit toutefois pas donner trop de poids à cette attente étant donné les faibles remontées de gros saumons dans le réseau de la Ristigouche en 1997.

Les densités des juvéniles selon les classes d'âge, déterminées par pêche électrique, étaient de 7 à $29 \%$ supérieures aux moyennes quinquennales.

Les besoins de conservation et les évaluations des stocks des cinq principaux tributaires du réseau de la Ristigouche sont présentés pour la première fois. Selon des relevés visuels effectués par plongée, aucun des stocks n'a réalisé une ponte à 2,4 oeufs $/ \mathrm{m} 2$. La ponte chez les stocks de la Petite Ristigouche principale et de la Matapédia a été estimée comme se situant à entre un peu moins de la moitié à environ trois quarts ( $43-73 \%$ ) des besoins. Cette estimation peut être trop prudente dans le cas des rivières Patapédia et Upsalquitch car la couverture spatiale des relevés de ces cours d'eau était incomplète.

Les remontées de gros saumons excédentaires aux besoins de l'échappée ne se sont manifestées que dans la rivière Matapédia, tandis que les remontées de petits saumons dans tous les tributaires dépassaient les besoins de l'échappée.

## 1 - Introduction

The objective of this report is to evaluate the status of Atlantic salmon in the Restigouche River system in 1997. Numbers of spawners in the entire system are estimated from (1) angling data and exploitation rates estimated to represent lower and upper limits, and (2) visual surveys of spawners. New to this stock assessment are tributary-specific assessments and conservation requirements for the five major tributaries of the Restigouche.

In the terminology of this report, small salmon are adults less than 63 cm in fork length, which are comprised mainly of 1SW (one-sea-winter or grilse) maiden salmon. Large salmon (also known as MSW or multi-sea-winter salmon) are adults greater than or equal to 63 cm in fork length. This category contains mainly maiden 2SW and 3SW fish and previous spawners.

## 2 - Conservation requirements

The egg deposition requirement for conservation of Atlantic salmon in the Restigouche River system is based on a recommendation for $2.4 \mathrm{eggs} / \mathrm{m}^{2}$ of accessible habitat (Elson 1975). Habitat is estimated as $29.8 \times 10^{6} \mathrm{~m}^{2}$ and therefore the requirement is $71,443,200$ eggs (Randall 1984). Biological characteristics of salmon sampled in the estuary of the Restigouche River indicate that approximately 12,200 large salmon are required to produce these eggs. An additional 2,600 small salmon are required to ensure a 1:1 sex ratio at spawning (Randall 1984).

A new feature of this stock assessment is the calculation of conservation requirements for each of five major tributaries: the Kedgwick, Little Main Restigouche, Patapedia, Upsalquitch and Matapedia rivers (Table 1). Methodology followed Randall (1984), but biological characteristics specific to the stock of each tributary were used. Conservation requirements were not determined for the Main Restigouche River because biological characteristics specific to salmon which spawn in the main stem have not been measured. Tributary-specific conservation requirements, at a recommended egg deposition rate of $2.4 \mathrm{eggs} / \mathrm{m}^{2}$, were as follows:

| Tributary | Accessible <br> habitat $\left({\left.\mathrm{x} 10^{6} \mathrm{~m}^{2}\right)}\right)$Eggs <br> $\left(\times 10^{6}\right)$ | Large <br> salmon | Small <br> salmon |  |
| :--- | :--- | :--- | :--- | :--- |
| Kedgwick | 2.872 | 6.89 | 933 | 305 |
| Little Main Restigouche | 2.243 | 5.38 | 984 | 220 |
| Patapedia | 1.486 | 3.57 | 622 | 131 |
| Upsalquitch | 4.205 | 10.09 | 1839 | 970 |
| Matapedia | 6.811 | 16.35 | 2395 | 504 |

MEF has its own requirements for the Matapedia River and the Québec and New Brunswick (main stem) portions of the Patapedia River at a recommended egg deposition rate of $1.68 \mathrm{eggs} / \mathrm{m}^{2}$ of accessible habitat: these are 11.44 million and 2.33 million eggs, respectively. The use of 1.68 eggs $/ \mathrm{m}^{2}$ is equivalent to considering $70 \%$ of the accessible habitat to be rearing habitat, at an egg deposition rate of $2.4 \mathrm{eggs} / \mathrm{m}^{2}$ (F. Caron, MEF, pers. comm.).

## 3 - Restigouche system

## 3.1 - Description of fisheries

Restigouche salmon were fished by recreational anglers and First Nation communities.
Recreational angling was permitted in all tributaries and the main stem from June 1 to September 30 (except for Québec waters of the Patapedia River, where the season closed August 31). In addition, part of the Causapscal River and all New Brunswick and boundary waters were opened from May 15-31 for hook-and-release angling only (other than the Causapscal River, where fish were retained). Similar restrictions (which, in the Matapedia River, involved only large fish) applied to waters open to angling during September (except for Québec waters of the Kedgwick River, where retention was permitted). The Upsalquitch River was closed to all harvests from September 10 because of conservation concerns.

Anglers in New Brunswick tributaries and provincial boundary waters were required to release all large salmon. Catches of small salmon by New Brunswick license holders were restricted by seasonal (eight fish) and daily (two fish) bag limits. New Brunswick license holders angling in provincial boundary waters were regulated by Québec seasonal (seven fish) and daily (one fish) bag limits. However, for all intents and purposes the daily bag limit for New Brunswick anglers in provincial boundary waters was two small salmon, since Québec regulations permitted retention of a second salmon when the first fish caught in a day was a small salmon. Anglers licensed in Québec and fishing in Québec tributaries were allowed to retain both small and large salmon up to the daily and seasonal bag limits; if the first fish caught in a day was a small salmon, a second salmon of any size could be caught and retained.

Most salmon captured by First Nations fisheries were gillnetted in the estuary, although some angling also took place in freshwater portions of the river, primarily the Upsalquitch system. Gillnet fisheries were centred at Listuguj First Nation at Ristigouche, Québec, and at Eel River Bar First Nation near Dalhousie, N.B. (Fig. 1). No food-fishery trapnets were operated.

Eel River Bar First Nation's target harvest was set at 500 large and 50 small salmon to be harvested from Chaleur Bay, Crown Open waters of the Restigouche system, Benjamin River, Charlo River, Jacquet River and/or Eel River. The estuarine (Chaleur Bay) component of this harvest could be taken using up to 30 gillnets, each up to 400 ' in length, and up to three trapnets, during the season May 25 -December 31. Salmon were to be removed from other areas by angling only during the season June 1-December 31. Jigging was specifically excluded from this agreement. The gillnet fishery was carried out from mid-June to late July (Table 2), and the freshwater angling fishery occurred through the summer and autumn.

There was no harvest target for Listuguj First Nation. The fishing season agreed upon with the Québec government was June 6-July 22. In the interests of conservation, gillnet fishing was limited to five nights/week (allowing unobstructed passage of fish from 8 A.M. on Monday to 4
P.M. on Wednesday) and an area of the upper estuary immediately below the mouth of the river was designated as a conservation zone where gillnetting was not permitted.

Madawaska Maliseet First Nation fished upriver with a target harvest of 60 large and 190 small salmon to be taken from specified portions of the St. John, Green and Restigouche (Crown Open waters of the Main Restigouche, Kedgwick and Gounamitz rivers) watersheds. Angling was the only authorized means of harvest. This license covered April 25, 1997 to March 31, 1998.

The New Brunswick Aboriginal Peoples Council received a communal license with an allocation of 45 small salmon. These salmon were to be taken by angling only, from the waters of the Upsalquitch, Charlo, Benjamin and Jacquet rivers during August 1 through October 31; and from the waters of the Restigouche River (from the confluence of the Restigouche and Matapedia rivers for a distance of approximately 10 km upstream) during August 1 through September 15.

Pabineau First Nation received a communal license for 50 large and 40 small salmon, to be taken from the Upsalquitch, Charlo and/or Benjamin rivers from July 10 to December 31, 1997 and 10 small salmon, to be taken from the Jacquet River from June 3 to December 31, 1997.

Commercial salmon fisheries in Chaleur Bay have been closed in Québec since 1984, and in New Brunswick since 1985. Commercial fisheries in both provinces were prohibited from landing salmon caught in non-salmon fishing gear (by-catch).

## 3.2 - Fishery data

Fishery data were obtained from the sources listed in Appendix 6 of Claytor et al. (1994). No data were obtained from Listuguj First Nation in 1997, so the mean estuarine catch in 19891993 (the five most recent years for which data were available) was used as an estimate of harvest, as was also necessary in 1994-1996. It was assumed that there was no freshwater component to the Listuguj salmon harvest. The salmon harvest of Eel River Bar First Nation was subdivided into estuarine and freshwater components (R. Simonson, ERBFN councilor, pers. comm.). There was no harvest by Madawaska First Nation (F. Bernard, MMFN chief, pers. comm.) or N.B. Aboriginal Peoples Council (P. Fraser, NBAPC, pers. comm.). No data were obtained regarding Pabineau First Nation harvests.

Angling harvests (i.e., retained fish) were 729 large (Québec only) and 3,079 small salmon (Québec and New Brunswick combined) (Table 3). New Brunswick Aboriginal harvest was at least 166 large and 26 small salmon. Québec First Nation harvest was unknown but is assumed to be 985 large and 18 small salmon.

Angling catches were lower in 1997 than in 1996 (Table 4, Fig. 2). Small salmon angling catch was $5 \%$ lower than the five-year mean, but large salmon catch was $22 \%$ lower than the mean.

Large salmon catch per unit effort (CPUE) in 1997 was $26 \%$ lower than the five-year mean (Table 5). Small salmon CPUE was $14 \%$ lower than the mean.

Landings by New Brunswick Aboriginal communities were at least 26 small salmon and 166 large salmon, which were reported by Eel River Bar First Nation (Table 6). Madawaska Maliseet First Nation reported a catch of 0 salmon. Other aboriginal communities licensed to fish the Restigouche system did not report catch. Trends in Listuguj First Nation landings could not be determined; the estimated catch was 18 small and 985 large salmon. Recommendation: Harvest data is required from all fisheries; in particular, the salmon harvest of Listuguj First Nation evidently represents a large component of removals from this river, but these data have not been provided since 1993.

Total reported and estimated landings of salmon in the Restigouche system in 1997 were 5003 fish (Table 7).

## 3.3-Angling-based estimate of stock status

Total returns were considered to be the sum of estuary harvest, river harvest, poaching and disease (PAD) removals, and spawning escapement.

Returns $=$ Estuary harvest + PAD + River harvest + Escapement

Estuary harvest is First Nations harvest.
An adjustment for mortality resulting from poaching and disease is normally excluded from calculations of spawning escapement in other rivers since the conservation requirement of 2.4 $\mathrm{eggs} / \mathrm{m}^{2}$ takes this source of mortality into account. It has been retained in the assessment for the Restigouche River since in this system poaching and disease occurs prior to or at the same time as in-river removals and thus must be added to these to estimate returns.

The poaching and disease (PAD) mortality rate was assumed to be 0.14 of the population entering the river (i.e. after estuary harvest, but before angling) for small salmon and 0.16 for large salmon, as in previous assessments (Randall et al. 1988). The calculation was made as follows:

For large salmon, $\mathrm{PAD}=\mathbf{0 . 1 6}[\mathrm{B} / \mathbf{0 . 8 4}]$ because,
$\mathrm{PAD}=16 \%$ of the population at point A and,

The population at point $\mathrm{A}=\mathrm{B}+0.16 \mathrm{~A}$

$$
=\mathrm{B} / 0.84
$$

B , the population available to anglers = angling catch/exploitation rate

$$
\mathrm{B}=\mathrm{Catch} / \mathrm{Exp}
$$

## Therefore, $\mathbf{P A D}=0.16[($ Catch $/ E x p) / 0.84]$

By similar logic, PAD for small salmon was calculated as:

$$
\text { PAD }=0.14[(\text { Catch } / E x p) / 0.86]
$$

River harvest for small fish is the sum of fish lost to angling (including mortality associated with catch-and-release), broodstock collection and First Nations river removals. The mortality associated with catch-and-release of small salmon was assumed to be $6 \%$, the same as large salmon (Courtenay et al. 1991).

River harvest for large fish is the sum of fish lost to angling (Québec), mortality associated with catch and release (N.B., mainly), broodstock collection and First Nations river removals.

Spawning escapement was calculated as angling catch divided by angling exploitation rate minus river harvest. Angling exploitation rate is unknown for the Restigouche River, but Randall et al. (1990) argued that it is probably somewhere between 0.3 and 0.5 . Therefore, spawning escapements were calculated for these limits.

Returns were estimated as $7,447-11,652$ large (Tables 8,9 ) and 7,944-13,227 small (Tables $10,11)$ salmon. The ranges reflect the difference in the estimates when exploitation rate is set to 0.3 or 0.5 . Spawning escapement was calculated as 4,317-7,849 large and 3,691-8,235 small salmon (Figs. 3, 4).

## 3.4 - Pre-spawner surveys (snorkel)

### 3.4.1 - Abundance estimates

Snorkelling counts were carried out by MEF/LFN in the Matapedia and Patapedia rivers, and by DFO/DNRE in the Kedgwick, Little Main Restigouche and Upsalquitch rivers. Spot surveys only were carried out in the Main Restigouche River. The method used varied with river size and water clarity. For the most part, observations were made by divers, but when conditions allowed (clear water, weak current), some counts were conducted from canoes. Counts were made just before the spawning season when salmon were still concentrated in pools.

The MEF/LFN divers provided a single count for each tributary. In small tributaries such as the upper Patapedia and Causapscal rivers, one diver drifted downriver counting all salmon. In intermediate-size tributaries (e.g. the lower reaches of the Patapedia River), the team included a
diver and a canoeist. The canoe preceded the diver downriver, so as to funnel salmon towards the diver, who was responsible for counting. In large and deep rivers, such as the Matapedia River, two divers and a canoeist worked as a team, funnelling fish towards the second diver. As they drifted downriver, the first diver was responsible for counting fish passing between himself and the canoe. The second diver counted all other fish.

The DFO/DNRE divers provided replicate counts for most of the stretches surveyed so that observer variability could be examined. A team of two divers accompanied by a canoeist surveyed each section. Each diver drifted through each of the pools one or more times in order to obtain the best possible count of salmon in the time available. The total number of fish in the area counted was determined based on individual counts (where there was substantial difference in experience levels of the divers, the count of the more experienced diver was usually selected unless some other factor affected the relative quality of the two counts) or counts averaged over the two observers (where experience was reasonably similar). The methods by which the total count was obtained were determined after consultation with each team of divers and are documented on a case-by-case basis in Appendix 1. Similar results were obtained from a randomization routine which randomly selected counts from one or the other diver (Appendix 2).

Areas and dates covered by the MEF/LFN survey were:

- Kedgwick R.: N. Branch (Quigley Brook to Falaise Pool) - Oct. 8
- Patapedia R.: main stem (Forks to 2 Mile) - Oct. 17
- Matapedia R.: above Forks (including Humqui R.) - Oct. 11 \& 19, main stem (Forks to Matapedia) - Sept. 23-24

Areas and dates covered by the DFO/DNRE survey were:

- Kedgwick R.: N. Branch (Gin Creek to mouth), S. Branch (Union Brook to mouth), entire main stem - Oct. 7-9
- Little Main Restigouche R.: Boston Brook counting fence to mouth - Oct. 9
- Upsalquitch R.: Northwest Upsalquitch (10 Mile barrier fence to mouth), entire main stem. Spot-checked Southeast Upsalquitch (Shelter Pool to Southeast Falls) - Oct. 15-17
- Main Restigouche R.: Spot-checked (Junction to Down's Gulch - Oct. 8; mouth of Upsalquitch R. to Rafting Ground - Oct. 10)

A conservative estimate of abundance of spawners in 1997 is 4,677 large and 2,733 small salmon (4,501 large and 2,650 small, Table 12a; plus 176 large and 83 small, Main Restigouche $R$. spot-checks). This estimate is conservative because it excludes much of the Main Restigouche River, and, although fish were within a week of spawning at the time of the survey, migration into the tributaries may not have been completed. Counts were not adjusted to attempt to account for possible underestimation of fish by this method.

### 3.4.2 - Accuracy of abundance estimates

The accuracy of abundance estimates obtained from DFO/DNRE divers was examined using a tag observation experiment. Orange or yellow streamer tags, visible to divers on both sides
and above the salmon, were attached near the posterior edge of the dorsal fin of salmon seined during broodstock collections. Streamer-tagged salmon were released after fork length and sex were recorded. Fish were tagged at Junction (Sept. 3), Kedgwick Forks (Sept. 9), Cooksie (Sept. 29) and Bogan (Oct. 2) pools to estimate tag retention and observe fish movements (Appendix 3).

A smaller proportion of tags were reobserved during snorkelling than during the 1996 study. At best, $48 \%$ of large salmon tags and $28 \%$ of small salmon tags from the Kedgwick tagging (yellow tags) were reobserved approximately one month after tagging. Very few of the orange tags were reobserved. In 1996, observers of similar experience levels saw approximately $70 \%$ of the yellow-tagged fish but very few orange tags. The lower proportions observed this year may be the result of the longer time lag between tagging and snorkelling (approximately 1 month in 1997 vs. approximately two weeks in 1996). This might have resulted in higher tag loss or perhaps the fish had time to move into headwaters or smaller tributaries which we did not snorkel. This result highlights a research need for a controlled experiment to study tag loss.

Fish stayed in the tributaries in which they were tagged and the majority of the reobserved tagged fish had moved upriver. All Junction Pool tags reobserved were in the Little Main Restigouche River.

An experiment on tag loss rates was conducted at the Jacquet River salmon protection barrier. On October 17, 45 orange tags and 42 yellow tags were applied. The pool was snorkelled on October 23, and only 19 orange and 25 yellow tags were observed. A total of 171 fish were observed in the pool, although there were 282 in the pool according to the fence records. Tag retention could therefore be calculated in two different ways:
(1) Tag retention $=$ no. observed/no. applied. By this method, retention of orange tags was $42 \%$ and retention of yellow tags was $60 \%$.
(2) Tag retention could be corrected for unobserved fish, assuming the same rate of observation for tagged fish as for total fish in the pool. By this method, corrected retention was $69 \%$ for orange tags and $99 \%$ for yellow tags.

Tag retention during the first week is therefore probably in the range of: orange (42-69\%), yellow ( $60-99 \%$ ). Tag retention over longer time periods is not known; a later attempt to snorkel the pool failed due to poor visibility.

Observations during the 1996 and 1997 surveys of the Restigouche support an hypothesis of colour-dependent tag retention: the only tags reobserved in any numbers were the yellow ones. This finding is consistent with snorkeller observations that some of the orange tags retained on salmon are badly damaged and often all that is left is the base of the tag. The yellow tags observed were all intact. The difference in condition of the two tag types probably relates to the different response of salmon to colour. Anglers believe that the colour orange is attractive to salmon and often include this colour when designing salmon flies. It is likely that the behaviour of other salmon is responsible for the observed damage to the orange tags.

Any planned experiment to study loss of the streamer tags should take colour into account. Another factor which should be considered is whether the artificially high density of fish in the barrier pool increased the loss of tags in the experiment.

Recommendation: Continue to evaluate the performance of visual counts by divers. Repeat and expand the tagging experiment to determine whether similar proportions of tagged fish are observed annually and in different river stretches. Expand coverage of diver counts to the whole system. Conduct a controlled experiment to study tag loss rates over a period of one to four weeks. Examine the effects of colour and fish density on tag loss; a different tagging method of equal visibility but with less tag loss could be sought.

## 3.5 - Spawner surveys (canoe)

Spawner surveys were carried out by DNRE and DFO (Conservation \& Protection) personnel in autumn, as close as possible to the time of spawning when fish were observed on gravel bars. Fish were counted in New Brunswick and provincial boundary waters by observers standing in canoes while poling downstream. Areas inaccessible to canoes were walked. Counts provided for Québec waters have been collected as described in section 3.4 since 1992, but were carried out by MEF from canoes in previous years. DNRE collated the data from various sources and provided abundance estimates for each tributary. Redd counts or historical abundance relationships between parts of the system were used by DNRE to estimate spawner abundance in areas not sampled. Barrier fence counts were added to the totals for the Little Main Restigouche and Causapscal rivers. The area above the barrier fence on the Northwest Upsalquitch River was surveyed in 1997 so the barrier fence counts were not included in total counts. Canoe-based surveys were carried out in 1997 in the Upsalquitch, Little Main Restigouche and Main Restigouche rivers. The diver counts described in section 3.4 were used for other portions of the system.

The estimated abundance of spawners in the entire system in 1997 was 5,764 large and 2,280 small salmon (Table 12b).

## 3.6-Assessment results

|  | Large spawners |  | Small spawners |  |
| :--- | :--- | :--- | :--- | :--- |
|  | Estimate | \% of <br> requirement | Estimate | \% of <br> requirement |
| Conservation requirement | 12,200 |  | 2,600 |  |
| Diver spawner counts (partial count) | 4,677 | 38 | 2,733 | 105 |
| Canoe-based spawner counts | 5,764 | 47 | 2,280 | 88 |
| Angling exploitation estimate, | $4,317-$ | $35-64$ | $3,691-$ | $142-317$ |
| ER=0.5-0.3 | 7,849 |  | 8,235 |  |

All assessment methods concluded that large salmon spawning escapement was well below the conservation requirement. Visual assessment methods estimated large salmon abundance within the range bounded by the angling catch-based method, which was $35-64 \%$ of the conservation requirement. Given that the diver counts did not cover the entire system, were conducted before all spawners were distributed in the system, and probably did not observe all salmon in the stretches surveyed, it is likely that large salmon spawning escapement was underestimated at $38 \%$ of the requirement. Adding canoe-based counts ( 711 large, 282 small salmon) for the Main Restigouche River (not completely covered by the divers) to the diver counts for tributaries (4,501 large, 2,650 small salmon) yields an estimate of 5,212 large and 2,932 small salmon approximating $43 \%$ of the large salmon and $113 \%$ of the small salmon conservation requirement, somewhat lower than the estimate of large salmon escapement provided by the canoe-based counts. Spawning escapement of small salmon was estimated lower by the visual methods than by the angling exploitation rate methods, but only the canoe-based counts considered escapement to be less than the conservation requirement. It is likely that this was not an accurate evaluation of small salmon abundance. Small salmon are underestimated from canoes but there is less bias from diver counts (Locke 1997). According to the conservative (because of incomplete spatial coverage) diver counts, small salmon exceeded the conservation requirement.

Using a combination of the visual methods to estimate spawning escapement to be at least 5,200 large and 2,900 small salmon, returns were at least 7,300 large and 6,000 small salmon. Estimated returns by the angling catch-based method were 7,400-11,700 large and 7,900-13,200 small salmon (Tables 8-11). The visual estimate of returns is more conservative since it does not include an adjustment for losses to poaching and disease, which is incorporated in the angling catch-based method.

Returns and spawning escapement of both large and small salmon were mainly lower in 1997 than in 1996, but within the ranges observed in the 1990s (Tables 8-11).

## 3.7-Electrofishing

Juvenile salmon were electrofished by DFO at 15 standard sites during July, August and September (Fig. 1). Barrier nets were placed around the perimeter of the site and usually four sweeps of the area were completed. Abundances were calculated by the removal method (Zippin 1956). Densities of juveniles per unit area were determined using site areas measured at the time of sampling. Ninety-five percent confidence intervals of the mean densities were calculated after individual site counts were transformed to natural logarithms. Densities of salmon fry and parr have been estimated at these sites each year since 1972.

Densities of all juvenile age classes were high relative to the five-year mean. Mean densities of 71.3 age $0,13.9$ age 1 and 3.0 age 2 parr per $100 \mathrm{~m}^{2}$ had increased by $29 \%, 15 \%$ and $7 \%$, respectively, relative to their five-year means (Table 13, Fig. 5).

Thirteen additional sites were fished as "open" sites (i.e., timed stations without barrier nets) in 1997. To calibrate juvenile densities at open sites against the standard sites, a timed $10-$ minute sweep was made at the standard sites before they were fished by the usual method. Regression analysis then compared the catch per unit effort (CPUE) of the simulated open technique to the total density per $100 \mathrm{~m}^{2}$ of the standard technique. $\mathrm{R}^{2}$ values of 0.89 (age 0 ) and 0.87 (age 1 and 2 combined) were obtained (Fig. 6). In both regressions, the intercepts were not significant at $\mathrm{P}<0.05$ but slopes were significant at $\mathrm{P}=0.0001$.

Results from the "open" sites will be discussed under the tributary-specific assessments.

## 4 - Kedgwick River

## 4.1-Conservation requirements

The requirement for the Kedgwick River is: 6.89 million eggs, to be obtained from 933 large and 305 small salmon (Table 1).

## 4.2-Fishery data

Angling catch in the Kedgwick River in 1997 was 170 large and 295 small salmon (Table 14). Catches of both large and small salmon have been relatively low since about 1990 (Table 15, Fig. 7).

Angling harvest was five large and 267 small salmon (Table 14).
There was no First Nations harvest of salmon recorded on this river in 1997.

## 4.3-Adult abundance estimate

Salmon observed in Junction Pool during the snorkelling survey were divided into Little Main Restigouche River (75\%) and Kedgwick River ( $25 \%$ ) stocks based on subsequent observations of fish tagged in Junction Pool during the 1996 and 1997 surveys. This is a change from past practice in which Junction Pool fish were enumerated with the Kedgwick River stock.

Spawning escapement estimated by snorkellers was 492 large and 215 small salmon (Table 14). Egg production by these fish would have been 3.65 million eggs, or $53 \%$ of the conservation egg deposition.

Returns were estimated as 596 large and 484 small salmon (Table 14).

Compared to spawning escapement estimated by the same method in 1994-1996, both large and small salmon numbers were low in 1997 (Table 12a).

## 4.4 - Juvenile abundances

Mean juvenile densities at eight sites in the Kedgwick River were 90.3 age 0 and 22.1 age 1 and 2 parr per $100 \mathrm{~m}^{2}$ (Table 16, Fig. 8).

## 4.5-Broodstock and stocking

Charlo Salmonid Enhancement Centre (SEC) provided 100,000 eyed eggs and 40,000 feeding fry to MSRT (Management of Salmon in the Restigouche and Tributaries) for stocking in the Kedgwick River. Charlo SEC stocked 141,600 swim up fry and 185,118 age 0 parr directly to the river (Table 17).

A total of 69 large salmon broodstock ( 39 females, 30 males) were collected for the Charlo SEC at Kedgwick Forks Pool in 1997. These produced 400,069 eggs. Ten additional large salmon were collected, at the same time, as broodstock for an organization in Québec. In addition, 10 of the large salmon broodstock collected from Junction Pool (at the junction of the Kedgwick and Little Main Restigouche rivers) were considered to belong to Kedgwick stock as discussed in section 4.3.

## 4.6 - Prospects

Spawning escapement to the Kedgwick River in 1997 was poor, not much more than half the required egg deposition. Juvenile salmon abundances in this system appear to be quite high, therefore the prospects for future returns to this river may be reasonably good despite the poor escapement in 1997. A cautious approach to management of the river is recommended.

## 5 - Little Main Restigouche River

## 5.1-Conservation requirements

The conservation egg deposition is 5.38 million eggs, to be obtained from 984 large and 220 small salmon (Table 1).

## 5.2 - Fishery data

Angling catch in the Little Main Restigouche River in 1997 was 37 large and 130 small salmon (Table 14). Catches have been low in the 1990's (Table 15, Fig. 7). Data are not available prior to 1982 because catches in earlier years were pooled with Main Restigouche River catches.

Angling harvest was 0 large and 115 small salmon (Table 14).
There was no recorded First Nations harvest of salmon on this river.

## 5.3 - Boston Brook project

In 1997, a collaborative research program based at Boston Brook involved the Atlantic Salmon Federation and J.D. Irving, Ltd. The project consisted of a program intended to optimize salmon production, and included habitat analyses, adult salmon counts at a counting fence, juvenile densities determined by electrofishing, and stocking from a satellite rearing facility.

The counting fence operated from June 17 to October 17, with a period from July 23 to August 12 when counts were incomplete. In total, 132 large and 125 small salmon were counted. The majority ( $53 \%$ ) of the fish moved through the fence in October.

## 5.4 - Adult abundance estimate

As discussed in section 4.3, salmon enumerated in Junction Pool during the snorkelling survey were divided into Little Main Restigouche and Kedgwick stocks.

Spawning escapement was estimated as 846 large and 317 small salmon counted by snorkellers on October 9 (Table 14). Counts by canoeists the following week were 1,183 large and 340 small salmon (Table 12b).

From the more conservative snorkelling count, egg production would have been 4.65 million eggs, or $86 \%$ of the conservation requirement (Table 14). Returns to the river were 879 large and 433 small salmon.

## 5.5 - Juvenile abundances

Juvenile densities estimated by DFO at seven sites were 71.2 age 0 and 14.7 age 1 and 2 parr per $100 \mathrm{~m}^{2}$ (Table 16, Fig. 8). Mean values at four (main stem) sites sampled by the Irving/ASF project were 41.4 age 0 and 5.8 age 1 and 2 parr per $100 \mathrm{~m}^{2}$ (Whoriskey et al. 1998).

## 5.6-Broodstock and stocking

Broodstock collected from Junction Pool (at the junction of the Little Main Restigouche and Kedgwick rivers) are considered to belong to Little Main Restigouche and Kedgwick stocks as discussed in section 4.3.

In 1997, 100,000 eyed eggs and 20,000 feeding fry from the Little Main Restigouche stock were supplied to MSRT. An additional 72,550 feeding fry were supplied to other satellite rearing sites (Larrys Gulch, Camp Harmony, Watiqua II, Runnymede, Boston Brook). Charlo SEC stocked 201,500 swim up fry and 16,600 age 0 parr directly to the river (Table 17).

In total, 41 (31 Little Main Restigouche stock and 10 Kedgwick stock) large salmon broodstock ( 21 females, 20 males) were collected and 229,635 eggs were produced.

## 5.7 - Prospects

The prospects for future salmon returns to the Little Main Restigouche River appear quite good, given that the conservative estimate of egg production in 1997 was $86 \%$ of the conservation requirement, and that an estimate based on the canoe-based counts would exceed the conservation requirement. Juvenile densities are also high on this river.

## 6 - Patapedia River

## 6.1 - Conservation requirements

Conservation egg deposition for the entire Patapedia River, based on $2.4 \mathrm{eggs} / \mathrm{m}^{2}$ of accessible habitat, is 3.57 million eggs, to be obtained from 622 large and 131 small salmon (Table 1).

MEF's conservation requirement for the Québec and New Brunswick (main stem) portions of the Patapedia ( $93 \%$ of the total area) is 2.33 million eggs, based on 1.68 eggs $/ \mathrm{m}^{2}$.

## 6.2 - Fishery data

Angling catch in the Patapedia River in 1997 was 56 large and 73 small salmon (Table 14). Sixty percent of these fish were caught by Québec anglers. Catches have been relatively low in this system since about 1990 (Table 15, Fig. 7).

Angling harvest was 35 large and 73 small salmon (Table 14).
There was no First Nations catch of salmon recorded for the Patapedia River.

## 6.3-Adult abundance estimate

Spawning escapement estimated by snorkelling approximately 45 km of the 75 km accessible in the main stem of the Patapedia was 448 large and 150 small salmon (Table 14). The estimated deposition of 2.6 million eggs was $73 \%$ of the total requirement for the river at 2.4 $\mathrm{eggs} / \mathrm{m}^{2}$ and provides a conservative estimate of stock status given that only a portion of the main stem was snorkelled. Taking only the main stem into account $\left(1.287 \times 10^{6} \mathrm{~m}^{2}\right.$, which is $87 \%$ of the total habitat area), the estimated egg deposition was $84 \%$ of requirement.

Returns to the Patapedia River were 484 large and 223 small salmon.

## 6.4 - Prospects

The large salmon escapement for this river was the lowest since snorkelling counts began in 1994. However, large salmon escapement of each of the previous three years exceeded requirements for the main stem of the Patapedia River. No juvenile densities have been measured in recent years.

## 7 - Upsalquitch River

## 7.1 - Conservation requirements

Conservation egg deposition in the Upsalquitch River is estimated as 10.09 million eggs, to be obtained from 1,839 large and 970 small salmon (Table 1).

## 7.2 - Fishery data

Angling catch in the Upsalquitch was 236 large and 878 small salmon (Table 14). Small salmon catch was higher than the previous two years, although large salmon catch was declining over this time period (Table 15, Fig. 7). Angling catch of small salmon on this river is typically much higher than large salmon. Angling harvest in 1997 was 841 small salmon.

Eel River Bar First Nation reported 11 large and 26 small salmon caught (Table 14). Pabineau First Nation and the N.B. Aboriginal Peoples Council, which also could have fished this river, did not report any catches.

## 7.3 - Upsalquitch fish barrier

Returns to the barrier fence operated by DNRE at 10 Mile Pool on the Northwest Upsalquitch River (Fig. 1) were 1,027 small and 461 large salmon (Table 18). These returns represent a decrease of $5 \%$ relative to the 5 -year mean for small salmon, and a decrease of $36 \%$ for large salmon. Large salmon comprised $31 \%$ of the total run to the fence, compared to $39 \%$ on average in the past five years.

## 7.4 - Estimates of adult abundance

Snorkelling counts of the Northwest Upsalquitch River (below the counting fence) and Main Upsalquitch River, combined with fence counts, estimated 722 large and 1,217 small spawners in this system (Table 14). Egg production was 4.33 million eggs, only $43 \%$ of the conservation requirement for the whole system. Excluding the Southeast Upsalquitch system ( 0.927 $\times 10^{6} \mathrm{~m}^{2}$, which is $22 \%$ of the total habitat area), the conservative estimate of egg deposition was $55 \%$ of requirement. Spot-checks of the Southeast Upsalquitch River during the snorkelling counts found relatively few salmon (Appendix 1).

Returns to the system are estimated as 753 large and 2,086 small salmon (Table 14).

## 7.5 - Electrofishing

Juvenile abundances at 10 sites on the Upsalquitch system were 59.5 age 0 and 18.7 age 1 and 2 parr per $100 \mathrm{~m}^{2}$ (Table 16, Fig. 8).

## 7.6 - Broodstock and stocking

In 1997, 5,601 feeding fry were provided to the Boland Brook satellite site. In October, 15,635 age 0 parr were stocked directly to the Upsalquitch River (Table 17).

Only 6 large salmon broodstock ( 4 females, 2 males) were collected from the Upsalquitch River, for a production of 39,787 eggs.

## 7.7 - Prospects

Egg production in the Upsalquitch River in 1997 was less than $50 \%$ of the recommended conservation level. Large salmon escapement was reduced by $56 \%$ relative to the previous two years when snorkelling counts have been conducted in this system. Juvenile abundances at electrofishing sites are reasonably good, but a cautious approach to management of harvests from this river is recommended.

## 8 - Matapedia River

## 8.1-Conservation requirements

The Matapedia is the largest tributary of the Restigouche system (Table 1). Conservation requirements, based on $2.4 \mathrm{eggs} / \mathrm{m}^{2}$ of accessible habitat, are 16.35 million eggs, to be obtained from 2,395 large and 504 small salmon. Calculated at $1.68 \mathrm{eggs} / \mathrm{m}^{2}$, the conservation requirement used by MEF is 11.44 million eggs.

## 8.2 - Fishery data

Angling catch in 1997 was 719 large and 450 small salmon (Table 14). Unlike the other four major tributaries of the Restigouche system, the Matapedia River small salmon catch has shown a fairly steady increase since the early or mid-1980s, concurrent with a steady decrease in large salmon catch (Table 15, Fig. 7). However, catches of both large and small salmon were low in 1997. Angling catch reported here differs slightly from the angling harvest reported in MEF statistics because it includes 30 large salmon hooked and released during the September season extension (R. Firth, CGSMP, pers. comm.). Angling harvest was 689 large and 450 small salmon.

There was no recorded First Nations harvest of salmon on the Matapedia River.

## 8.3 - Causapscal fish barrier

Returns to Ministère de l'Environnement et de la Faune (MEF)'s barrier fence on the Causapscal River (a tributary of the Matapedia River; Fig. 1) were 2 small salmon and 229 large salmon (Table 18). Large salmon numbers decreased relative to the five-year mean by $38 \%$, similar to the proportional change in large salmon returns to the Upsalquitch barrier fence. Since small salmon are not retained well by the conduit fence, their proportional change is not a valid indicator of abundance at the Causapscal fence.

## 8.4 - Estimate of adult abundance

Snorkelling estimates of spawning escapement were 1,993 large and 751 small salmon (Table 14). Egg deposition of 13.78 million was $84 \%$ of the requirement based on $2.4 \mathrm{eggs} / \mathrm{m}^{2}$. This egg deposition represents $120 \%$ of the requirement based on $1.68 \mathrm{eggs} / \mathrm{m}^{2}$.

Returns to the river were estimated as 2,684 large and 1,201 small salmon.

## 8.5 - Prospects

Returns and spawning escapement were reduced in 1997 relative to previous years, and egg deposition did not achieve a level of $2.4 \mathrm{eggs} / \mathrm{m}^{2}$. The Matapedia River was the only tributary of the Restigouche system in which large salmon returns exceeded the conservation level for spawning. Reductions in spawning escapement in this tributary were less than in most of the other four. Prospects for future returns to this river appear to be good.

## 9 - Management Considerations

The biological differences in salmon (size, age, potential egg production) from the five major tributaries clearly demonstrate the inappropriateness of managing the Restigouche system as a single unit. Tributary-specific stock characteristics must be taken into account.

None of the five stocks achieved egg deposition at the level of $2.4 \mathrm{eggs} / \mathrm{m}^{2}$. Egg depositions of the Little Main Restigouche and Matapedia stocks were closest to the conservation level, being estimated as $84-86 \%$ of the conservation requirement. Kedgwick, Patapedia and Upsalquitch egg depositions were estimated at $43-73 \%$ of the requirement. The condition of the Patapedia stock may be better than is indicated by this estimate because only a portion of the main stem was snorkelled. Taking into account the area of the main stem only, the Patapedia stock was estimated to have produced $84 \%$ of its egg requirement. The low estimate for the Upsalquitch stock may also be conservative since very little of the Southeast Upsalquitch River was checked during the snorkelling surveys. Excluding the Southeast Upsalquitch system, the Upsalquitch stock was estimated to have produced $55 \%$ of its egg requirement.

Large salmon returns in excess of spawning escapement requirements occurred only in the Matapedia River. Small salmon returns to all the tributaries were in excess of spawning escapement requirements.

Juvenile densities in the Kedgwick, Little Main Restigouche and Upsalquitch rivers all appear to be reasonably good. There w

## 10 - Research Recommendations

1. Continue tributary-specific assessments of this system.
2. Continue to evaluate the performance of visual counts by divers. Repeat and expand the tagging experiment to determine whether similar proportions of tagged fish are observed annually and in different river stretches. Expand coverage of diver counts to the whole system. Conduct a controlled experiment to study tag loss rates over a period of one to four weeks. Examine the effects of colour and fish density on tag loss. Investigate using a different type of tag.
3. Reliable harvest data from all sources is required for this assessment, regardless of the assessment method selected. The shift in assessment method to diver-based spawner counts has reduced the reliance of the assessment on accurate harvest data, at least to the extent of independently determining spawning escapement. Harvest data is still required to calculate returns. Angling catch and harvest data for this system are considered to be among the most complete in the Maritimes. No harvest data were obtained from three of the five First Nation communities fishing this year; in particular, the catch of Listuguj First Nation probably represents a major component of the total harvest.
4. A conservation requirement for egg deposition in the Main Restigouche River should be developed. This would require collection of biological data for fish that spawn in the main stem, and habitat estimates, taking habitat quality into account.
5. Standardization of interagency approaches to egg deposition (eggs $/ \mathrm{m}^{2}$ ) requirements for conservation is strongly urged. The appropriateness of the $2.4 \mathrm{eggs} / \mathrm{m}^{2}$ requirement, currently used by DFO as a default in the absence of river-specific data, should be evaluated, perhaps using electrofishing above barrier fences to determine juvenile survival rates at egg depositions higher than the average for the system.

## 11 - Acknowledgements

We thank R. McBain, D. McBain, T. Miller, J. Peter-Paul, A. Narvie, A. Lavoie, M. Arsenault, J. McDonald, and K. Ross for their participation in electrofishing, habitat and/or snorkelling surveys. Broodstock and stocking information was obtained from P. Cameron at DFO's Charlo Salmonid Enhancement Centre. G. Blanchard, DFO, provided the information on First Nations fishing agreements. We are grateful to E. Deschenes for assistance with canoes and personnel during the snorkelling study. We thank the anglers, camp managers, and conservation
officers who provided angling catch data and assisted in tagging fish for the snorkelling study. We thank participants at the Science Workshop and Peer Review meetings for comments which improved the analyses and manuscript.

| P.Q. | 493 | 729 | 755 | 1001 | 711 | 870 | -31\% | -16\% |
| Total | 3123 | 1880 | 3479 | 2199 | - | - | - | - |

- Québec First Nation harvests (1994 to 1997) are 1989.93 means. Thus, previous five-year means were not calculated in this and subsequent tables that involve First Nations harvests.

| Table 4. Estimated angling catches of salmon in the Restigouche River, 1970 to 1997. Estimates of large salmon (1984 to 1997) and small salmon (1996 to 1997) include released fish in New Brunswick. Estimates of large salmon (1997) include released (September) fish in Quebec. New Brunswick catch-and-release data were estimates from angling lodge logbooks, crown reserve angler questionnaires and DFO fishery officers. Québec catch-and-release data were estimates from Matapedia/Patapedia River Management Corporation. |  |  |  |  |  |  |  |  |  |

Appendix 2. Comparison of diver counts summed over tributary on a case-by-case basis with counts generated using a randomization routine which randomly selects diver 1 or diver 2's count at each pool. Counts obtained from a single diver were added to the randomized data from two-diver teams to obtain total counts for each system. The proportion of the count obtained from non-randomized single-diver reports is indicated.

| River | Method | Large salmon count | Small salmon count |
| :---: | :---: | :---: | :---: |
| Kedgwick | Case-by-case $\%$ by single diver Randomization (median, $95 \%$ confidence limits) | $\begin{aligned} & 492 \\ & 54 \\ & 464(444-494) \end{aligned}$ | $\begin{aligned} & 215 \\ & 64 \\ & 205(195-215) \end{aligned}$ |
| Little Main Restigouche | Case-by-case \% by single diver <br> Randomization (median, $95 \%$ confidence limits) | $\begin{aligned} & 777 \\ & 0 \\ & 740(690-780) \end{aligned}$ | $\begin{aligned} & 208 \\ & 0 \\ & 240(200-260) \end{aligned}$ |
| Upsalquitch | Case-by-case $\%$ by single diver Randomization (median, $95 \%$ confidence limits) | $\begin{aligned} & 376 \\ & 10 \\ & 345(330-360) \end{aligned}$ | $\begin{aligned} & 254 \\ & 9 \\ & 235(220-250) \end{aligned}$ |

Appendix 3.
Summary of tags applied and observed, Restigouche salmon counts, 1997

| River | Tags applied |  |  |  |  | Tags observed by snorkellers |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | Date | Salmon | Grilse | Colour | Location(s) | Dates | Salmon | Grilse | Location(s) |
| Little Main | Sept. 3 | 35 | 11 | orange | Junction | Oct. 9 | 3 (9\%) | 0 (0\%) | Boston Brook Pool |
| Kedgwick | Sept. 9 | 27 | 72 | yellow | Forks | Oct. 7-9 | 13 (48\%) | 20 (28\%) | Quigley Bk. (N. Branch) \&Horne's Gulch (S. Branch) to 11 mile (Main Kedgwick) ( $82 \%$ at and above Forks; $97 \%$ at and above Frasers) |
| Upsalquitch | Sept. 29 | 12 | 4 | orange | Cooksie | Oct. 15-17 | 1 (8\%) | 1 (25\%) | Forks \& Island Pools |
| Upsalquitch | Oct. 2 | 1 | 0 | yellow | Bogan | Oct. 15-17 | 0 (0\%) | 0 (0\%) |  |

[^0]:    - River harvests (1984 to 1997) may include catch-and-release mortalities and broodstock and First Nations removals.
