Abstract

The seasonal distribution of the catch by gear type for this management unit was described. The catch was taken relatively evenly throughout the year. The total 4Vn catch between January and April was 18,231 t, 47% of which was taken by French vessels. The total catch in 4T between March and December was 39,039 t. The overall 1980 reported landings for this management unit (57,270 t) continued to increase after the historical low of 22,000 t recorded during 1977. A combined commercial catch rate index indicates minimum catch rates between 1974 to 1976 with a steady increase of approximately 150% to 1980. The research vessel survey data were re-analysed to produce log transformed population-at-age estimates as well as the routine stratified estimates. The total population estimate, by either method, has leveled off in 1980 subsequent to the strong increase since 1977. The survey indicates an uninterrupted series of good year-classes from 1973 to 1977. The catch numbers-at-age for 1979 and 1980 were generated using the appropriate commercial samples. The 4T coverage was particularly poor in 1980, the worst since 1975.

Estimates of population numbers from ages 3 to 9 at the end of 1980 were calculated using the survivor method. The mean fishing mortalities for ages 6 to 9 were 0.28 and 0.31 using respectively the transformed and untransformed survey data. VPA analyses were run using a mature F of 0.28 and an asymptotic partial recruitment vector (fully recruited at age 6). Partial recruitment at younger ages were adjusted using both the results of the survivor program (for ages 4 and 5) and a recruitment predictor (age 3). The VPA results were compared with both the combined commercial catch rate index and the research vessel population estimates. The correlations exceeded 0.94. The results indicate a reduction in partial recruitment at younger ages (3, 4 and 5) since the 1978 fishery. The year-classes from 1973 to 1977 inclusive have been exceptional, with that for 1977 almost double any year-class prior to 1973. The 5+ biomass is estimated to have climbed

to above 250,000 t. The 1982 projected yield at $F_{0.1}$ (0.2), assuming a catch of 53,000 t in 1981, is 65,000 t.

Résumé

La distribution saisonnière des prises par type d'engin dans cette unité de gestion montre une répartition relativement uniforme tout au long de l'année. Les prises totales dans la division 4Vn pour la période de janvier à avril ont atteint 18 231 t dont 47% ont été rapportées par la flotte française. Les prises totales dans la division 4T pour la période de mars à décembre furent de 39 039 t. Les débarquements totaux enregistrés en 1980 pour l'ensemble de l'unité de gestion (57 270 t) continuèrent à augmenter depuis le creux historique de 1977. L'indice combiné des taux de capture par la flotte commerciale indique un minimum entre 1974 et 1976 suivi d'une augmentation régulière jusqu'en 1980. Les données des relevés par les navires de recherche ont été analysées de nouveau pour donner des estimations de population par âge transformées sous forme logarithmique, ainsi que des estimations stratifiées routinières. L'estimation de population totale, obtenue par l'une ou l'autre méthode, a atteint un plateau en 1980 après la forte augmentation observée depuis 1977. Les relevés montrent une série ininterrompue d'importantes classes d'âge de 1973 à 1977. Des échantillons commerciaux appropriés ont permis de calculer les nombres par âge capturés en 1979 et 1980. La échantillonnage scientifique de 4T a été particulièrement pauvre en 1980, le pire depuis 1975.

On a fait appel à la méthode des survivants pour estimer les nombres de sujets d'âges 3 à 9 dans la population à la fin de 1980. Les mortalités moyennes par la pêche aux âges 6 à 9 étaient de 0,28 et 0,31, selon qu'on utilise respectivement les données transformées et non transformées des relevés. Des analyses de population virtuelle (APV) ont été effectuées avec un F d'âges pleinement recrutés de 0,28 et un vecteur de recrutement partiel asymptotique (plein recrutement à l'âge 6). Le recrutement partiel des âges plus jeunes a été ajusté en utilisant à la fois les résultats du programme SURVIVOR (pour les âges 4 et 5) et un indice de recrutement (âge 3). Les résultats de l'APV ont été comparés avec l'indice combiné des taux de capture commerciaux et les estimations de populations découlant des relevés par navire de recherche. Les indices de corrélations dépassent 0,94. Les résultats indiquent que le recrutement partiel des jeunes âges (3, 4 et 5) a diminué depuis 1978. Les classes d'âge de 1973 à 1977 ont été exceptionnelles, celle de 1977 étant presque le double de toute autre née avant 1973. On estime que la biomasse d'âge 5+ a bondi à plus de 250 000 t. Le rendement prévu pour 1982 avec un $F_{0.1} = 0.2$, à supposer des prises de 53 000 t en 1981, est de 65 000 t.

Catch Description

The catch was taken relatively evenly throughout the year, both within 4Vn during overwintering and on the Magdalen Shallows (4T) during the spring to autumn months (Fig. 1a).

The total catch in 4Vn between January and April was 18,231 t, the highest since 1975 (Fig. 2). The French vessels took 47%, with essentially all the remainder being taken by the larger Canadian otter trawls (tonnage classes 4 and 5). The total catch in 4T between March and December was 39,039 t, a slight decline in relation to 1979 but higher than any other year since 1973 (Fig. 2). The smaller otter trawls and Danish seines (tonnage classes 2 and 3) were the most important gear types in the 4T fishery but gillnets and hand and longlines accounted for approximately 20% of the catch (Fig. 1b). The overall 1980 reported landings for this management unit (57,270 t) continued to rise as the component stock(s) rebuild (Table 2, Fig. 2b). The TAC for 1980 was 54,000 t and this appears to have been exceeded by about 3,000 t. However, these landings statistics for 1980 are still preliminary particularly those for Quebec. The catches by gear-type for 1980 are shown in Table 1 (a,b,c), and the total annual catch since 1965 in Table 2.

Catch Per Unit Effort

The commercial CPUE indices that have been used in recent assessments were updated. The 4Vn indices calculated for Canadian otter trawls (tonnage classes 4 and 5) were high in 1980 but not as high as the somewhat anomalous 1978 values (Table 3a). Both indices for the Danish seiners, tonnage classes 2 and 3, increased to respectively 0.40 and 0.61 t/hour (Table 3b). The latter value is the highest in the time series. The otter trawl (tonnage class 3) CPUE was also high, but was a slight decrease from 1979 (Table 3a).

The trends since 1967 for the five commercial CPUE indices are shown in Figure 3. Although there is considerable year-to-year variability for any one series, the overall trend of increasing catch rates since 1978 is evident (with the exception of tonnage class 4 otter trawls in the winter fishery). The May to July indices within 4T were combined by taking an unweighted average of the three indices (Table 3c). Missing values were filled by averaging the nearest values. The combined index indicates minimum catch rates between 1974 to 1976 with a steady increase of approximately 150% to 1980.

The research vessel survey data was re-analysed to produce the routine stratified population-at-age estimates and log transformed estimates. The results are shown in Tables 4a and b. The total RV population abundance, by either method, has leveled off in 1980 subsequent to the strong increase since 1977. The 1977 year-class-at-age 3 is again by far the strongest in the time series, as was previously indicated in the 1979 survey. The Z values indicate some "availability" changes in the survey, being unrealistically low during

1978-79. The year-class strength indices (from 1970 to 1978) from the surveys are shown in Table 4c.

The survey estimates indicate an uninterrupted series of good year-classes from 1973 to 1977. The 1978 year-class (from the age 1+2 indices only) appears to be at best of moderate strength (ranking 4th or 9th in the respective series).

There is a good correspondence between the research vessel indices and the May to July commercial CPUE indices, with an r value as high as 0.99 between the combined index and the 4+ RV numbers. The winter fishery indices do not correlate well with either the summer CPUE indices or the RV population numbers. The trends since 1971 in the combined CPUE index and 4+ numbers (ln transformed) are shown in Figure 4.

Generation of Numbers-at-age in the Catch

The extent of the sampling of commercial landings since 1971 is summarized in Table 5. The coverage of the Canadian winter fishery (the large otter trawls) is relatively good, for example 17 samples representing less than 10,000 t in 1980. The catch by other gear components however is much less satisfactory. For example there is only a single sample representing the otter trawl catches in 4T between September and December, when a significant portion of the catch was taken. The 4T coverage was particularly bad in 1980, the worst since 1975.

The numbers-at-age for 1979 were re-generated. The new results indicate respectively an 86% and 10% increase in the age 4 and 5 fish in the catch relative to the previous assessment. The 1980 catches-at-age were generated on a quarterly basis by gear-type where possible. When not possible gear-types within a quarter were combined. The catch matrix from 1950 to 1980 is shown in Table 6. The 1950 to 1977 numbers were taken from Lett (1978) and the 1978 numbers from Gray (1979). Eighty-seven percent of the 1980 catch comprised the 1973 to 1975 year-classes. Thus if the sampling is adequate the strong 1976 and 1977 year-classes (as indicated by the RV survey) are not being selected for by the overall fishery.

Survivor

Estimates of the population numbers, from age 3 to 9, were derived using both the routine RV population estimates (Table 4a) and the log transformed estimates in the "survivor" program (Rivard 1980). The results are summarized in Tables 7a and b. The calibration block excluded the 1980 and the age 9 vectors. The coefficients of variation were relatively low using both RV survey matrices. The major difference between the two survivor runs is the relative strength of the 1975 year-class, 110 million using the untransformed data and 80 million using the transformed. There were only two outliers in the

residuals in each of the runs. The mean fishing mortalities for ages 6 to 9 were respectively 0.28 and 0.31 for the "transformed" and "untransformed" cases. These values compare favorably with the 1979-80 Z estimates shown in Tables 4a, b.

VPA Input Parameters

The initial partial recruitment vector (Table 8) was calculated from the fishing mortalities-at-age generated from survivor (i.e F at age 3, 4 and 5 divided by average of F's for ages 6 to 9). This assumes an asymptotic PR vector. The Fs for older ages were estimated by iteration using the average F each year of ages 6 to 12. The fully recruited F for 1980 was that estimated from the "survivor" run using the transformed RV survey population estimates. Natural mortality was 0.2. The weights-at-age for 1980 are shown in Table 8. The time series of weights-at-age for the winter fishery from 1950 to 1980 are shown in Table 9. The values from 1950 to 1977 were taken from Lett (1978), for 1978 from Gray (1979) and for 1979 and 1980 from this year's catch-at-age analysis.

VPA Results

The results of the VPA run using the above input parameters are shown in Tables 10a, b, and c. The VPA 4+ populations numbers in relation to the log transformed and untransformed RV population estimates are shown in Fig. 5. There is the suggestion of curvilinearity in the relationships, and the 1978 VPA population estimate is high in relation to the survey estimates. The relationship between 5+ VPA and the log transformed RV 5+ numbers looks linear, but again the VPA 1978 5+ estimates is relatively high (Fig. 6). The correlations for all four comparisons exceed 0.94. Fishable biomass (partial recruitment x mid-year population biomass) is related to the combined May to July CPUE index in Figure 7. There is not a suggestion of curvilinearity in this case. The VPA year-class strengths from 1970 to 1976 are compared to the two age 1+2+3 RV survey recruitment indices in Figure 8. There is a considerably tighter relationship using the log transformed index. The GM regressions are:

$$Y = 9814 + 2.20 X \quad r = 0.88 \text{ (untransformed survey)}$$

$$Y = -16,692 + 9.96 X \quad r = 0.96 \text{ (transformed survey)}$$

The predicted sizes of the 1977 year-class are respectively 254 and 264 million. The other index (RV age 1+2), which permits prediction of the 1978 year-class, was also considered. The relationships between these RV indices and VPA year-class strengths (Fig. 9) were weaker.

The GM regressions are:

$$Y = 16.84 + 0.00748 X, r = 0.80 \text{ (untransformed survey)}$$

$$Y = 24.67 + 0.0239 X, r = 0.69 \text{ (transformed survey)}$$

where X is VPA estimate of year-class strength at age 3 ($\times 10^{-3}$) and Y is the appropriate RV index ($\times 10^{-1}$). The predictions for the 1977 and 1978 year-classes in millions are:

	<u>1977</u>	<u>1978</u>
Regression 1.	363	89
Regression 2.	201	127

The predicted value for the 1977 year-class from the log transformed RV age 1+2+3 indice regression (264×10^6) was chosen. This results in a reduction of the partial recruitment at age 3 from 0.01 to 0.0036. The suggested changes in partial recruitment over the past three assessments are:

Age	Gray (1979)	Beacham (1980)	Survivor	This VPA
3	0.02	0.005	0.01	0.004
4	0.40	0.07	0.08	0.08
5	0.75	0.80	0.54	0.54
6+	1	1	1	1

The year-class strengths from 1947 to 1978 as well as the 5+ population biomasses from 1950 to 1980 are shown in Figure 10. This assessment indicates that the year-classes from 1973 to 1977 inclusive have been exceptional, with that for 1977 almost double any year-class prior to 1973. The 5+ biomass is estimated to have climbed to above, 250,000 t in 1979, reaching the levels estimated in the early 60's but still considerably below the peak values estimated for the mid 50's.

Yield Per Recruit

A Thompson-Bell yield per recruit analysis was carried out using both the present weight-at-age and PR conditions as well as more "average" conditions. The following input values were considered:

<u>Age</u>	<u>RUN 1</u>		<u>RUN 2</u>		<u>RUN 3</u>	
	<u>Wt</u> ¹	<u>PR</u> ³	<u>Wt</u> ²	<u>PR</u> ³	<u>Wt</u> ²	<u>Pr</u> ⁴
3	0.54	0.004	0.25	0.004	0.025	0.02
4	0.69	0.08	0.72	0.08	0.72	0.40
5	0.90	0.54	0.98	0.54	0.98	0.75
6	1.20	1	1.31	1	1.31	1
7	1.51	1	1.71	1	1.71	1
8	2.65	1	2.21	1	2.21	1
9	3.13	1	2.64	1	2.64	1
10	4.15	1	3.24	1	3.24	1
11	8.27	1	3.72	1	3.72	1
12	6.40	1	4.41	1	4.41	1
13	11.11	1	6.25	1	6.25	1
14	5.52	1	6.52	1	6.52	1
15	10.10	1	7.23	1	7.23	1

$$F_{0.1} = 0.177$$

$$F_{0.1} = 0.215$$

$$F_{0.1} = 0.201$$

1 1980 mean weights-at-age for the overall fishery

2 1950 to 1980 mean weights-at-age for the winter fishery (4Vn)

3 Final partial recruitments in this assessment

4 Partial recruitment used by Gray (1979) representing a period of low adult biomass.

Run 1 represents present conditions to the degree that the present analysis is correct. Runs 2 and 3 represent long-term average weight-at-age distributions and two extremes in the partial recruitment pattern. The 1979 and 1980 assessments used $F_{0.1}$ values of respectively 0.200 and 0.195.

Projections

A three year projection was run. The input parameters were:

- (i) the 1977 year-class set at 175×10^6 fish (the highest on record but lower than the VPA estimate)
- (ii) weights-at-age as estimated for the 1980 overall fishery
- (iii) partial recruitment estimated for the 1980 fishery
- (iv) the 1978 and 1979 year-classes equal to the geometric mean of VPA estimated 1964 to 1976 year-class strengths (78.5 million)

Assuming the 1981 TAC of 53,000 t is taken, the catch at $F_{0.1} = 0.20$ in 1982 is calculated to be 65,000 t (Table 11).

Table 11. Catch projections through 1982 under assumptions described in text.

Catch Biomass

	1980	1981	1982
3	179	31	31
4	1758	1416	638
5	12938	8633	9638
6	16055	15686	15041
7	14404	9246	13266
8	4370	11569	10906
9	2529	2362	9184
10	1660	1534	2105
11	1993	1514	2055
12	237	706	788
13	322	188	824
14	50	73	63
15	202	41	90
	56697	53000	64628

Fishing Mortality

	1980	1981	1982
3	0.002	0.001	0.001
4	0.022	0.016	0.016
5	0.151	0.108	0.108
6	0.280	0.200	0.200
7	0.280	0.200	0.200
8	0.280	0.200	0.200
9	0.280	0.200	0.200
10	0.280	0.200	0.200
11	0.280	0.200	0.200
12	0.281	0.200	0.200
13	0.281	0.200	0.200
14	0.284	0.200	0.200
15	0.280	0.200	0.200

FIG. 1(a)

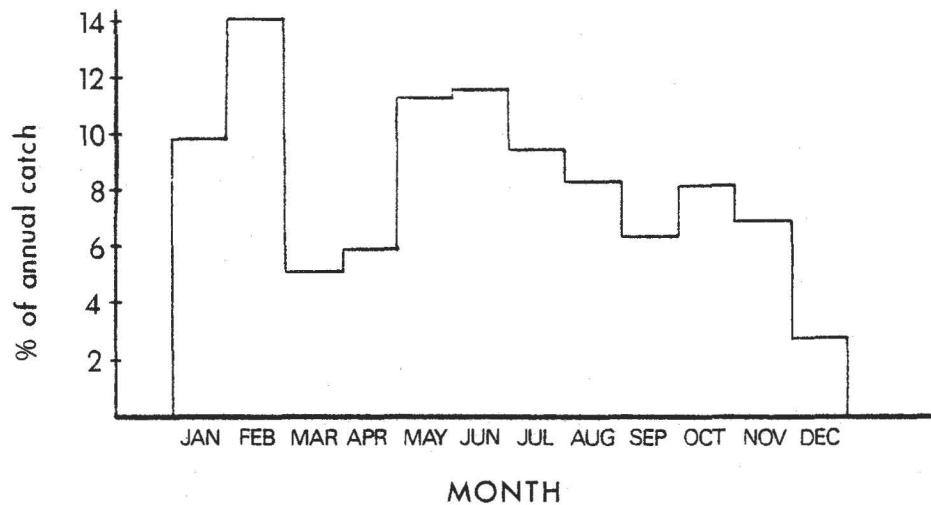

FIG. 1(b)

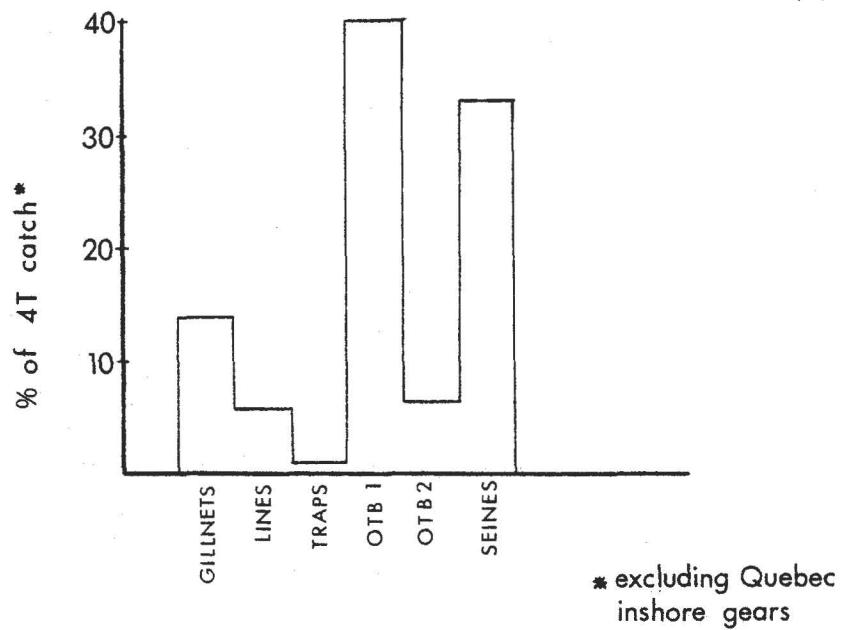

Figure 1a. Monthly distribution of catch (%) of 4TVn cod.

1b. Relative contribution (%) of various gear types to the landings of cod in 4T.

FIG. 2 (a)

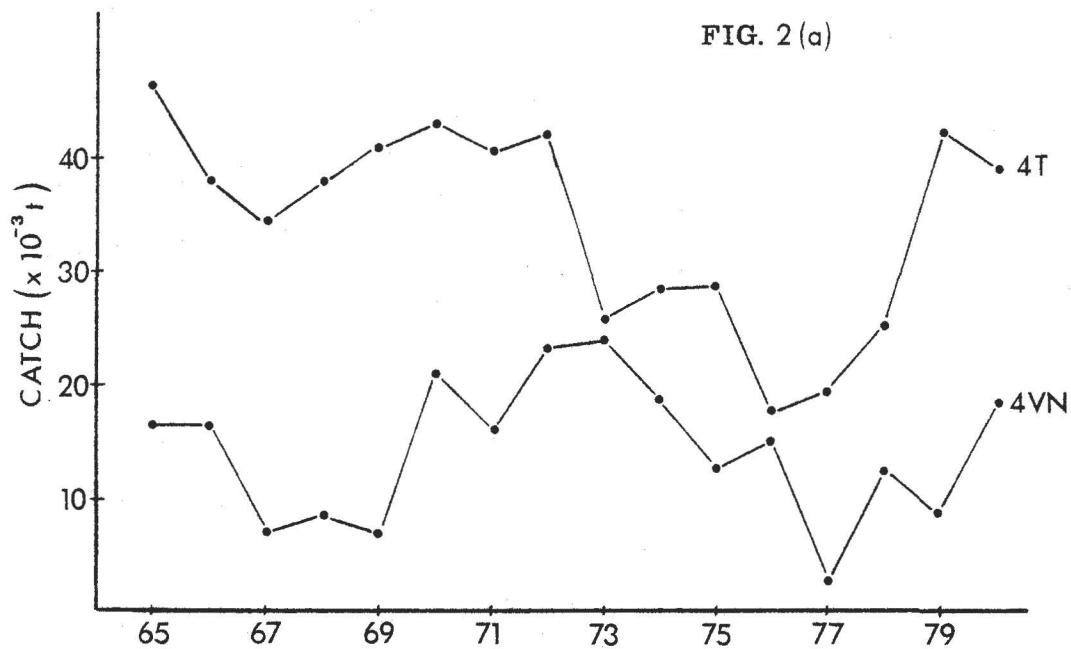

FIG. 2(b)

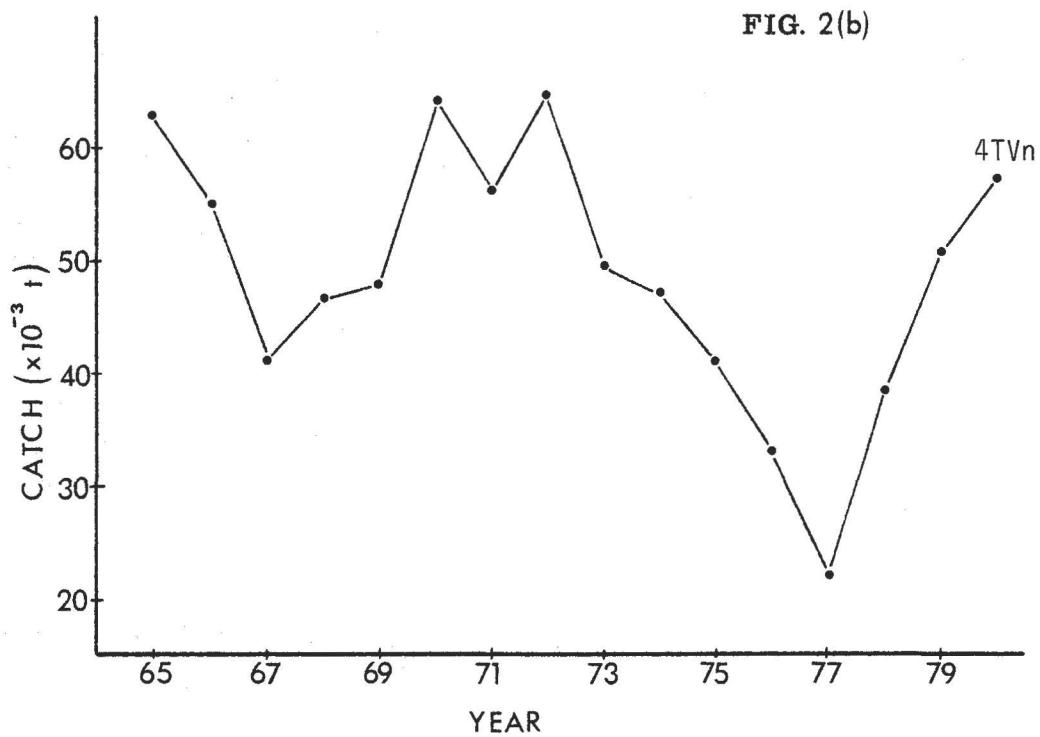

Figure 2. Trends in landings of 4TVn cod from 1965 to 1980.

FIG. 3 a

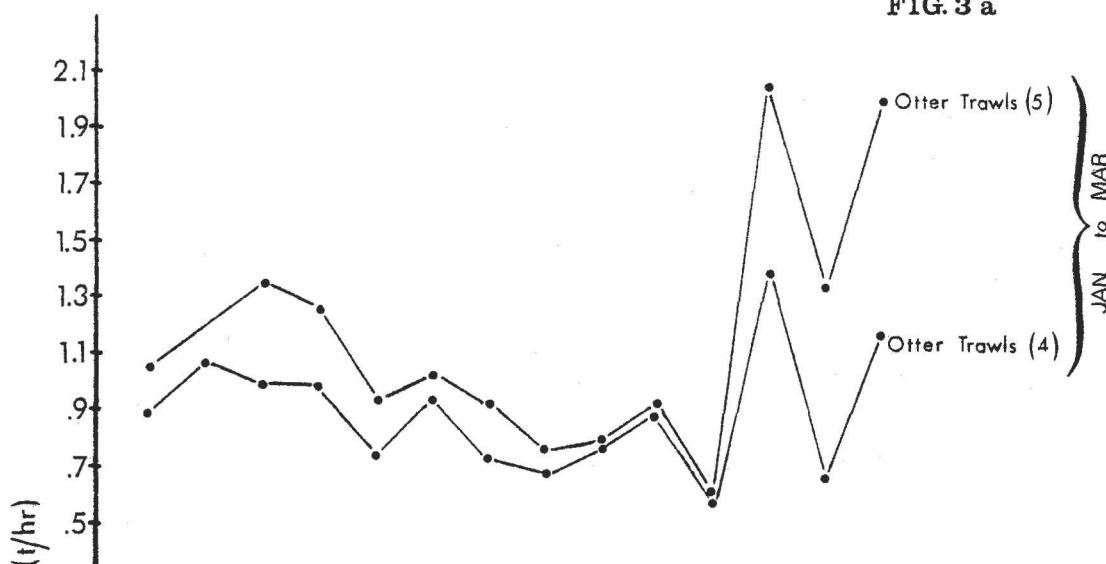

FIG. 3 b

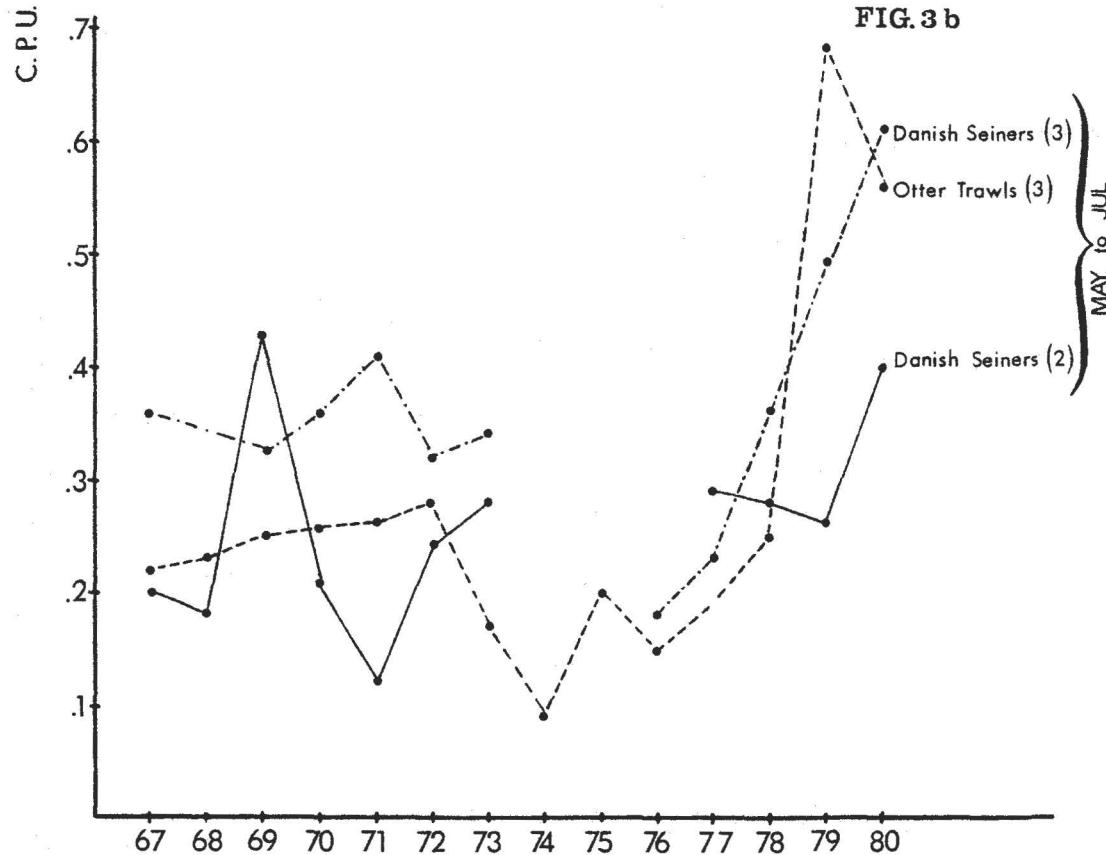

Figure 3. Trends in catch per unit of effort for several gear types participating in the 4TVn cod fishery (1967-1980).

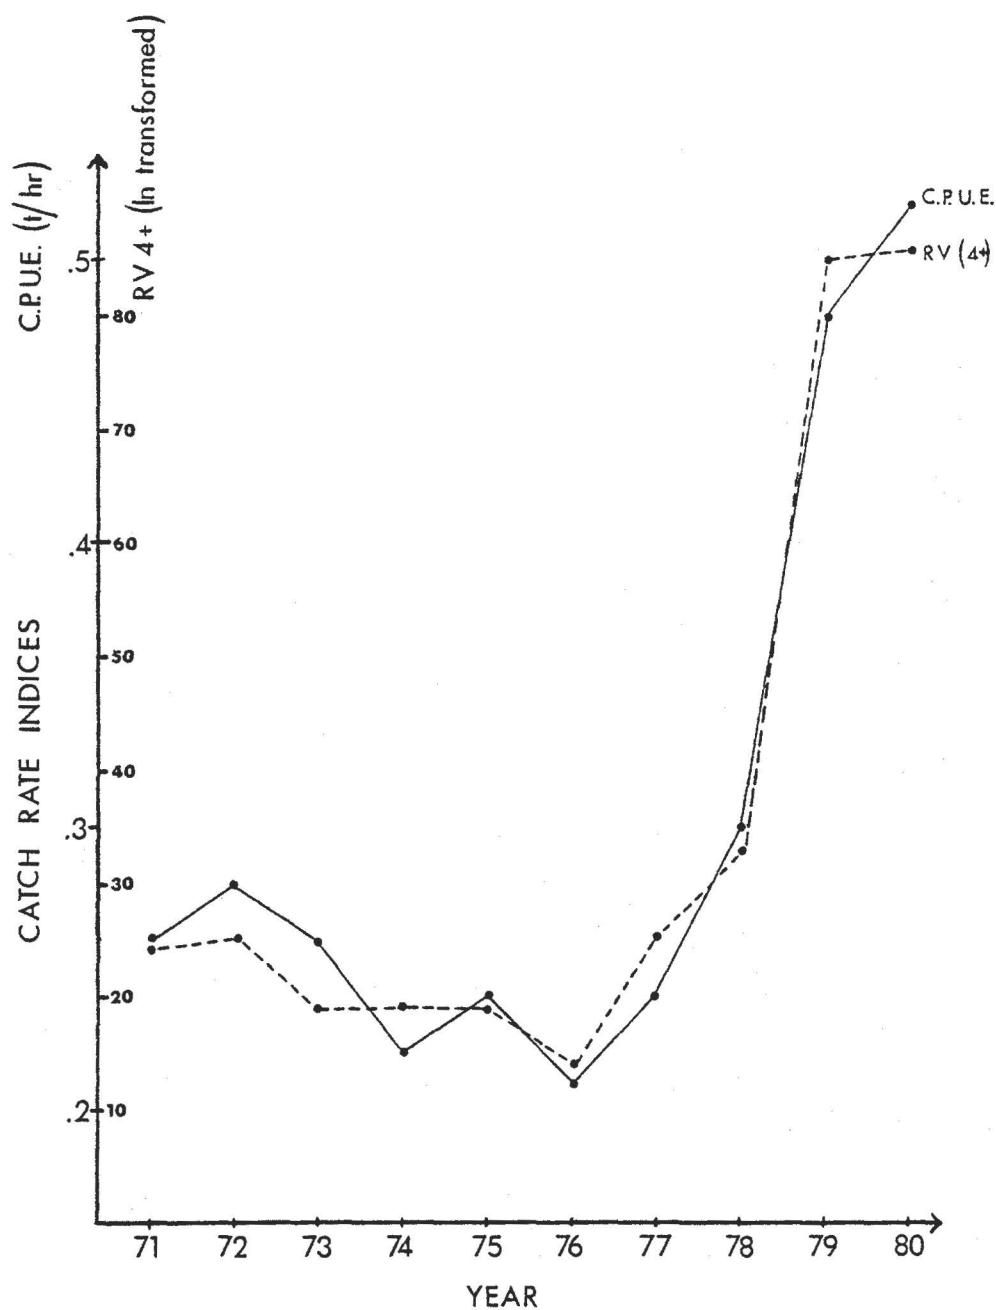

Figure 4. Trends in a combined CPUE index for the 4TVn cod fishery and 4+ numbers of cod estimated from the research vessel survey (1971 to 1980).

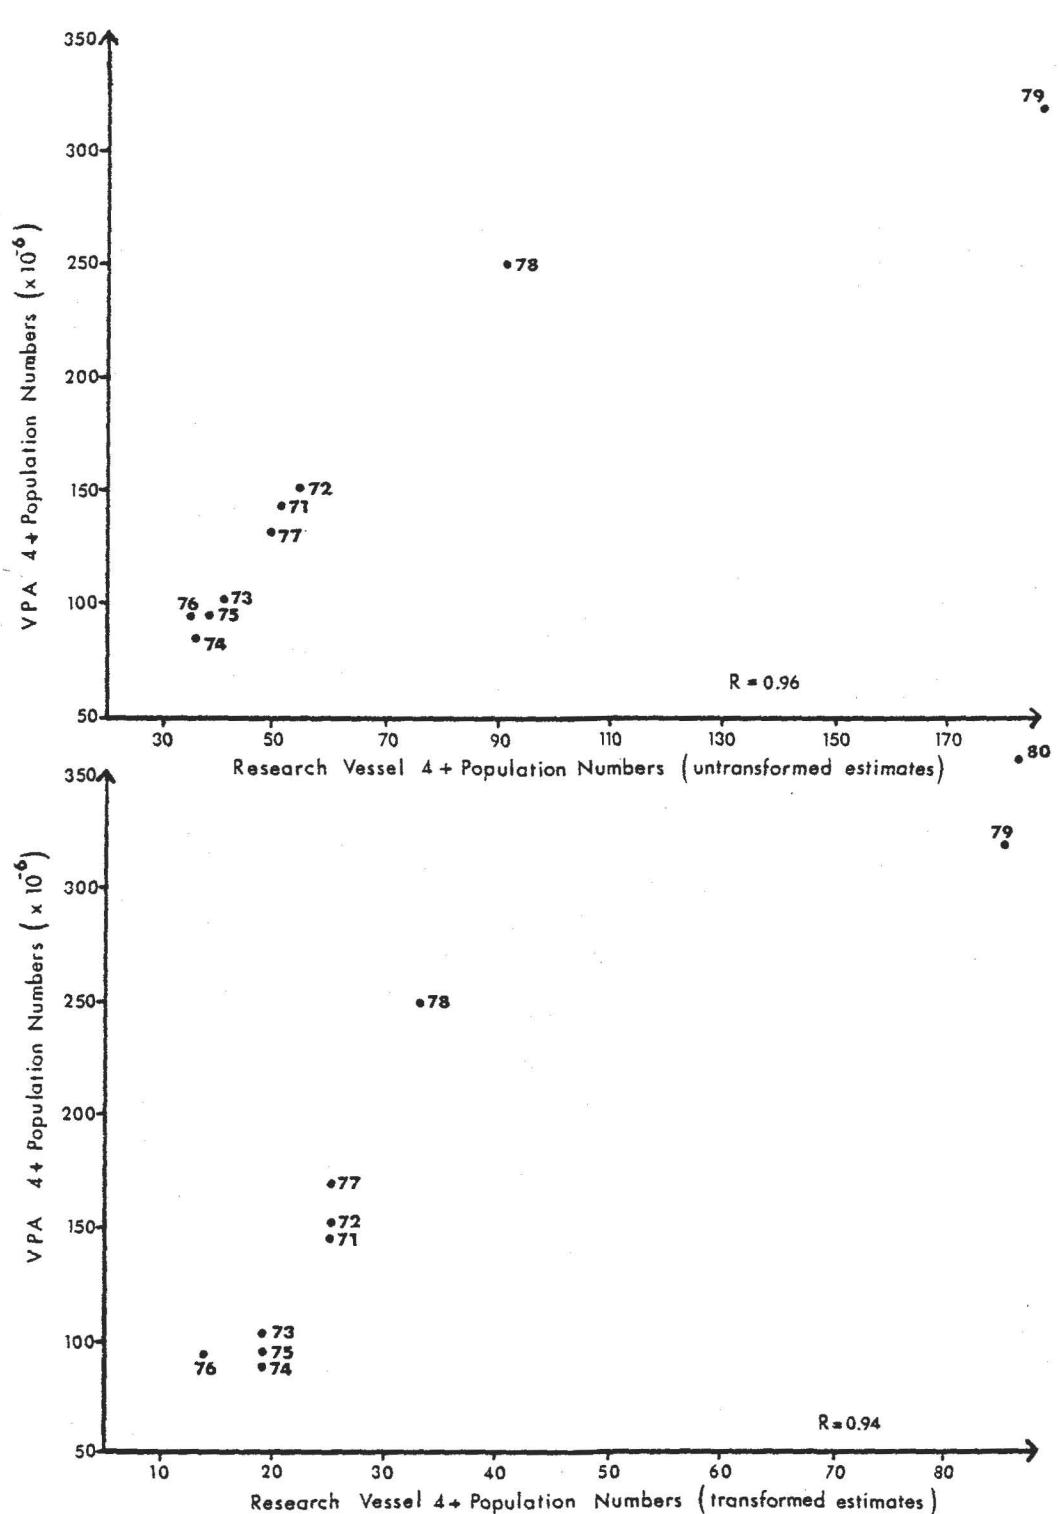

Figure 5. Relationship between VPA 4+ numbers and research vessel 4+ numbers.

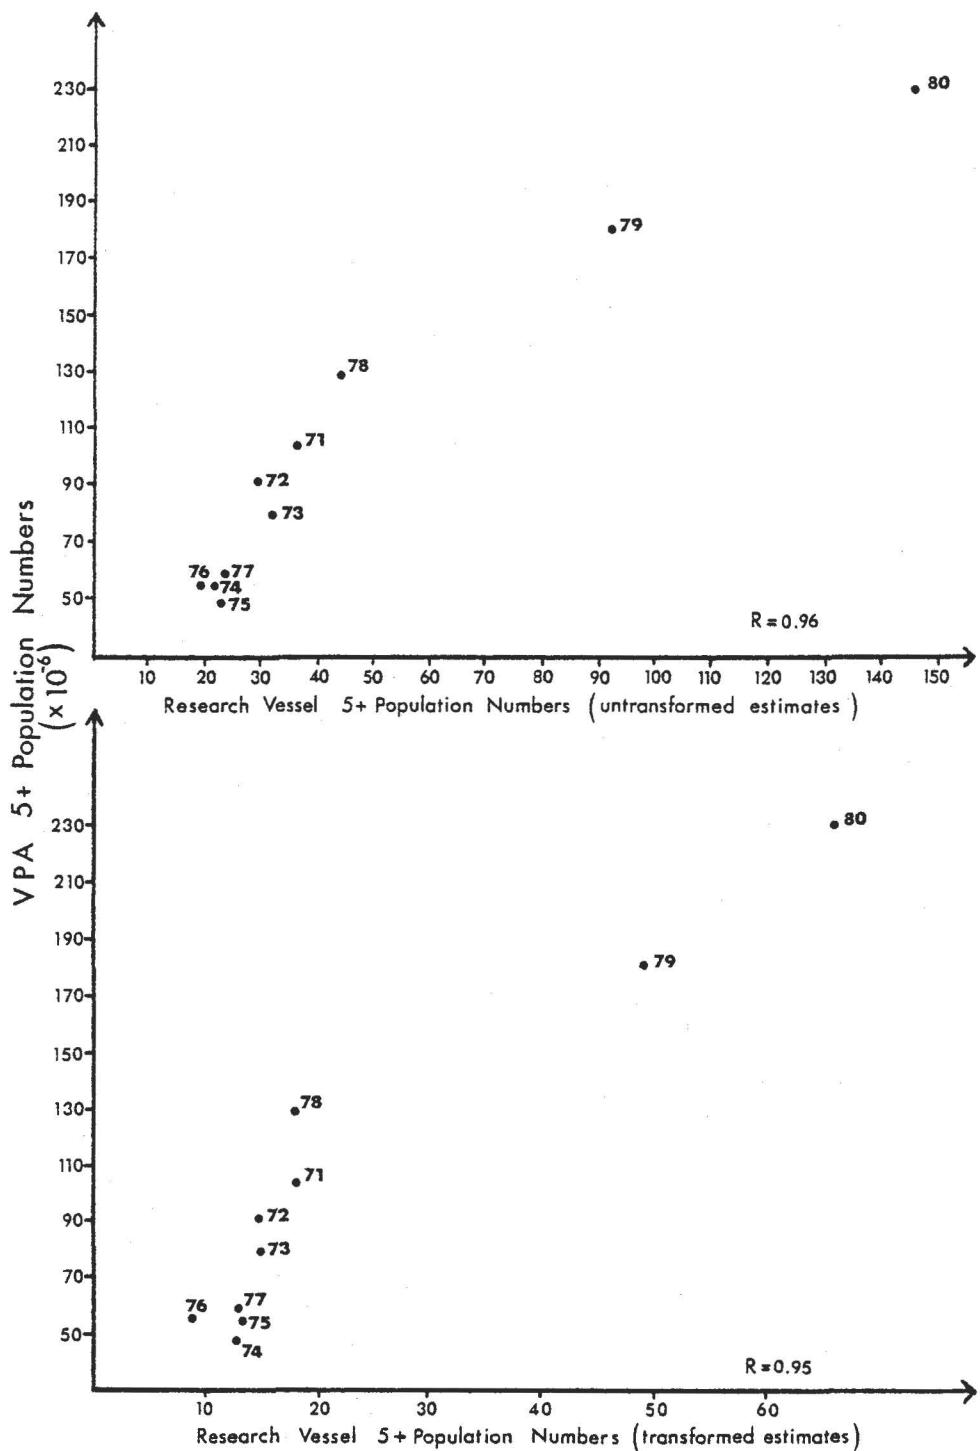

Figure 6. Relationship between VPA 5+ numbers and research vessel 5+ numbers.

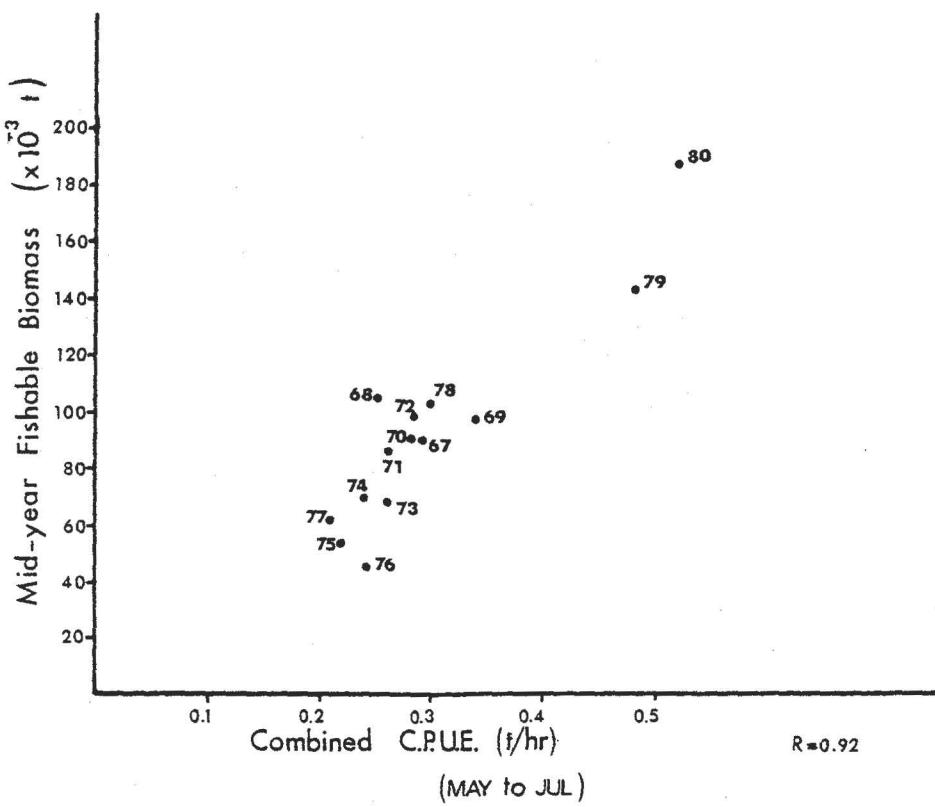

Figure 7. Relationship between mid-year fishable biomass from VPA and the combined CPUE index.

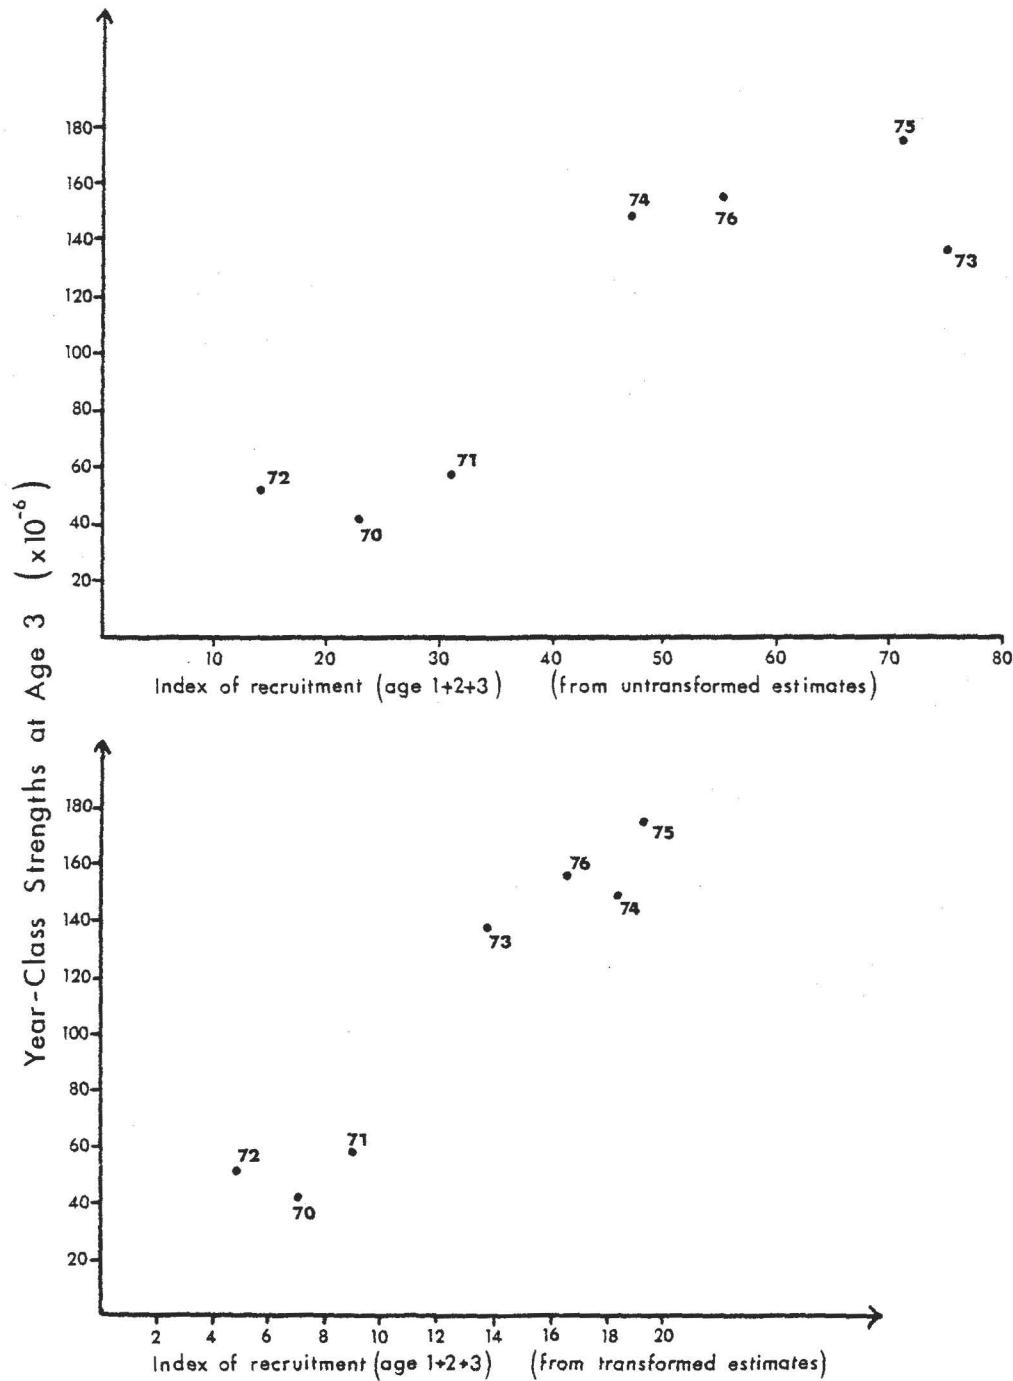

Figure 8. Relationships between VPA year-class strength estimates at age 3 and indices of recruitment.

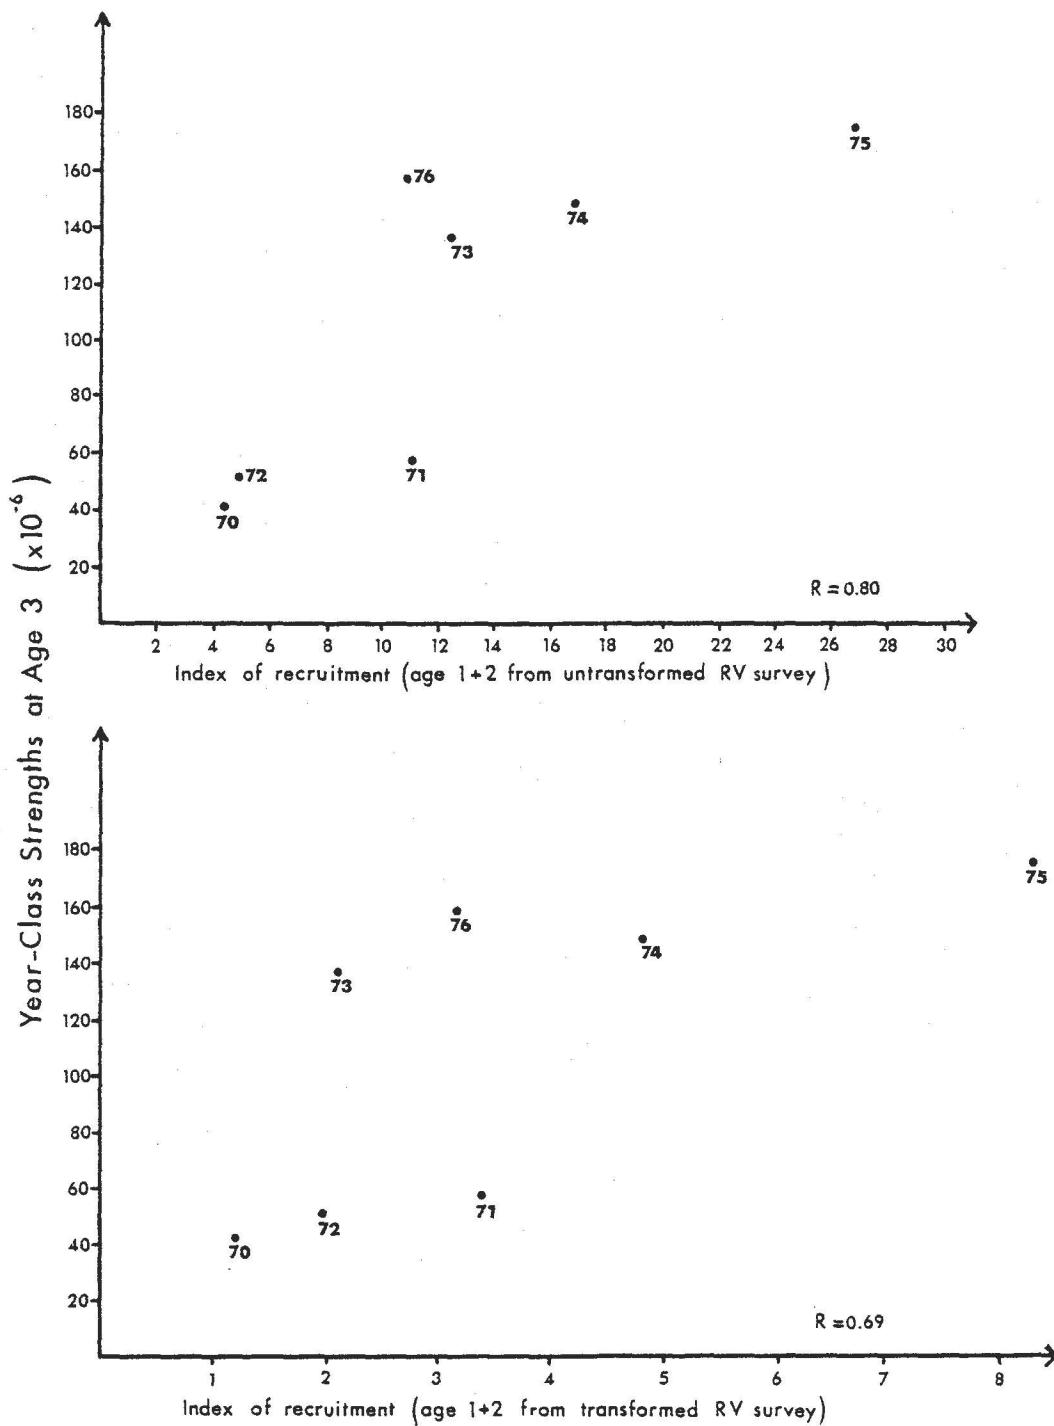

Figure 9. Relationships between VPA year-class strength estimates at age 3 and indices of recruitment.

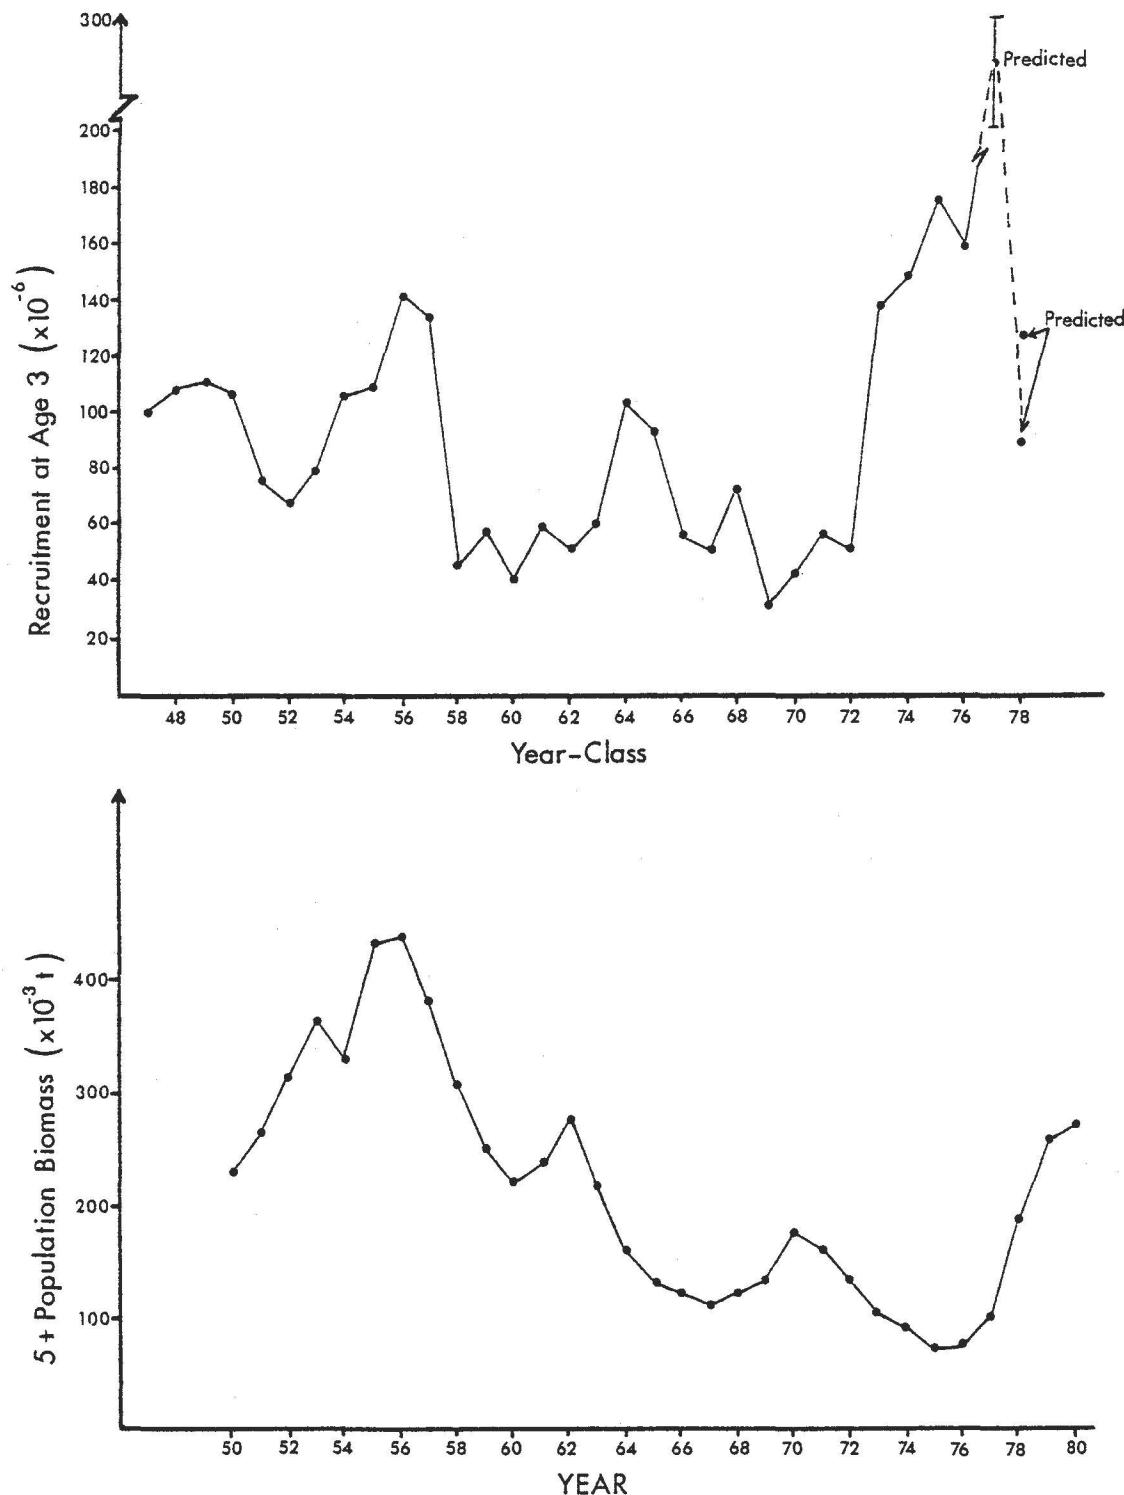

Figure 10. Distribution of VPA estimates of year-class strengths at age 3 (upper) and 5+ population biomass (lower).
