#### Abstract

Egg deposition of Atlantic salmon in the Nepisiguit River in 1997 is believed to have been in the order of $50-60 \%$ of the requirement for conservation, similar to the situation of the past four years. The egg deposition requirement has not been met since 1988 .

The estimated egg deposition of Atlantic salmon in the Jacquet River was $52 \%$ of the conservation requirement. Conservation requirements for the Jacquet River were recalculated as 571 large and 347 small salmon. Spawning escapement of both large and small salmon was less than the conservation requirement, as was returns of large salmon.

\section*{Résumé}

On croit que la ponte du saumon atlantique dans la rivière Nepisiguit en 1997 correspondait à entre 50 et $60 \%$ de l'objectif de conservation, ce qui était le cas les quatre dernières années. L'objectif de ponte n'a pas été atteint depuis 1988.

La ponte estimative dans la rivière Jacquet correspondait à $52 \%$ de l'objectif de conservation. Un nouveau calcul des besoins de conservation les situe à 571 gros saumons et à 347 petits saumons. L'échappée de petits et de gros saumons était inférieure à l'objectif de conservation, tout comme les remontées de gros saumons.

## 1 - Introduction

Atlantic salmon occur naturally in the Nepisiguit (Fig. 1) and Jacquet (Fig. 2) rivers of northern New Brunswick. An active salmon stocking program has been carried out in the Nepisiguit River for the past two decades, initially to restore the population following a spill of mining waste and overfishing, and subsequently for enhancement purposes. In order to minimize losses of the existing wild population of the Jacquet River to poaching, the New Brunswick Department of Natural Resources and Energy has operated a salmon barrier fence since 1994.

This report documents the status of Atlantic salmon in the Nepisiguit and Jacquet rivers in 1997. For the Nepisiguit River, barrier fence counts, redd counts, estimates of angling catch, electrofishing surveys of juvenile abundance, and stocking data are summarized. For the Jacquet River, barrier fence counts and stocking data are presented. Electrofishing surveys of juvenile abundance in the Jacquet River in 1994-1996 are summarized. Conservation requirements for the Jacquet River are recalculated based on updated habitat measurements. In both rivers, egg depositions are estimated from salmon returns to the counting fences, removals and spawner abundances.

In the terminology utilised herein, salmon are subdivided into two size classes. Small salmon are adults less than 63 cm in fork length (1SW, one sea-winter salmon or grilse). Large salmon are adults greater than or equal to 63 cm in fork length (MSW or multi-sea-winter salmon).

## 2 - Nepisiguit River

## 2.1-Conservation requirement

The conservation egg deposition for Atlantic salmon in the Nepisiguit River is $9.535 \times 10^{6}$ eggs ( $\mathbf{1 6 2 6}$ large, $\mathbf{8 2 3}$ small salmon). This estimate was based on the following:

- accessible rearing habitat $=3.973 \times 10^{6} \mathrm{~m}^{2}$ (Anon. 1978)
- optimal egg deposition $=2.4 \mathrm{eggs} / \mathrm{m}^{2}$ (Elson 1975)
- average fecundity of females $=1,475 \mathrm{eggs} / \mathrm{kg}$ (Randall 1984)
- proportion of females in the large salmon population $=0.71$, and in the small salmon population $=0.17$ (Locke et al. 1994)
- mean weight of large salmon $=5.6 \mathrm{~kg}$, of small salmon $=1.4 \mathrm{~kg}$ (weights estimated at counting fence, R. Baker, pers. comm.).

The re-evaluation of rearing habitat recommended by Locke et al. (1997) could not be carried out in 1997, but should be attempted in 1998.

## 2.2 - Fisheries

### 2.2.1-Description of fisheries

Salmon fisheries in the Nepisiguit River include recreational angling and angling by members of Pabineau First Nation.

The recreational angling season was June 1 to October 15. Only hook-and-release fishing was permitted for large salmon, with a daily hook-and-release limit of four fish. Seasonal and daily bag limits for small salmon were eight and two fish, respectively. Anglers were required to stop fishing once the daily small salmon limit was reached.

The angling season for Pabineau First Nation, under an agreement with DFO, was June 1 to December 31. A quota of 400 small salmon was to be captured by angling only.

### 2.2.2 - First Nation fishery

The catch of First Nation anglers was estimated as 85 small salmon caught by 11 individuals (B. Paul Jr., Pabineau First Nation, personal communication). Approximately 75\% of this catch occurred after September 1.

### 2.2.3-Nepisiguit Salmon Association angling catch estimate

Angling catches estimated by the Nepisiguit Salmon Association (NSA) were 200 retained and 50 released small salmon, and 300 released large salmon (Table 1). Compared to the five-year mean of 633 small salmon and 300 large salmon, the 1997 angling catch of small salmon was down by $61 \%$ and large salmon catch was unchanged (Table 2, Fig. 3).

Fishing effort in 1997 ( 2200 rod-days) was the lowest estimated by NSA since 1984, and was $40 \%$ lower than the five-year mean of 3680 rod-days (Table 2). As in the previous three years (Locke et al. 1995; Locke and Mowbray 1996, 1997), most of the angling effort occurred in September ( 800 rod-days) and October ( 600 rod-days before the season closure on October 15) (Table 1).

Monthly catch per unit effort (CPUE) was highest in October at 0.34 fish/rod-day followed by September at 0.29 fish/rod-day (Table 1). CPUE for the full season was 0.25 fish/rod-day, the same as the five-year mean (Table 2).

### 2.2.4 - FISHSYS angling estimate

Angling catches estimated by the N.B. Dept. of Natural Resources and Energy FISHSYS angler survey (W. Hooper, pers. comm.) were 334 retained and 137 released small salmon, and 326 released large salmon (Table 2). This was the lowest small salmon catch estimated by FISHSYS
since 1980. Fishing effort was estimated as 5121 rod-days, more than double the estimate obtained by the NSA. Small salmon catch was also estimated considerably higher than the NSA value, but large salmon catch was similar by both methods. Catch per unit effort for the full season was 0.16 fish/rod-day, considerably lower than the NSA estimate but similar to FISHSYS estimates for 1994 and 1995 (no data were available in 1996).

### 2.2.5 - Angler logbooks

Angling logbooks completed by twelve members of the Nepisiguit Salmon Association indicated angling in 1997 (CPUE of 0.33 fish/rod-day) was poorer than in 1996 ( 0.43 fish/rod-day) or 1995 ( 0.35 fish/rod-day) but better than in 1994 ( 0.27 fish/rod-day) (Table 3 ).

As in the previous three years, most angling ( $89 \%$ of the total rod-days) by logbook anglers took place in the waters below the fence. In all three years, CPUE has been consistently higher below than above the fence. In 1997, CPUE below the fence was lower than any of the previous three years, but CPUE above the fence was average.

## 2:3 - Research data

### 2.3.1 - Juvenile stocking and broodstock collection

In 1996, the Charlo Salmonid Enhancement Centre (S.E.C.) stocked 150,000 fall fingerlings and 12,000 age 1 smolts (Table 4) into the Nepisiguit River and its tributaries below Grand Falls (Fig. 1). Fry were unmarked, but all smolts were adipose-clipped. This was the second year that age 1 smolts were stocked from Charlo S.E.C.

The Nepisiguit Salmon Association obtained 350,000 eyed eggs from Charlo S.E.C., for streamside incubation at Grand Falls. Survival rate in the incubation boxes was $92.4 \%$, producing 323,523 swim-up fry, of which 273,523 were stocked to the Nepisiguit River (Table 4). An additional 50,000 swim-up fry were stocked to the Tetagouche River above the falls. All fish were unmarked.

All broodstock used to produce eggs for this stocking were collected from the Nepisiguit River in 1996. In 1997, 103 large salmon ( $78 \%$ of the large salmon returns at the counting fence) were collected as broodstock. Two of these died after arrival at the hatchery.

### 2.3.2 - Counting fence

A salmon counting fence was operated by Pabineau First Nation in collaboration with Nepisiguit Salmon Association and DFO from June 14 to October 15 (Table 5). The fence was located in the Nepisiguit River, just above Gray's Ledge Pool.

Salmon captured at the fence during their upstream migration were counted, and all large and approximately $30 \%$ of small salmon were also measured, a scale sample was collected and fish were externally sexed if possible. Adipose fin clips (indicating hatchery origin) or numbered Carlin tags were noted. Salmon were released above the fence or retained as broodstock to be sent to Charlo Salmonid Enhancement Centre.

Very few salmon were recorded at the fence, compared to previous years (Table 6; Fig. 4). In total, 27 small salmon were counted at the fence. No small salmon were adipose fin-clipped (Table 6). In total, 132 large salmon were counted (including 1 fin-clipped).

Counts of salmon returning to the fence are believed to have been inaccurate, for two reasons. First, the fence was removed earlier than anticipated (due to budgetary constraints) and much of the late run entered the river following removal of the fence and during a 24 -hour period in mid-October when the fence was compromised due to leaf build-up and lifting of the fence. Second, gaps in the fence could have allowed salmon to pass through the fence without being counted. This observation is supported by angling catches and observations of small salmon upriver of the fence, early in the season before any small salmon had been counted at the fence (R. Baker, pers. comm.). Length frequencies of salmon recorded at the fence are also skewed toward larger sized individuals (Fig. 5).

In several previous stock assessments, returns to the fence were "adjusted" using angling catches and a regression equation (Locke et al. 1997). This was not done for the 1997 data because a large proportion of returns to the river are believed to have taken place after October 15, the end of the angling season on which the adjustments were based.

### 2.3.3 - Redd counts

Redd counts were conducted by the Nepisiguit Salmon Association both above and below the fence (Table 7). The total count was 2298 redds, very similar to the total of 2267 redds counted in 1996. The distribution of redds above and below the fence was also similar to that observed in 1996.

### 2.3.4 - Juvenile densities

Estimates of juvenile densities were obtained at 12 sites in the Nepisiguit River, 3 sites in Gordon Meadow Brook, and 6 sites in the Pabineau River electrofished by the Nepisiguit Salmon Association. Densities were estimated by the DeLury (1958) method, using removal from sites enclosed by barrier nets. Juvenile salmon were separated into age classes using fixed length categories (fry, $\leq 5.5 \mathrm{~cm}$; parr, $>5.5 \mathrm{~cm}$ ).

Mean density of fry in 1997 ( 30.1 fry $/ 100 \mathrm{~m}^{2}$ ) was the third highest recorded since 1982, and was exceeded only by values in 1991 and 1994 (Fig. 6). Mean density of parr ( 6.3 parr/100 $\mathrm{m}^{2}$ ) was the second lowest since 1990.

## 2.4 - Stock status

Based on the redd count data, spawning escapement of Atlantic salmon in the Nepisiguit River in 1997 was probably similar to levels calculated for recent years, approximately $50-60 \%$ of conservation requirement calculated for the entire accessible habitat. Spawning requirements have been exceeded in only two years (1987 and 1988) since 1982 (Table 8). Neither the conservation egg deposition or large salmon escapement have been met since 1988. Small salmon spawning escapement was exceeded in nine years, although not since 1993. Egg deposition has declined since 1989, but has remained at approximately $50-60 \%$ of the conservation level over the past four years.

## 2.5-Ecological considerations

### 2.5.1-Species interactions

Predation by piscivorous birds, primarily mergansers, on juvenile salmon is a major concern of some anglers on the Nepisiguit River. Merganser surveys carried out by the NSA and/or DNRE in July-September in 1994 through 1997 have counted similar numbers of mergansers in each year a maximum of about 1.7 mergansers/river km, with up to 48 birds on the Nepisiguit River below Grand Falls in 1997.

### 2.5.2 - Environmental conditions

Morning water temperature at the counting fence (sampled daily at approximately 0800 h ) rarely exceeded 20 C and never exceeded 25 C (Fig. 4).

Spot-checks of river pH by the NSA on September 2 and October 20 showed circumneutral readings: Nepisiguit River (7.04-7.81), and Pabineau River (7.00-7.51).

## 2.6-Management considerations

The recommended conservation level of spawning escapement was not achieved in 1997. Egg deposition is believed to have been approximately $50-60 \%$ of the conservation level.

## 3 - Jacquet River

## 3.1 - Conservation requirements

The conservation egg deposition that has been used for the Jacquet River is $\mathbf{2 . 7 2 4}$ million eggs, based on an estimated habitat area of 1.135 million $\mathrm{m}^{2}$. Based on this habitat area and updated biological data, Locke et al. (1997) recalculated the fish required to produce these eggs as 412 large and 250 small salmon.

Habitat surveys conducted by the N.B. D.N.R.E. in 1968-69 (Appendix 1) determined a habitat area of 1.574 million $\mathrm{m}^{2}$. Based on this revised habitat area, conservation requirements are increased by $39 \%$ to 3.778 million eggs to be obtained from 571 large and 347 small salmon.

## 3.2 - Fisheries

Unlike the Nepisiguit River, angling for kelts was permitted in the Jacquet River from April 15 to May 15. Angling regulations for bright fish in the Jacquet River were similar to those in the Nepisiguit River with the exception of a later season closure, October 30.

The New Brunswick Aboriginal Peoples Council received a communal license for salmon fishing in a number of rivers, including the Jacquet River, with a total allocation of 45 small salmon. These salmon were to be taken by angling only, from the waters of the Upsalquitch, Charlo, Benjamin and Jacquet rivers in August 1 through October 31, and from the waters of the Restigouche River from the confluence of the Restigouche and Matapedia rivers for a distance of approximately 10 km upstream in August 1 through September 15.

Pabineau First Nation also received a communal license for 10 small salmon to be taken by angling in the Jacquet River between June 3 and December 31.

As in 1996, no catch or harvest data for either the regular angling or the Native fisheries were available for 1997. Mean 1990-1995 angling catches were 19 small and 24 large kelts, and 67 small and 55 large bright salmon (Table 9). Fishing effort on bright salmon increased and CPUE decreased over this six-year period.

## 3.3 - Research data

### 3.3.1 - Juvenile stocking and broodstock collection

In 1997, 17,200 swim-up fry were stocked to the Jacquet River on June 17 and 18. Charlo Salmonid Enhancement Centre staff collected five large salmon (two males, three females) and one male grilse for broodstock.

### 3.3.2-Counting fence

In 1997, a barrier fence was operated by the municipality of Belledune in collaboration with DNRE. The fence was installed for the fourth year at Big Rock Pool just upriver of the Highway 11 bridge. The fence operated from June 27 to November 3. In total, 282 large and 371 small salmon returned to the fence (Fig. 7); this includes 104 large and 143 small salmon seined just below the fence by project personnel on October 17 and 23, and placed in the holding pool. This has been a standard procedure in all years of fence operation. There were no mortalities
recorded at the fence. Small salmon were released throughout the season to afford angling opportunities upriver.

As in previous years, the majority of fish ( $96 \%$ of large and $91 \%$ of small salmon) reached the fence after October 1 (Fig. 8).

### 3.3.3 - Juvenile abundance

Juvenile abundance in the Jacquet River was measured in 1994-1996 during electrofishing surveys of three to six sites by the DNRE. There were no electrofishing surveys in 1997.

Fry abundance in 1995 and parr abundance in 1996 were the highest of the three-year series (Fig. 9). Small salmon (grilse) from this cohort may be expected to return in 1998.

## 3.4 - Estimation of returns, removals and spawning escapement

Returns to the barrier fence were assumed to represent in-river returns. Mortalities at the fence were subtracted to obtain the number of salmon released above the fence. Removals of salmon upstream of the barrier fence were estimated as the mean angling mortality on bright fish in 1990-1995. Virtually all angling takes place above the fence (A. Madden, personal observation). Angling mortality of released large salmon was estimated as 3\% of the total catch.

## 3.5 - Stock status

Conservation spawning escapement was not achieved in 1997 (Table 19). Only $52 \%$ of the conservation egg deposition was met. Spawning escapement was estimated as 280 large ( $49 \%$ of requirement) and 304 small ( $88 \%$ of requirement) salmon.

Returns of large salmon (282 fish) did not exceed the conservation requirement (571 fish).

## 3.6-Management considerations

Atlantic salmon in the Jacquet River did not meet conservation requirements for the second year in a row. Large salmon spawning escapement was less than $50 \%$ of the requirement, and large salmon returns were less than the conservation requirement for spawning escapement.

## 4 - Research recommendations (Nepisiguit and Jacquet rivers)

1. Continue operation of the Nepisiguit River counting fence for assessment and broodstock collection. Early installation of the fence has been favoured in order to collect early-run broodstock. For the assessment program, it would be better to put the fence in later rather than earlier in order that the late October run of fish not be missed in the case of budget shortfalls.
2. Update the salmon habitat estimates in the Nepisiguit River, then reevaluate conservation requirements for total egg deposition.

## 5 - Acknowledgements

Much of the data on Atlantic salmon in the Nepisiguit River was collected by employees and volunteers of the Nepisiguit Salmon Association and Pabineau First Nation. We especially thank R. Baker, president of the NSA, and J. Grant and the staff of the counting fence. P. Cameron supplied DFO hatchery stocking data for both rivers. W. Hooper supplied DNRE electrofishing data for the Jacquet River. We thank the staff of the Jacquet River counting fence for their contributions to this report. R. Bernier assisted with data entry and analysis.

Table 8. Annual estimates of total returns and total spawners for large and small salmon in the Nepisiguit River. Spawner numbers in bold type exceeded the conservation spawning escapement of 1626 large salmon and 823 small salmon. Egg deposition is calculated from spawner estimates, assuming 5864.6 eggs/large spawner ( 8260 eggs/large female) and $351.05 \mathrm{eggs} /$ small spawner (2065 eggs/small female).

Table 10. Summary of Atlantic salmon stock assessment in the Jacquet River, 1994-1996. Egg deposition is calculated based on biological data collected at the counting fence in 1994-1996 (large salmon: 8229.8 eggs/female, $80.3 \%$ females in population; small salmon: 3735.3 eggs/female, $9.3 \%$ females in population).

|  | 1994 |  | 1995 |  | 1996 |  | 1997 |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | Large salmon | Small salmon | Large salmon | Small salmon | Large salmon | Small salmon | Large salmon | Small salmon |
| Returns (to fence) | 595 | 613 | 584 | 359 | 337 | 600 | 282 | 371 |
| Releases from fence (returns mortalities) | 594 | 603 | 582 | 354 | 335 | 595 | 282 | 371 |
| Angling mortalities | 3 | 33 | 0 | 61 | 2 | 67 | 2 | 67 |
| Spawning escapement | 591 | 570 | 582 | 293 | 333 | 528 | 280 | 304 |
| Egg deposition ( $\times 10^{6}$ ) | 3.9 | 0.2 | 3.8 | 0.1 | 2.2 | 0.2 | 1.9 | 0.1 |
| Total egg deposition (large+small salmon) ( $\mathrm{x} 10^{6}$ ) | 4.1 |  | 3.9 |  | 2.4 |  | 2.0 |  |
| $\%$ of conservation requirement met | 109\% |  | 103\% |  | 63\% |  | 52\% |  |

Figure 1. Map of the Nepisiguit River system, showing locations of the salmon counting fence at Sucker Pool in 1981-1991 and 1995-1997 and at Long Hole in 1992-1994.

Figure 2. Map of the Jacquet River, showing location of the barrier fence.

Figure 3. Angling catches, rod-days and catch per unit effort (CPUE) of bright Atlantic salmon on the Nepisiguit River, 1984-1997, according to estimates by the Nepisiguit Salmon Association.

Figure 4. Daily returns of small and large salmon, water levels, and temperatures at the Nepisiguit River counting fence, 1995-1997.

Fig. 5. Length frequency of Atlantic salmon returning to the Nepisiguit River counting fence in 1996 and 1997. Solid bars show number of males and hatched bars show number of females in each length category.

Figure 6. Mean juvenile salmon abundance at electrofishing sites on the Nepisiguit River (below Grand Falls), Pabineau River and Gordon Meadow Brook.

Fig. 7. Daily returns of small and large Atlantic salmon to the Jacquet River counting fence.

Fig. 8. Semi monthly returns of Atlantic salmon to the Jacquet River counting fence (19941997).

Figure 9. Mean juvenile salmon abundance at electrofishing sites on the Jacquet River.

Appendix 1. Estimate of salmon rearing habitat in the Jacquet River, obtained by stream surveys in 1968-1969 by New Brunswick Dept. of Natural Resources and Energy (W. Hooper, N.B.D.N.R.E., pers. comm.).
Section description
Habitat $\left(\mathrm{m}^{2}\right)$
Jacquet R. Falls to Rocky Brook confluence 19,796
Rocky Brook 0
Rocky Brook confluence to 3.2 km mark 33,846
3.2 km mark to Sheds 49,560
Sheds to Lower McNair 55,394
Lower McNair to Upper Crossing ( 4.8 km ) 23,463
Upper Crossing to Halfway 273,588
Halfway to Estuary 728,611
Lower South Jacquet tributaries (lower 8.5 miles) 146,772
Lower McNair Brook (lower 3.7 miles) 172,821
Big Hole Brook (lower 3.0 miles) 23,463
South Branch Jacquet (lower 5.0 miles) $\quad 46,671$
