Assessment of Haddock on Eastern Georges Bank

S. Gavaris and L. Van Eeckhaute

Department of Fisheries and Oceans
Biological Station
531 Brandy Cove Road
St. Andrews, New Brunswick
Canada
E5B 2L9

¹ This series documents the scientific basis for the evaluation of fisheries resources in Canada. As such, it addresses the issues of the day in the time frames required and the documents it contains are not intended as definitive statements on the subjects addressed but rather as progress reports on ongoing investigations.

Research documents are produced in the official language in which they are provided to the Secretariat.

This document is available on the Internet at:

<http://www.dfo-mpo.gc.ca/csas/>

¹ La présente série documente les bases scientifiques des évaluations des ressources halieutiques du Canada. Elle traite des problèmes courants selon les échéanciers dictés. Les documents qu'elle contient ne doivent pas être considérés comme des énoncés définitifs sur les sujets traités, mais plutôt comme des rapports d'étape sur les études en cours.

Les documents de recherche sont publiés dans la langue officielle utilisée dans le manuscrit envoyé au Secrétariat.

Ce document est disponible sur l'Internet à:

Abstract

Haddock catches from eastern Georges Bank fluctuated around 5,000 t from 1985 to 1990. Under restrictive management measures, catches declined from over 6,400 t in 1991 to a low of about 2,100 t in 1995 and have since fluctuated between about 3,000 t and 4,000 t.

Total population biomass has steadily increased from near historic low levels of about 13,000 t in 1993 to about 50,000 t at the beginning of 2000 but remains below the average biomass during 1930-55 when productivity was higher. The recent increase is due principally to improved recruitment in the 1990's which produced the three strongest year-classes since 1978. The exploitation rate for fully recruited ages 4-8 has consistently been below the $F_{0.1}$ reference since 1995. Reduced fishing mortality and avoidance of small fish in the fisheries in recent years has resulted in increased survival of incoming year-classes and greater abundance at older ages.

Projected total Canada/USA yield at $F_{0.1} = 0.25$ in 2000 would be about 8,800 t and results in a probability of less than 30% for not achieving 20% biomass increase between 2000 and 2001. If fished at that rate in 2000, the adult biomass is projected to increase from 36,000 t to 46,000 t by the beginning of 2001. The population age structure shows good representation at all ages and a broad age range is expected to contribute to the 2000 catch.

Résumé

Les captures d'aiglefin de la partie est du banc Georges ont oscillé aux environs de 5 000 t de 1985 à 1990. L'imposition de mesures de gestion strictes a donné lieu à une baisse des captures qui sont passées de plus de 6 400 t en 1991 à 2 100 t environ en 1995, après quoi elles ont fluctué entre 3 000 t et 4 000 t environ.

La biomasse totale de la population s'est accrue de façon constante pour passer d'un minimum presque historique de 13 000 t environ en 1993 à 50 000 t environ au début de l'an 2000. Elle s'est ensuite maintenue, mais à une valeur en deçà de la moyenne de la période 1930-1955 où la productivité était supérieure. L'augmentation récente s'explique surtout par un meilleur recrutement au cours des années 1990 qui a donné lieu à l'apparition des trois meilleures classes d'âges depuis 1978. Le taux d'exploitation des groupes d'âges 4 à 8 pleinement recrutés a constamment été inférieur à la valeur cible du $F_{0.1}$ depuis 1995. Une mortalité par pêche réduite et la protection des poissons de petite taille au cours de la pêche des dernières années se sont traduites par un accroissement de la survie des classes d'âges à venir et une plus grande abondance des classes plus âgées.

Le rendement total prévu Canada/États-Unis au niveau $F_{0.1} = 0,25$ en 2000 est de 8 800 t environ et correspond à une probabilité de moins de 30 % de ne pas obtenir une augmentation de la biomasse de 20 % entre 2000 et 2001. Une pêche à ce niveau en 2000 devrait donner lieu à une augmentation de la biomasse des adultes qui passerait de 36 000 t à 46 000 t au début de 2001. La structure des âges de la population indique une bonne représentation de tous les groupes et on prévoit qu'une gamme d'âges étendue contribuera aux captures de l'an 2000.

Introduction

Since 1990, Canada has used eastern Georges Bank, fishery statistical unit areas 5Zej and 5Zem (Figure 1), as the basis for a management unit (Gavaris 1989), referred to as 5Zjm for brevity. In this assessment update, we included the latest information from the 1999 Canadian and USA fisheries. Results from the Department of Fisheries and Oceans, Canada (DFO) survey in the spring of 2000 and the National Marine Fisheries Service, USA (NMFS) surveys in the spring and fall of 1999 were incorporated. Methods similar to those used in the last assessment were applied to the updated information with a minor difference in that an age 9+ group was included in population calculations.

The Fishery

Commercial Catches

The haddock on Georges Bank have supported a commercial fishery since the early 1920s (Clark et al 1982). For details on the historical aspects of the Georges Bank haddock fishery see Gavaris and Van Eeckhaute (1998).

Under restrictive management measures, combined Canada/USA catches declined from over 6,400 t in 1991 to a low of about 2,100 t in 1995 and have since fluctuated between about 3,000 t and 4,000 t (Table 1, Figure 2). Greater catches in the late 1970s and early 1980s, ranging up to about 23,000 t, were associated with good recruitment. Substantial quantities of small fish were discarded in those years (Overholtz et al 1983). Catches subsequently declined and fluctuated about 5,000 t during the mid to late 1980s.

Total catches during the 1930s to 1950s ranged between 15,000 t and 40,000 t (Figure 3), averaging about 25,000 t (Schuck 1951, R. Brown pers. com.). Records of catches by unit area for the early 1960s period have not been located, however based on records for Subdivision 5Ze, catches probably attained record high levels of about 60,000 t during the early 1960s. Since the early 1970s catches have been substantially lower, generally fluctuating between 5,000 t and 10,000 t.

As in 1995 to 1998, Canadian catches in 1999 of 3,680 t were below the quota due to closure of the fisheries when the cod quotas were reached. During 1994 to 1999, all Canadian groundfish fisheries on Georges Bank remained closed from January to early June to protect spawning concentrations.

Weight of all 1999 Canadian landings were monitored at dockside and at-sea monitoring by observers accounted for about 10% of the cod and haddock catch. Comparison of observer samples with port samples did not reveal any persistent patterns to indicate that discarding or highgrading occurred commonly. Discarding and misreporting have been considered negligible since 1992.

In recent years, the Canadian fishery has been conducted by vessels using otter trawls, longlines, handlines and gillnets. During 1999, all vessels over 65 ft operated on enterprise

allocations, otter trawlers under 65 ft and fixed gear vessels 45-65 ft operated on individual quotas while fixed gear vessels under 45 ft operated on community quotas administered by local boards (Table 2). Most haddock were caught by otter trawlers and longliners in tonnage classes 1 and 2 (Table 3), approximately 35-65 ft. Total catch was greatest during June and July in 1999 (Table 4), while catches by otter trawlers peaked in June and catches by longliners peaked in August (Figure 5).

Fishery Sector	1995		1996		1997		1998		1999	
	Quota	Catch	Quota	Catch	Quota	Catch	Quota	Catch	Quota	Catch
Fixed gear <65'	592	357	1085	919	754	714	915	856	928	902

Source: Quota reports (will not match statistics exactly)

USA catches for 1999 were derived from logbooks coupled with dealer reports, as was done for 1994-98. Effort in the USA fishery was regulated using closed areas and Days-at-Sea limits (Table 2). To curtail targeting of haddock, a 500 lb trip limit was introduced in 1994 and raised to 1,000 lb in July 1996. The trip limit resulted in an increase in the discard rate. The trip limit has been adjusted periodically and in 1999 it was established at 3,000 lb/day, maximum of 30,000 lb/trip during January through April, 2,000 lb/day, maximum of 20,000 lbs/trip during May through October and 5,000 lb/day, maximum of 50,000 lbs/trip during November and December. The combination of area closures, effort restrictions, and trip limits has precluded most operators from making long trips to 5Zjm, with the result that USA catches from 5Zjm have been low since 1993. While Area II remained closed in 1999, landings from 5Zjm which come exclusively from tonnage classes 3 and 4 otter trawlers (Table 5), increased to 355 t and discards declined because the day and trip possession limits were increased. Catches by month were not available for recent years (Table 6).

Size and Age Composition

Comparison of length frequencies by quarter and gear collected at ports to those collected at sea did not reveal any persistent differences (Figure 4). The size and age composition of the 1999 Canadian fishery was characterised by port and at sea samples from all principle gears and all seasons (Table 7, Figure 5). The size composition of the catch peaked at 53 cm (21 in) for both otter trawlers and longliners (Figure 6). Gill-netters caught few haddock but they were larger. No sampling was available for discards of groundfish by-catch in the Canadian scallop fishery, though in previous years the amount caught has not been large.

Available port samples were inadequate to characterise the size and age composition of the USA fishery catch from eastern Georges Bank. Length composition from the USA fishery in the Great South Channel area were used with Canadian fishery and DFO survey age-length keys from eastern Georges Bank to derive the catch at age.

Survey and commercial otoliths were read by L. Van Eeckhaute for DFO and by N. Munroe for NMFS. Intra-reader agreement tests were available for the DFO reader and indicate that DFO age interpretations are consistent. Results of between reader comparisons raised some concerns of a small degree of bias which is being investigated, however these are not considered substantial enough to seriously compromise analyses (Appendix A).

The updated 1997 catch at age by quarter reported by Gavaris and Van Eeckhaute (1999) was erroneous. The correct 1997 catch at age along with the 1998 catch at age and the new 1999 catch at age by quarter for Canada and the USA (Table 8) were used to augment the 1969-96 results (Gavaris and Van Eeckhaute, 1997). Combined Canada/USA annual catch at age and average fishery weights at age are summarized in Tables 9 and 10 and Figure 7. In comparison to the average age composition of the catch during various earlier periods in this century, some of the older age groups were present at higher proportions in the 1999 catch (Figure 8). The 1996 year-class (age 3) dominated the 1999 catch, even though this age group is not fully recruited to the fishery. In contrast to pre-1994, few age 2 haddock were caught in 1999, due in part to the type of gear used and to avoidance of areas with small fish.

Abundance Indices

Commercial Catch Rates

Catch rates from the Canadian commercial fishery for selected trips (only those vessels which reported more than 1 t from 5Zjm during 1994 where cod, haddock and pollock comprised over 90% of the total catch) by tonnage class 2 and 3 otter trawlers and longliners increased from 1993 to 1995, remained relatively stable but variable from 1996 through 1998 and increased substantially in 1999 (Figure 9). Changes to regulations, gear modifications and varying fishing practices in recent years make comparison of catch rates from year to year difficult to interpret. Therefore, these were not used as indices of abundance.

Research Surveys

Surveys of Georges Bank have been conducted NMFS each fall since 1963 and each spring since 1968, and by DFO each spring since 1986. All these surveys use a stratified random design (Figures 10 and 11). For the NMFS surveys, two vessels have been employed and there was a change in the trawl door in 1985. Conversion factors (Table 11), derived experimentally from comparative fishing, have been applied to the survey results to make the series consistent. Additionally, two trawl nets were used on the NMFS spring survey, a modified Yankee 41 during 1973-81 and a Yankee 36 in other years, but no conversion factors are available for haddock.

The spatial distribution of catches for the most recent surveys of each series was similar to the distribution over the previous 5 year period. (Figures 12, 13 and 14). In spring, adults are more abundant in unit area 5Zej but age 1 fish are distributed broadly over unit areas 5Zej and 5Zem. In fall, adult haddock are more concentrated in the deeper waters along the

slopes of the Northeast Peak and the Northeast Edge, however, age 1 fish remain somewhat more widespread.

The percent of biomass, ages 3-8, on the Canadian side of 5Zjm from the three surveys was summarised for recent years (for method see Van Eeckhaute, et al 1999). During the NMFS fall surveys, almost all of the biomass occurred on the Canadian side. During the DFO spring surveys, generally conducted in late February, most of the biomass was on the Canadian side although the percentage was lower in 1992-93 and 2000. During the NMFS spring surveys, generally conducted in late March, the percentage on the Canadian side was typically lower but these results were more variable.

Year	Percentage of biomass on Canadian side		
	Feb.-Mar.	Mar.-Apr.	Oct.-Nov.
	DFO	NMFS	NMFS
1992	66	78	100
1993	67	42	99
1994	99	100	100
1995	98	59	100
1996	95	17	100
1997	90	91	100
1998	100	68	100
1999	98	41	100
2000	78	N/A	N/A

Age specific abundance patterns from the three surveys track year-class strengths fairly well (Tables 12, 13 and 14; Figure 15). Some year effects are evident as well, for example, the low spring catches observed for both the 1997 DFO and NMFS surveys. The index for ages 3-8 survey biomass peaked at record highs during the early 1960s. After declining to a record low in the early 1970s, it peaked again in the late 1970s, though at a lower level, and again during the mid to late 1980s at about half the level of the 1970s peak. Biomass increased from 1992 to 1996, fluctuated somewhat and increased again after 1998 (Figure 16).

Survey recruitment indices for ages 0, 1 and 2 indicate that the abundance of the 1996 year-class was comparable to the moderate 1983, 1985, 1987 and 1992 year-classes (Figure 17). These year-classes were considerably smaller than the strong 1975 and 1978 year-classes and the very strong 1962 and exceptional 1963 year-classes. The 1997 year-class is weaker but the 1998 year-class may be moderate to strong. First indications for the 1999 year-class suggest that it may also be moderate.

There were no persistent trends in weight at age derived from the DFO survey. Average weight at age of haddock from the 1989 to 1991 year-classes were higher than adjacent

year-classes in both the surveys (Figure 18) and the commercial fisheries (Figure 19), giving the false impression of a declining trend in recent years. The method of calculation of the weights at age from the DFO spring survey were given in Gavaris and Van Eeckhaute (1998) and were derived from actual weights observed during the survey and weighted by population numbers at length and age (Table 15). Fishery weights at age (Table 10; Figure 19) are derived from a length-weight relationship (Waiwood and Neilson 1985). In some cases, the mean weight at age in the catch is larger than the population mean weight at age at the beginning of the following year for the same cohort. This effect was investigated by an analysis of lengths at age from survey and fishery data and found to be mostly attributable to bottom trawl gear changes which resulted in a change in partial recruitment since 1994. However, some discrepancies in weights at age were more persistent and may be due to problems associated with the length weight equations and gutted to round weight conversion factors. Further investigation is warranted (Appendix B).

Estimation of Stock Parameters

Calibration of Virtual Population Analysis (VPA)

The adaptive framework, ADAPT, (Gavaris 1988) was used to calibrate the virtual population analysis with the research survey abundance information. An investigation of model formulations and model assumptions was conducted by Gavaris and Van Eeckhaute (1998) where details of model equations and the objective function are provided. The model formulation adopted assumed that the random error in the catch at age was negligible. The errors in the abundance indices were assumed independent and identically distributed after taking natural logarithms of the values. The annual natural mortality rate, M , was assumed constant and equal to 0.2. Similar model assumptions and methods were applied to the updated information here. Minor differences in the handling of zero terminal catches for a year-class were implemented as a refinement to the software to afford more flexibility. The population abundance for the 9+ age group was calculated but not calibrated to the indices. In the first quarter of the first year, the 9+ abundance calculation was based on the assumption that the fishing mortality for the 9+ age group was equal to the population weighted fishing mortality for ages 4 - 7. In the first quarter of subsequent years, the 9+ abundance was calculated as the sum of the age 8 and age group 9+ abundances at the end of the last quarter of the previous year.

The VPA used quarterly catch at age, $C_{a,t}$, for ages $a = 0, 1, 2 \dots 8, 9+$, and time $t = 1969.0, 1969.25, 1969.5, 1969.75, 1970.0 \dots 1999.75$, where t represents the beginning of the time interval during which the catch was taken. The VPA was calibrated to bottom trawl survey abundance indices, $I_{s,a,t}$, for

$s =$ DFO spring, ages $a = 1, 2, 3 \dots 8$, time $t = 1986.16, 1987.16 \dots 1999.16, 2000.0$

$s =$ NMFS spring (Yankee 36), ages $a = 1, 2, 3 \dots 8$, time $t = 1969.29, 1970.29, 1971.29, 1972.29, 1982.29, 1983.29 \dots 1999.29$

$s =$ NMFS spring (Yankee 41), ages $a = 1, 2, 3 \dots 8$, time $t = 1973.29, 1974.29 \dots 1981.29$

$s = \text{NMFS fall, ages } a = 0, 1, 2 \dots 5, \text{ time } t = 1969.69, 1970.69 \dots 1999.69$

Since forecast projections were required for the entire year 1999, the DFO spring survey in 2000 was designated as occurring at time 2000.0 instead of 2000.16. The NMFS fall survey captures young of the year and that information is included as 0 group, but older haddock appear less available during this season. Survey indices for older ages where catches were sparse and there were frequent occurrences of zero catches were not included. Zero observations for abundance indices were treated as missing data as the logarithm of zero is not defined. During years when discarding was high, survey information was used along with interviews to obtain estimates of the USA catch. This lack of complete independence between catch and survey data does not influence population estimates but may deflate variance estimates marginally.

Statistical properties of estimators were obtained from model conditioned non-parametric bootstrap of the residuals (Efron and Tibshirani 1993). The population abundance estimates show a large relative error and substantial bias at ages 1 and 2 while the relative error for other ages is about 30% and the bias is small (Table 16). The average magnitude of residuals is large and though several large residuals can be identified, the respective observations do not appear influential and should not impact parameter estimates of current abundance (Figures 20-24). Some patterns in the residuals (by cohort and by age) merit further investigation.

Retrospective Analysis

Assessment results for several other stocks have identified a discrepancy between past and current estimates of stock status (retrospective pattern). This stock assessment does not suffer from a retrospective pattern. Figure 25 tracks successive estimates of year-class abundance at age and shows that estimates are fairly stable although there is sometimes a substantial change after the first estimate of a year-class when more data becomes available, as evidenced for the 1992 and 1996 year-classes. There were no trends of concern in the 3+ biomass pattern and the 4+ F when weighted by population numbers (Figure 26).

Stock Status

The results from the calibrated VPA were considered appropriate on which to base the status of the stock. For each cohort, the terminal population abundance estimates from ADAPT were adjusted for bias and used to construct the history of stock status (Tables 17-18). This approach for bias adjustment, in the absence of an unbiased point estimator with optimal statistical properties, was considered preferable to using the biased point estimates (O'Boyle 1998). Bias adjusted VPA results were based on bootstrap statistics. The weights at age from the DFO spring survey (Table 15) were used to calculate beginning of year population biomass (Table 19). A weight of 2.4 kg, which was midway between the age 6 and 8 weight for that cohort, was used for age 7 in 1995 as no data were available for that age group. For 1969-85, the 1986-95 average weight at each age was used.

Population biomass (ages 1+) has steadily increased from near historic low levels of about 13,000 t in 1993 to about 50,000 t at the beginning of 2000 (Figure 27). The recent increase, due principally to the 1992 and 1996 year-classes, but also supported by the 1991 and 1993 year-classes, was enhanced by increased survivorship and by reduced capture of small fish in the fisheries. The biomass increase is expected to be sustained by the 1998 year-class. The adult biomass (ages 3+) trend is similar to the ages 1+ trend, with a 20% increase from 1999 to 2000, due largely to recruitment of the 1996 year-class.

Population biomass during the late 1970s and early 1980s was almost 50,000 t, due to recruitment of the strong 1975 and 1978 year-classes whose abundance was estimated at about 50 million. However, biomass declined rapidly in the early 1980s as subsequent recruitment was poor and these two year-classes were fished intensely at a young age.

The strength of the 1996 year-class was estimated to be about 18 million at age 1, the second highest since 1978 (Figure 28). The 1991, 1993, 1995 and 1997 year-classes appeared weaker at between 6 and 10 million. The 1998 year-class was estimated to be relatively strong at about 29 million recruits, the strongest since 1978. Preliminary indications for the 1999 year-class suggest it may be the third largest since 1978 at about 16 million.

Exploitation rate for fully recruited ages 4-8 has consistently been below that corresponding to $F_{0.1}$ (20%) since 1995 (Figure 29). Historically, exploitation rate has generally exceeded that corresponding to $F_{0.1}$ and showed a marked increase between 1989 and 1993 to almost 50%, the highest level observed. Reduced fishing mortality in recent years has resulted in increased survival of incoming year-classes. The number of haddock of the 1992 year-class surviving to age 8 was over four times that of the equally abundant 1983 year-class, and about the same as that of the 1975 or 1978 year-classes which were more than 3 times as abundant (Figure 30). In both absolute numbers and percent composition, the population structure displays a broad representation of age groups, reflecting improved recruitment and lower exploitation since 1995 (Figure 31).

Gains in fishable biomass may be partitioned into those associated with somatic growth of haddock, which have previously recruited to the fishery, and those associated with new recruitment to the fishery (Rivard 1980). We used age 2 as a convenient age of first recruitment to the fishery. Since 1993, biomass gains from growth and from recruitment have exceeded the losses due to natural deaths and to fishery harvest, resulting in net increase (Figure 32). Growth of fish is the dominant component of the biomass gain but recruitment accounts for significant portions when stronger year-classes enter (Figure 33).

Prognosis

Yield projections were done using the bias adjusted 2000 beginning of year population abundance estimates. The abundance of the 2000 year-class was assumed to be 6 million at age 0. Partial recruitment to the fishery for ages 1, 2 and 3, fishery weights at age and beginning of year population weights at age were averaged over the previous 5 years for use in the 2000 forecasts (Table 20). Projected total Canada/USA yield at $F_{0.1} = 0.25$ in 2000

would be about 8,800 t. If fished at $F_{0.1}$ in 2000, the adult biomass is projected to increase from 36,000 t to 46,000 t by the beginning of 2001. The 1996 year-class (age 4) is expected to comprise almost 40% of the total yield in 2000. The 1992 –1995 (ages 5-8) and 1997 (age 3) year-classes will contribute almost equally to the remaining yield (Figure 34).

Uncertainty about year-class abundance generates uncertainty in forecast results. This uncertainty was expressed as risk of achieving reference targets. For example, a combined Canada/USA catch of 8,000 t in 2000, about twice what was caught in 1999, results in about 25% probability that fishing mortality rate will exceed $F_{0.1}$ and a low probability that the adult biomass will decrease. At this yield there is a probability of about 10% of not achieving 10% biomass increase and a probability of 25% of not achieving 20% biomass increase (Figure 35). A catch corresponding to $F_{0.1}$ in 2000 results in a probability of less than 30% of not achieving 20% biomass increase between 2000 and 2001.

These calculations do not include uncertainty due to variations in weight at age, partial recruitment to the fishery and natural mortality, or systematic errors in data reporting and model mismatch.

Management Considerations

A Canadian quota of 3,900 t in 1999 was expected to result in a negligible chance of exceeding $F_{0.1}$ and a 50% chance of getting 10% growth in the stock. The Canadian catch in 1999 was about 3,700 t and resulted in a fishing mortality about half of $F_{0.1}$ and an increase in adult biomass of about 20%.

Data were available to approximate the age composition of the catch from unit areas 5Zej and 5Zem in order to reconstruct an illustrative population analysis for the period between 1930 and 1955 which is suitable for comparing productivity. The results indicated that although biomass has been increasing, it remains below the average biomass during 1930 to 1955 when productivity was higher (Figure 36).

The pattern of recruitment indicates that the chance of a strong year-class is significantly reduced for adult biomass below about 40,000 t (Figure 37). Since 1969, only the 1975 and 1978 (and possibly the 1998) year-classes have been near the average abundance of year-classes observed during the 1930 to 1955 period. Examination of the recruits per spawning biomass ratio suggests that survivorship to age 1 for several years during the 1980s may have been lower than the norm (Figure 38). The present survivorship appears comparable to that of the 1930s to 1950s period, suggesting that higher recruitment might result if the biomass increases.

Attributes like exploitation rate and biomass respond directly and immediately to management actions and can be used to compare consequences of alternative harvest yields. The projections above show those results. Other attributes, like recruitment, age structure and spatial distribution reflect possible fluctuations in the productive potential and can be used to qualify reference points and acceptable risk. Biomass can be considered both a response attribute and a productivity attribute. The states of these attributes suggests that

while conditions have improved, further rebuilding is required, therefore some moderation is indicated.

Cod and haddock are often caught together in groundfish fisheries. However, their catchabilities to the fisheries differ and they are not necessarily caught in proportion to their relative abundance. With current fishing practices, exploitation of haddock at $F_{0.1}$ may compromise the achievement of rebuilding objectives for cod.

¹ 1895 t excluded because of suspected area misreporting.

Table 2. Regulatory measures implemented for the 5Z and 5Zjm fishery management units by the USA and Canada, respectively, from 1977, when jurisdiction was extended to 200 miles for coastal states, to the present.

	USA	Canada
1977-82	Mesh size of 5 1/8" (140 mm), seasonal spawning closures, quotas and trip limits.	
1982-85	All catch controls eliminated, retained closed area and mesh size regulations, implemented minimum landings size (43 cm).	First 5Ze assessment in 1983.
1984 Oct.	Implementation of the 'Hague' line .	
1985	5 1/2" mesh size,. Areas 1 and 2 closed during February-May.	
1989		Combined cod-haddock-pollock quota for 4X-5Zc
1990		5Zjm adopted as management unit. For MG < 65 ft. – trip limits with a 30% by-catch of haddock to a maximum of 8 trips of 35,000 lbs per trip between June 1 and Oct. 31 and 130 mm square mesh required. Fixed gear required to use large hooks until June
1991	Established overfishing definitions for haddock.	MG < 65 ft similar to 1990 but mesh size increased to 145 mm diamond.
1992		Introduction of ITQs and dockside monitoring.
1993	Area 2 closure in effect from Jan 1-June30.	OT fishery permitted to operate in Jan. and Feb. Increase in use square mesh.
1994	Jan.: Expanded Area 2 closure to include June and increased extent of area. Area 1 closure not in effect. 500 lb trip limit. Catch data obtained from mandatory log books combined with dealer reports (replaces interview system). May: 6" mesh restriction. Dec.: Area 1,2 closed year-round.	Spawning closure extended to Jan. 1 to May 31. Fixed gear vessels must choose between 5Z or 4X for the period of June to September. Small fish protocol. Increased at sea monitoring. OT > 65 could not begin fishng until July 1. Predominantly square mesh by end of year.
1995		All OT vessels using square mesh. Fixed gear vessels with a history since 1990 of 25t or more for 3 years of cod, haddock pollock, hake or cusk combined can participate in 5Z fishery. ITQ vessel require at least 2t of cod and 8t of haddock quota to fish Georges.
1996	July: Additional Days-at-Sea restrictions, trip limit raised to 1000 lbs.	Fixed gear history requirement dropped.
1997	May: Additional scheduled Days-at-sea restrictions. September: Trip limit raised to 1000 lbs/day, maximum of 10,000 lbs/trip.	Vessels over 65 ft operated on enterprise allocations, otter trawlers under 65 ft on individual quotas, fixed gear vessels 45-65 ft on self-administered individual quotas and fixed gear vessels under 45 ft on community quotas administered by local boards.
1998	Sept. 1: Trip limit raised to 3000 lbs/day, maximum of 30,000 lbs/trip.	Fixed gear vessels 45-65 ft operated on individual quotas.
1999	May 1: Trip limit 2,000 lbs/day, max. 20,000 lbs/trip. Square mesh size increased to 6.5". June 15: Scallop exemption fishery in Closed Area II. Nov. 5: Trip limit 5,000 lbs/day, max. 50,000 lbs/trip. Nov. 15: New overfishing definitions and harvest control rules.	Same as 1997 and 1998.

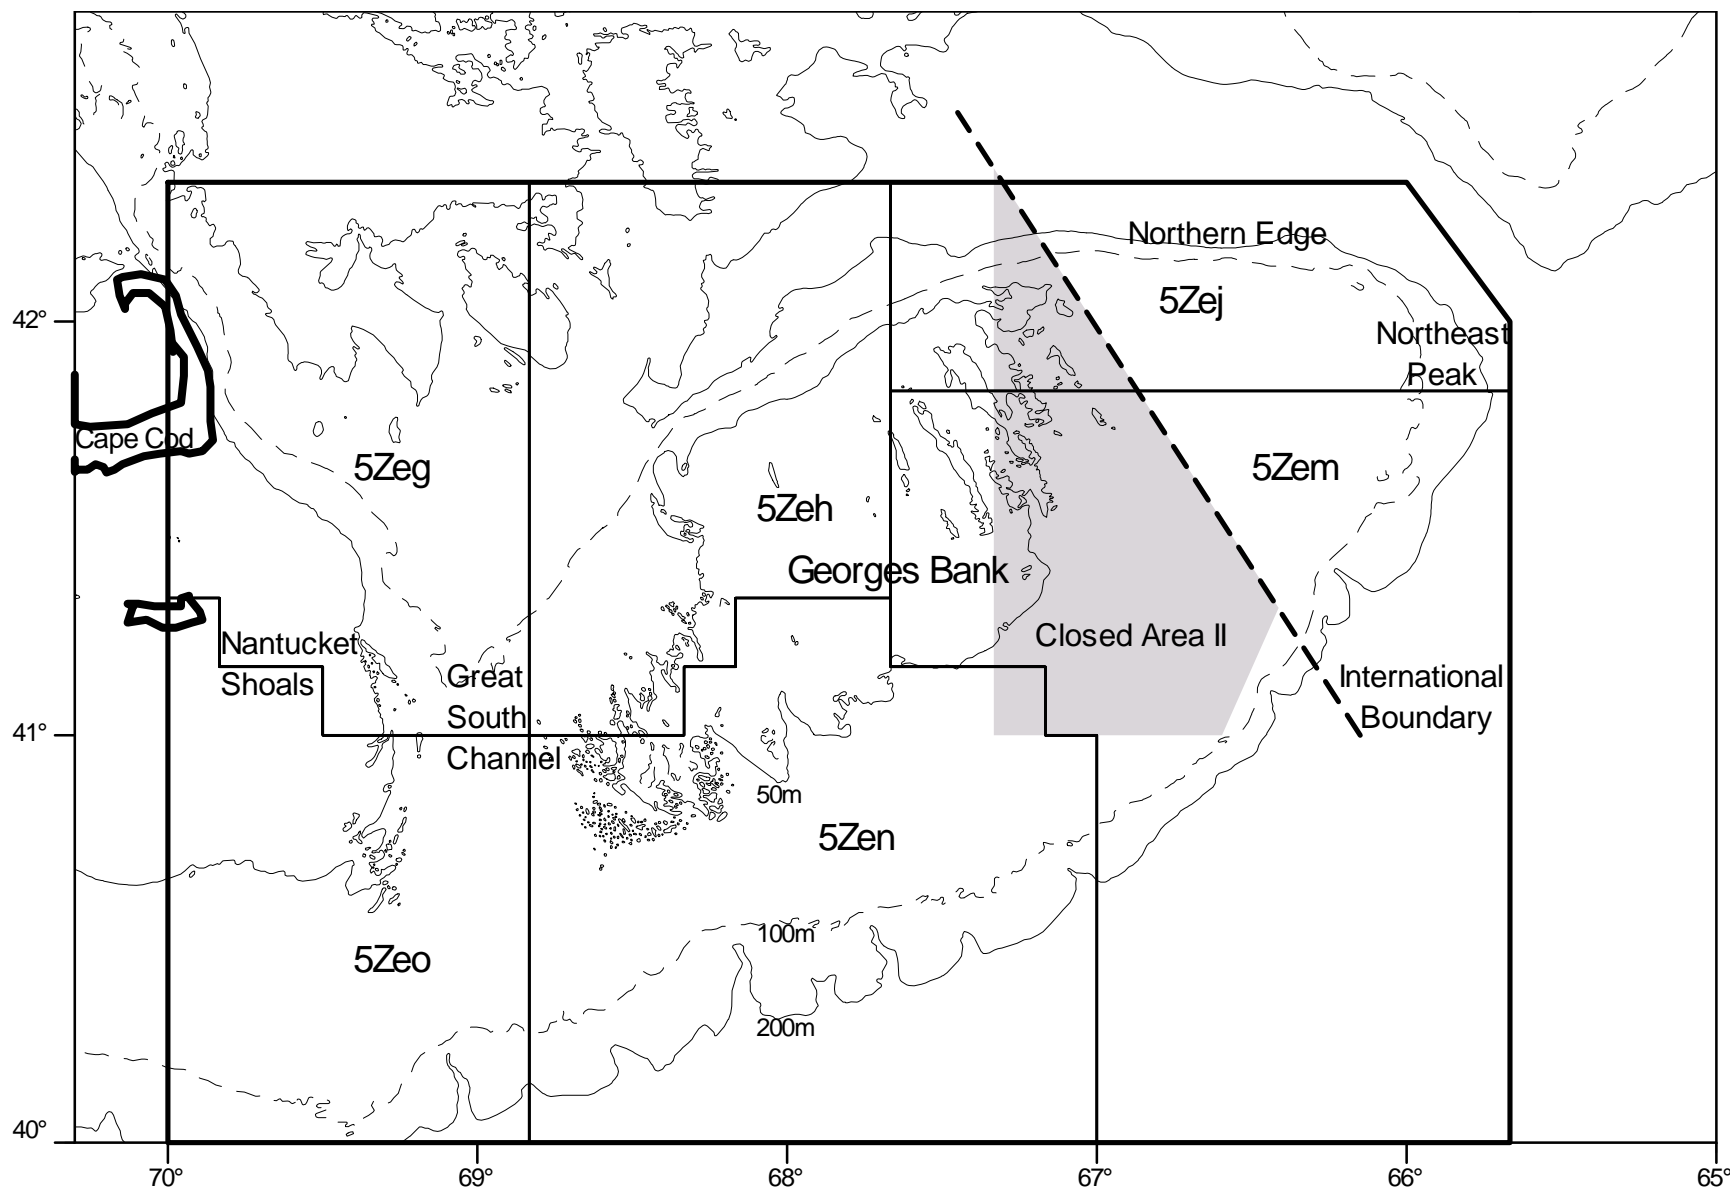

Figure 1. Fisheries statistical unit areas in NAFO Subdivision 5Ze.

Figure 2. Nominal catch of haddock in unit areas 5Zjm.

Figure 3. Historic catch of haddock in 5Zjm compared to recent catches.

Figure 4. Comparison of length frequencies from port samples and sea samples by quarter and gear (LL = longline, OTIN = otter trawl tonnage classes 1-3, OTOF = otter trawl tonnage classes 4-5).

Figure 5. Haddock catches in 5Zjm by month and gear for the Canadian commercial fishery in 1999 (wide gray bars) with sampling levels (narrow black bars).

Figure 6. Catch at length by the principal Canadian 5Zjm commercial haddock fisheries in 1999.

Figure 7. Total commercial catch at age (numbers) of haddock from unit areas 5Zjm. The bubble area is proportional to magnitude (see Table 9).

Figure 8. Age composition of the haddock catch for the Canadian 5Zjm commercial fishery in 1999 compared to the average age composition for the total catch of all fisheries during three earlier periods.

Figure 9. Catch rates for haddock from the Canadian commercial fishery in 5Zjm. (LL = longline, OT = otter trawl, TC = tonnage class).

Figure 10. Stratification scheme used for NMFS surveys. The 5Zjm management area is indicated by shading.

Figure 11. Stratification scheme used for the DFO survey. The 5Zjm management area is indicated by shading.

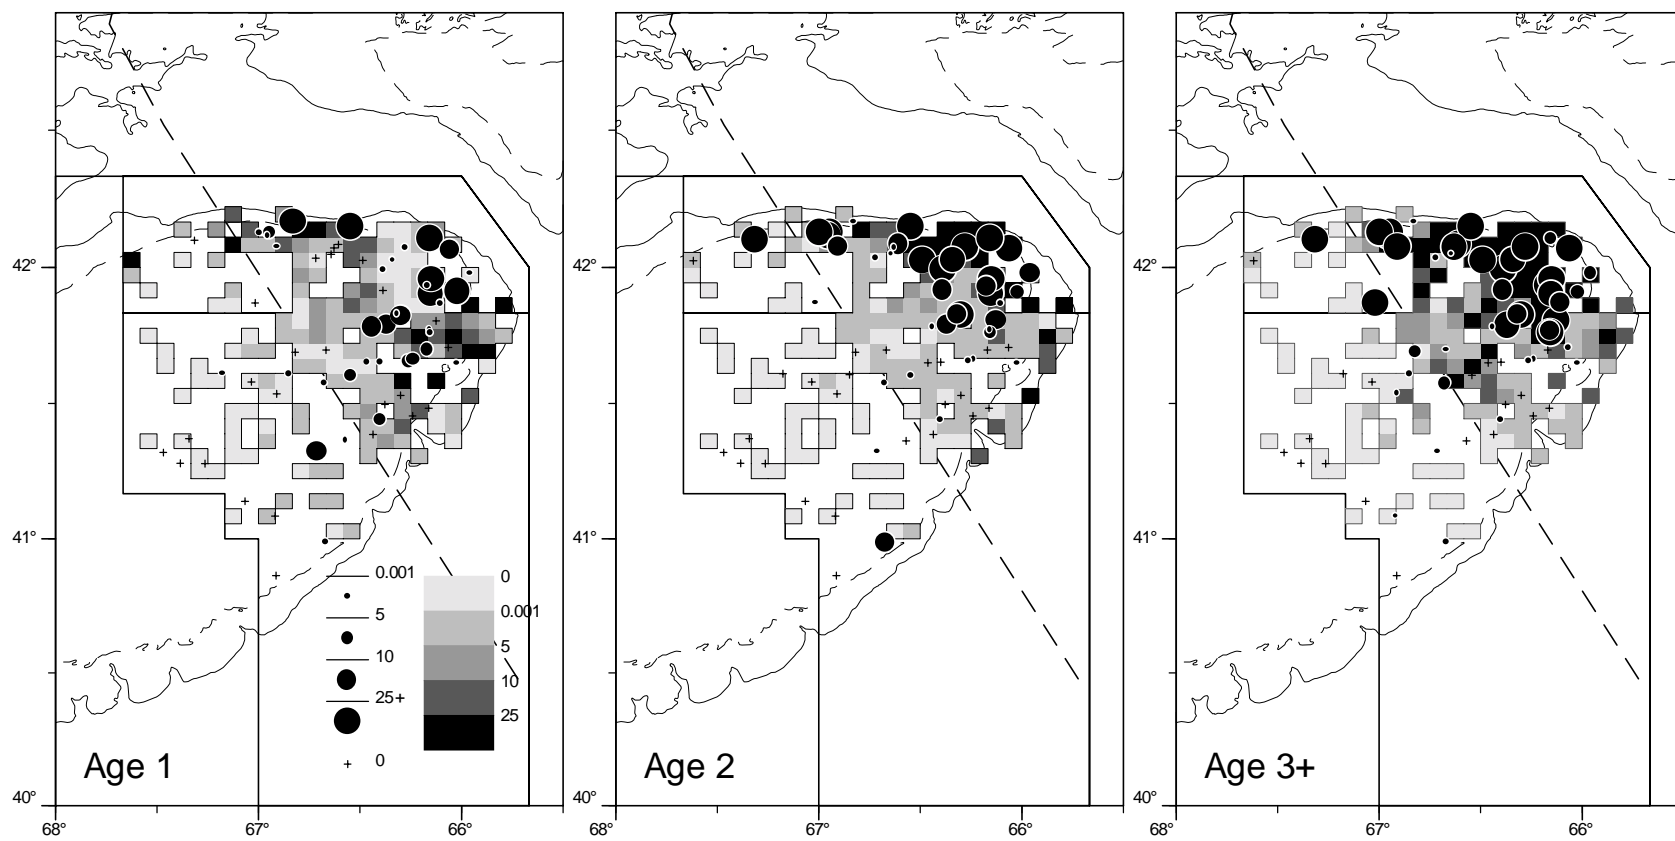

Figure 12. Distribution of 5Zjm haddock abundance (number/tow) as observed from the **DFO spring** survey. The squares are shaded relative to the average catch for 1995 to 1999. The expanding symbols represent the 2000 survey catches.

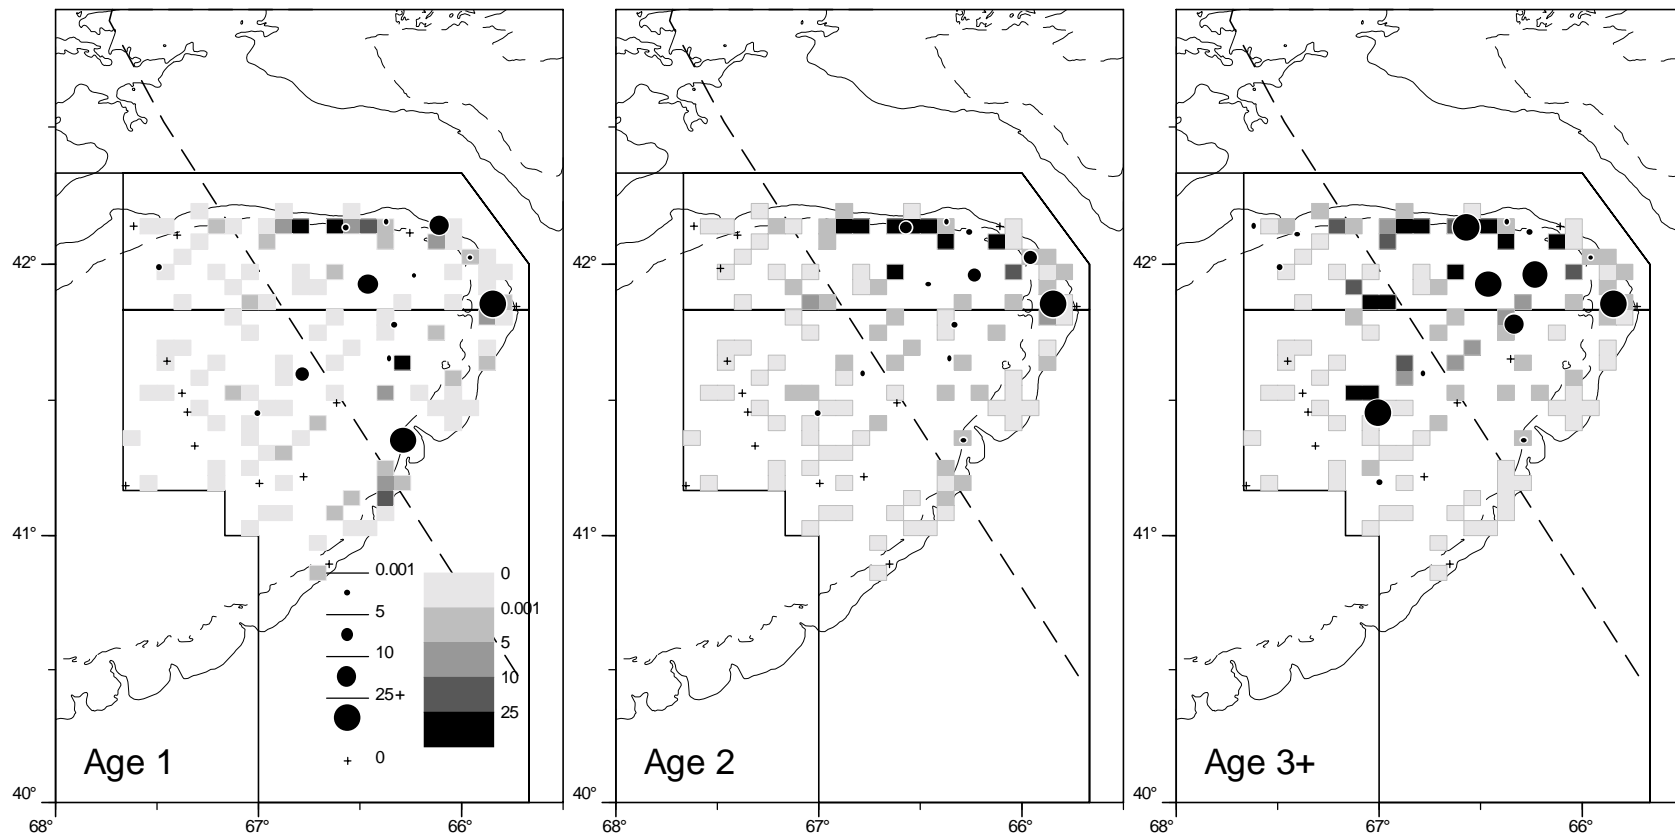

Figure 13. Distribution of 5Zjm haddock abundance (number/tow) as observed from the **NMFS spring** survey. The squares are shaded relative to the average catch for 1994 to 1998. The expanding symbols represent the 1999 survey catches.

Figure 14. Distribution of 5Zjm haddock abundance (number/tow) as observed from the **NMFS fall** survey. The squares are shaded relative to the average catch for 1994 to 1998. The expanding symbols represent the 1999 survey catches.

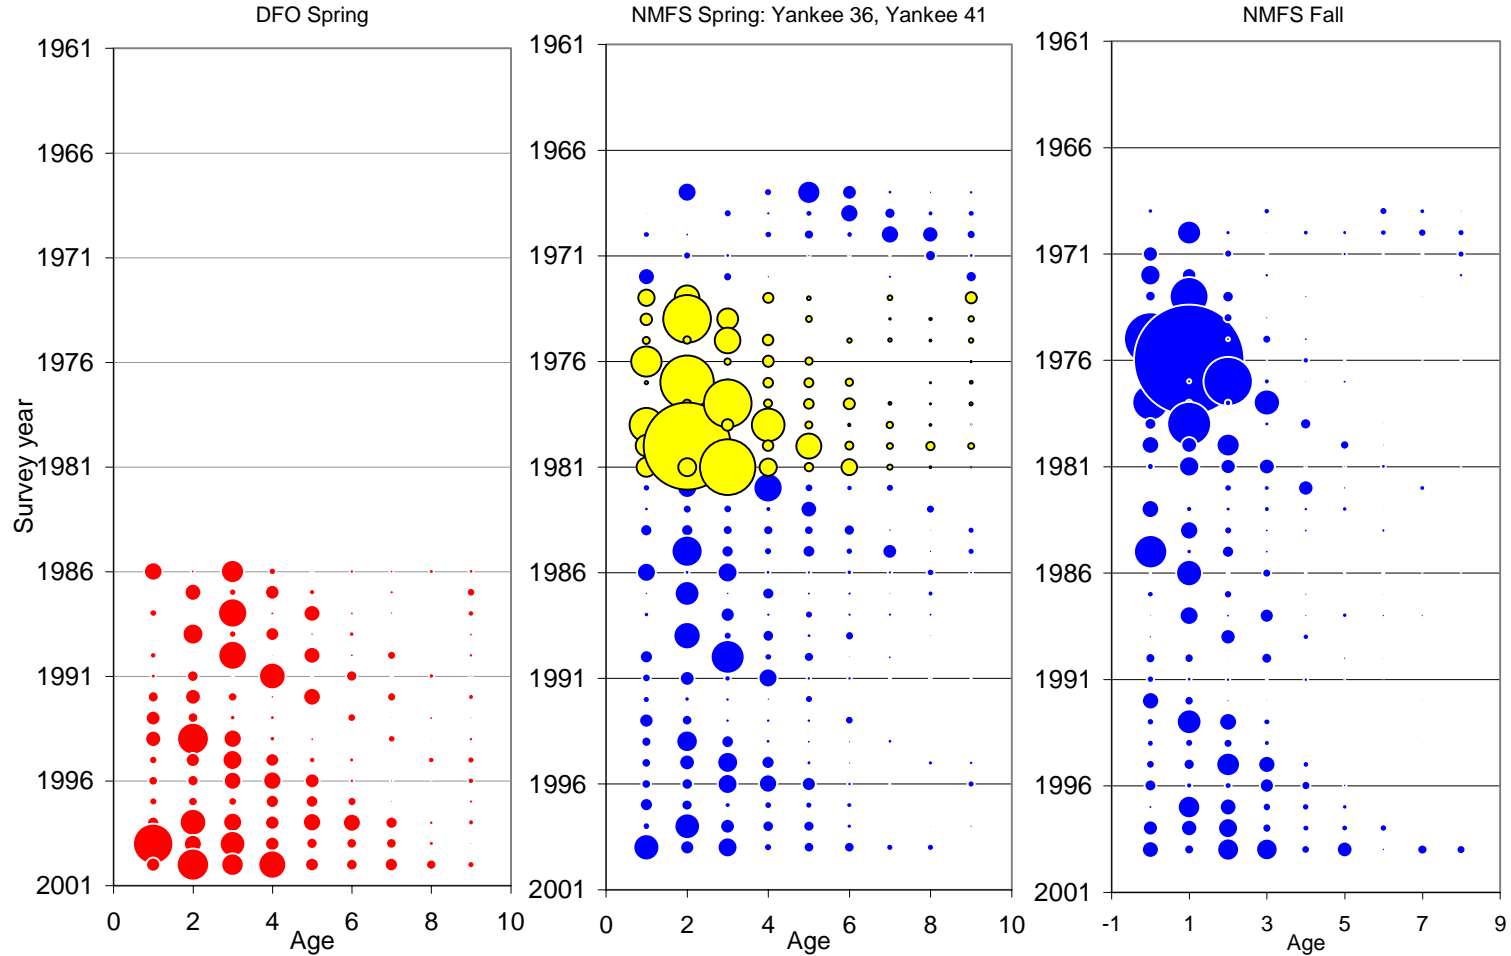

Figure 15. Estimated abundance at age (numbers in 000's) of haddock for the DFO and NMFS spring surveys and the NMFS fall survey. Bubble area is proportional to magnitude (see Tables 12-14). Conversion factors to adjust for changes in door type and survey vessel were applied to the NMFS surveys. From 1973-81, a 41 Yankee trawl was used for the NMFS spring survey while a 36 Yankee was used in the other years. Symbol size has not been adjusted between surveys for the catchability of the survey.

Figure 16. Biomass for ages 3-8 from the NMFS and DFO research surveys (adjusted by calibration constants) for haddock in unit areas 5Zjm..

Figure 17. Year-class abundance for ages 0, 1 and 2 from the NMFS fall and ages 1 and 2 from the NMFS and DFO spring research surveys (adjusted by calibration constants) for haddock in unit areas 5Zjm.

Figure 18. Weight at age for haddock in unit areas 5Zjm derived from the DFO spring surveys.

Figure 19. Weight at age for haddock in unit areas 5Zjm derived from the commercial fisheries.

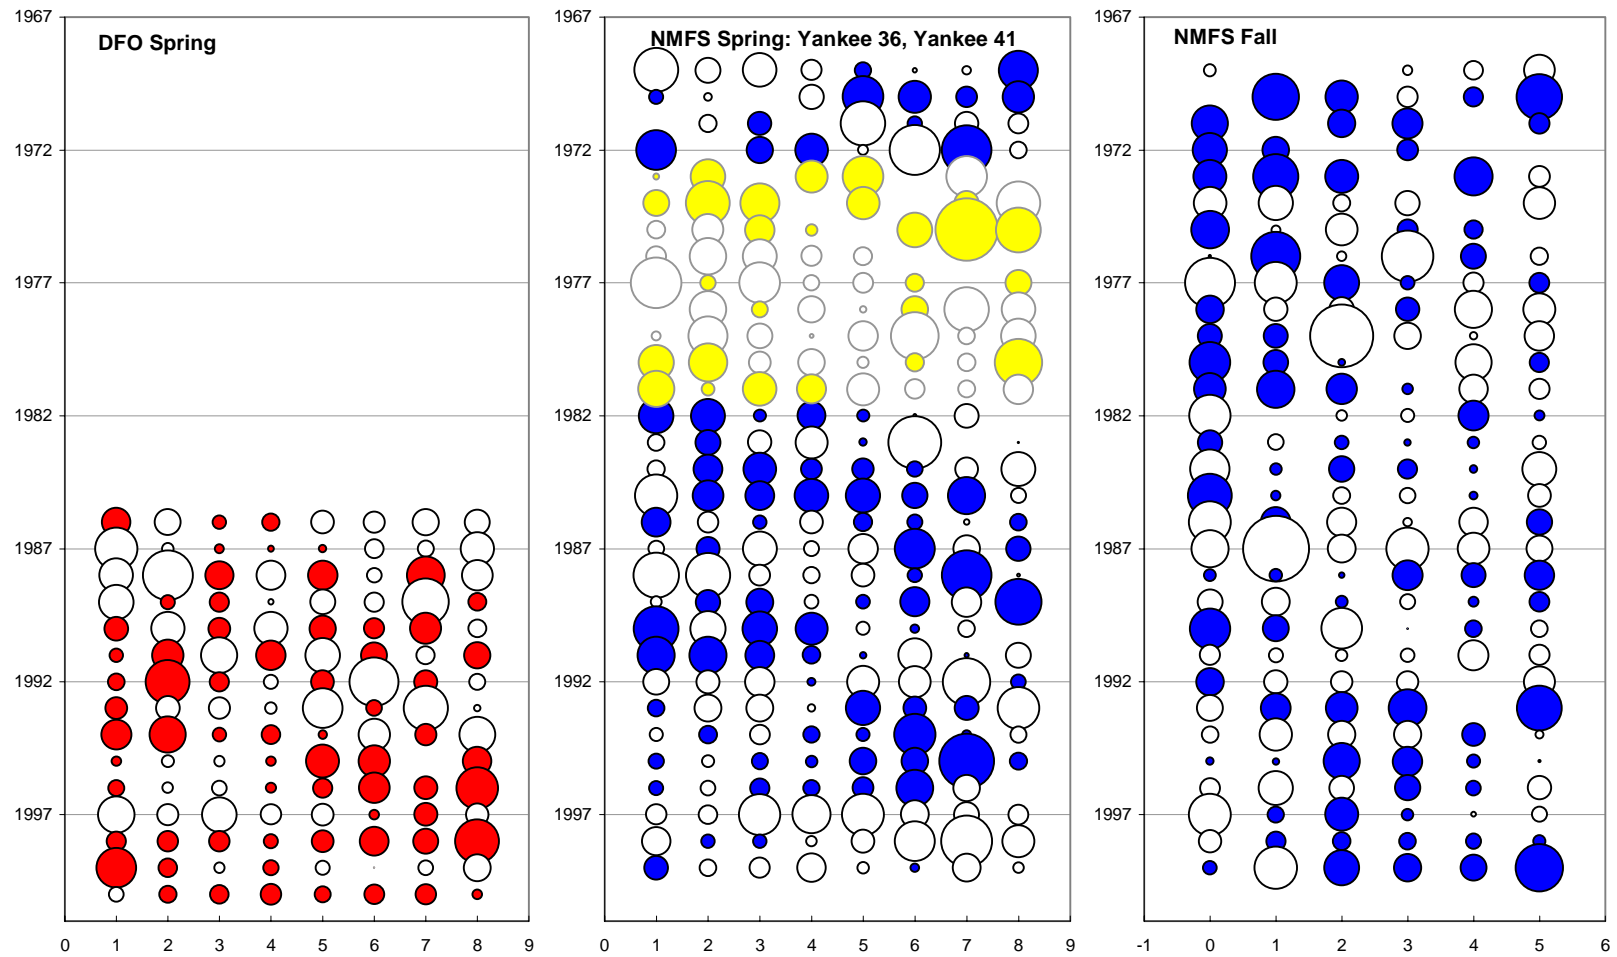

Figure 20. Residuals by year and age group for each research survey index. Solid symbols indicate positive values, open symbols indicate negative values. Bubble area is proportional to magnitude.

Figure 21. Age by age plots of the observed and predicted ln abundance index versus ln population numbers for haddock in unit areas 5Zj and 5Zm from the **DFO spring** survey.

Figure 22. Age by age plots of the observed and predicted \ln abundance index versus \ln population numbers for haddock in unit areas 5Zj and 5Zm from the **NMFS spring** survey with a Yankee 36 net.

Figure 23. Age by age plots of the observed and predicted ln abundance index versus ln population numbers for haddock in unit areas 5Zj and 5Zm from the NMFS spring survey with a Yankee 41 net.

Figure 24. Age by age plots of the observed and predicted \ln abundance index versus \ln population numbers for haddock in unit areas 5Zj and 5Zm from the NMFS fall survey.

Figure 25. Successive estimates of year-class abundance as additional years of data were included in the assessment did not display any persistent trends.

Figure 26. Retrospective estimates of biomass and fishing mortality did not display any persistent trends for over or under estimation as successive years of data were excluded in the assessment.

Figure 27. Beginning of year biomass for haddock in unit areas 5Zjm.

Figure 28. Number of age 1 recruits for haddock in unit areas 5Zjm.

Figure 29. Exploitation rate for haddock ages 4 to 8 in unit areas 5Zjm.

Figure 30. Decay of the 1992, 1996 and 1998 year-classes of the 5Zjm haddock population compared to the 1983, 1975 and 1978 as they progress through the fishery.

Figure 31. Comparison of age composition and absolute abundance of the 5Zjm haddock population in 2000 to earlier periods.

Figure 32. Surplus production of 5Zjm haddock available to the commercial fishery compared to amount actually harvested.

Figure 33. Amount of productivity attributable to growth of ages 2 to 8 5Zjm haddock and the amount contributed by recruitment of age 2 haddock.

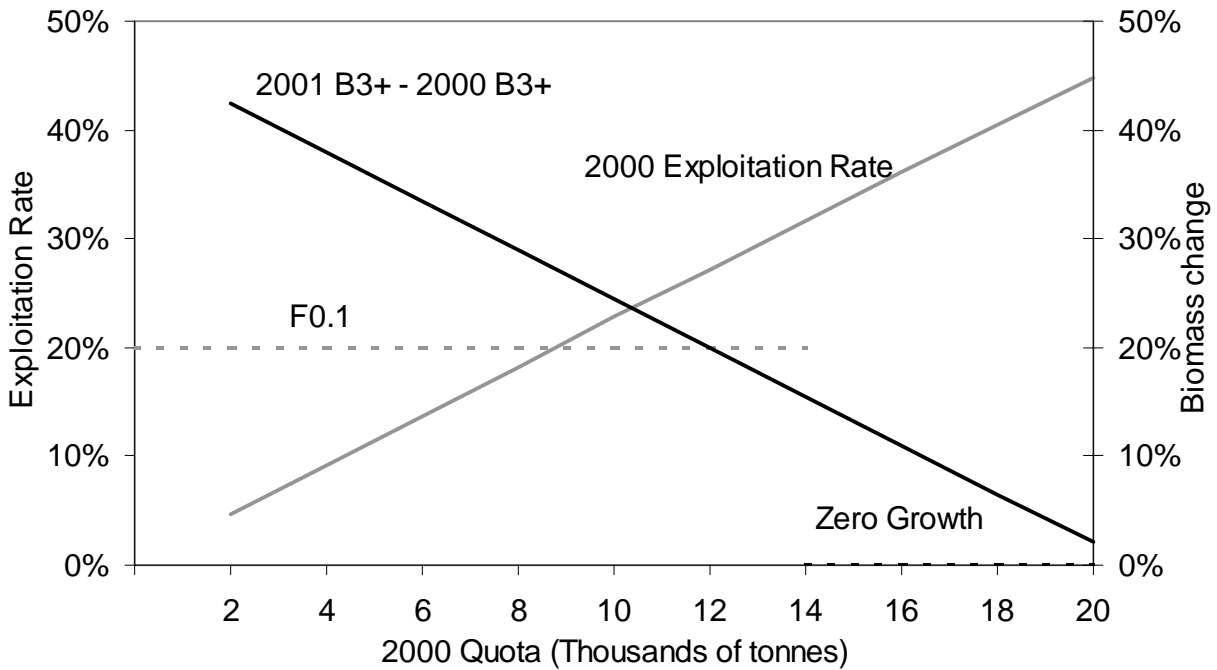

Figure 34. Expected exploitation rate in 2000 and expected change in biomass from 2000 to 2001 for 5Zjm haddock at various quotas.

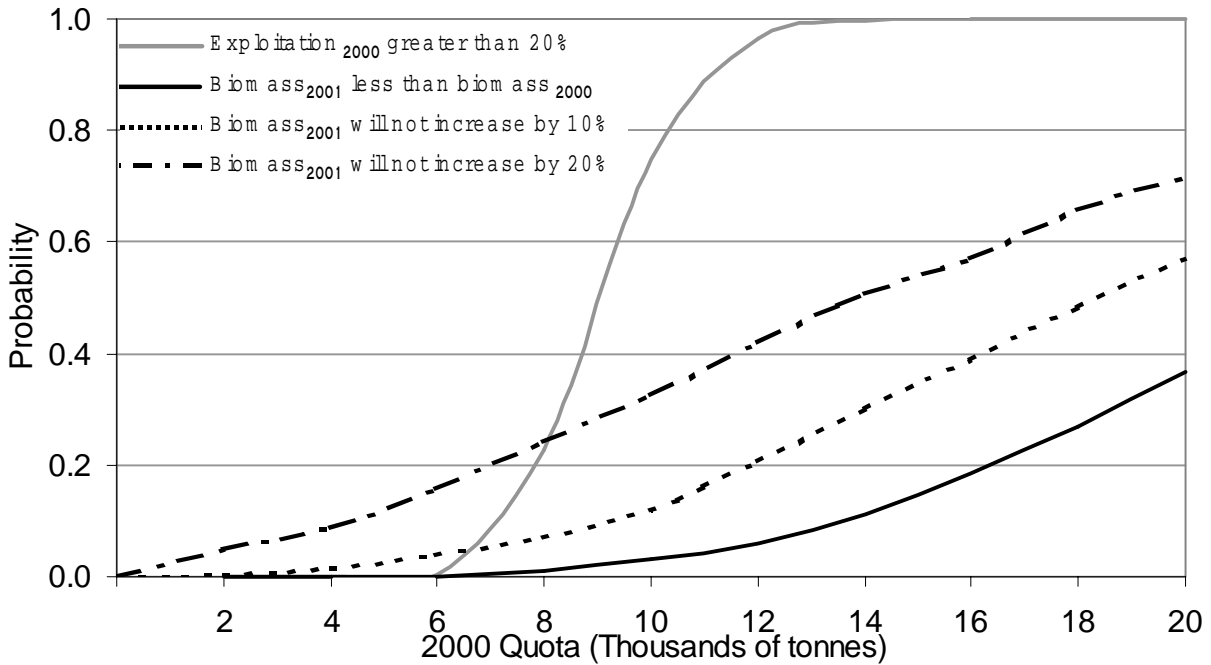

Figure 35. Probability of exploitation rate exceeding 20%, the $F_{0.1}$ reference level, and of the 2001 biomass being less than the 2000 biomass by 0%, 10% and 20% for 5Zjm haddock at various quotas.

Figure 36. Historic catch and biomass of haddock in 5Zjm compared to recent catches and biomass.

Figure 37. Relationship between mature (3+) 5Zjm haddock biomass and recruits at age 1 from 1931 to 1955 and 1969 to 2000.

Figure 38. Ratio of recruits (numbers at age 1) per spawning biomass (kg) suggests that present survivorship appears comparable to that of the 1930s to 1950s.

Appendix A.

Inter and intra-reader agreement tests for L. Van Eeckhaute, the DFO reader, and N. Munroe, the NMFS reader are summarized in Table A1. The agreement matrices are given in Tables A2 to A5. There was evidence of bias in the inter-reader tests (Tables A4 and A5). In both cases the DFO reader was assigning higher ages than the NMFS reader. To try and resolve the discrepancies, annotated images of the otoliths with each readers interpretation were exchanged and the ageing material was also exchanged to determine whether the method of sectioning was causing the differences in interpretation. Results of these exchanges are pending.

Table A1. Summary of ageing tests and results for Georges Bank haddock.

Source	Test	No. of otoliths	% agreement	Comments
N165 1992 DFO Spring Survey	LVE vs LVE	98	99	Check for continuity over time
N871 1999 DFO Spring Survey	LVE vs LVE	98	96	
N871 1999 DFO Spring Survey	LVE vs NM	98	81	Evidence of bias
9804 1998 NMFS Fall Survey	LVE vs NM	50	80	Evidence of bias

Table A2. Inter-reader ageing agreement matrix for L. Van Eeckhaute for haddock ageing material from the 1992 DFO spring survey. This test was designed to ascertain whether a change in interpreting the otoliths had occurred over time.

DFO 1992 Georges Bank Spring Survey (N165)

5				2	4	1	7
6					1	6	7
7						2	2
Total	1	16	11	8	5	9	50

Agreement = $40/50 = 80\%$

Note that there is evidence of bias as the ratio of ages above and below the line of equality is 1:9.

Appendix B.

At the 1999 TRAC, April 20-22, 1999, the assessment team was asked to investigate an apparent inconsistency between survey and fishery weights at age. The text from the TRAC proceedings to describe the problem is reproduced below:

“An inconsistency between the population mean weights at age and the fishery mean weights at age was discussed. It was noted that, in some cases, the mean weight at age in the catch was larger than the population mean weight at age at the beginning of the following year for the same cohort.”

This effect is most apparent when comparing the weight at age values used in the projection (Gavaris and Van Eeckhaute 1999):

Age	1	2	3	4	5	6	7	8
Weight at beginning of year used for population (kg)								
2000	0.13	0.50	0.91	1.25	1.61	2.14	2.52	2.87
Average weight at age for catch (kg)								
1999	0.66	1.11	1.46	1.82	2.24	2.51	3.03	2.95

Except for one instance, the average weight at age of the catch is higher than the population weight at the beginning of the next year. It was thought that this might be due to the difference in which the weights at age are calculated. The survey weights at age are derived from the observed weights while the fishery weights are derived from a length weight equation applied to the lengths. A comparison of the survey and fishery lengths at age was undertaken to determine whether the same trend was seen in the lengths (Fig. B1).

Table B1 follows the lengths at age by year classes. Stronger year classes, which are sampled more reliably than weak, have fewer drops in length from fishery to survey than weak year classes. This effect is more evident before the change in gear in 1993/94. As year classes age, lower population numbers increase this effect. After the switch to larger square mesh gear, drops in length from fishery to survey are frequently observed at the younger ages

The projection for the 1999 fishery was done with weight data for the most recent 4 years to estimate beginning year weights and fishery weights, i.e., 1996 to 1999 for survey data and 1995 to 1998 for fishery data. Fig. B1-A shows the data used in the projection while B shows data previous to the 4 most recent years. The fishery lengths at ages 1, 2, 3 and 4 are higher than the population lengths (survey) the following spring indicating selectivity by the fishing gear and that haddock in this fishery are fully recruited only at age 5 and older. Fig. B1-B shows that haddock were fully recruiting to the fishery by age 3 before 1995. Most of the catch in recent years in the Canadian fishery is mobile gear so this change in partial recruitment is consistent with the change in mobile gear to a larger mesh size and a switch to square mesh from diamond which occurred in 1993/1994.

The length weight equation used to estimate average weight at age for the Canadian fishery is as follows:

$$\text{weight} = .0000158 \times \text{length}^{2.91612}$$

where weight is in kg and length is in cm (Waiwood and Neilson, 1985). This equation is derived from 245 5Ze gutted haddock weights collected by Canadian port samplers from 1982 to 1984 from October to December over the length range of 35 to 79 cm. A conversion factor of 1.2 was used to convert gutted weights to round weights before the length weight relationship was determined. In Fig. B2 survey and fishery weights at age used in the projection are compared to corresponding lengths. The survey weights are estimated from direct observations while the fishery weights are derived from fishery lengths using the relationship described above in which a conversion factor of 1.2 has been used to convert gutted to round weights. This magnifies the gear selectivity effect so that it appears that haddock beyond age 5 are not fully recruited to the fishery.

The USA uses a conversion factor of 1.14 to convert from gutted to round weight while Canada uses 1.2. A comparison of weights derived from length weight equations fitted to round and gutted data was possible using data gathered by Canadian port technicians from 1982 to 1985. Quarter 2 and 3 were available for comparison and conversion factors at length could be calculated for the 2 quarters (Table B2, Fig. B3). They range from 1.17 to 1.19 for quarter 2 and from 1.14 to 1.19 for quarter 3. The majority of the Canadian fishery catch has centered around 53 to 54 cm (for otter trawlers) where the conversion factors are 1.18 and 1.17 respectively. A portion of the Canadian catch is landed as gilled and gutted but it is not reported as such. A conversion factor for this form would be higher than the gutted only factor.

In conclusion, the length analysis is consistent with changes in gear that have taken place in recent times and the seeming inconsistencies are due to selectivity of the commercial bottom trawl gear. The more persistent discrepancies in weights at age between the fishery and survey the following year may be due to problems with the length weight equations and further efforts towards establishing appropriate conversion factors to use to convert from gutted length weight equations to round length weight equations is warranted.

Table B1. Average lengths at age of 5Zjm haddock year classes as observed from the Canadian spring survey and the commercial fishery. Bold type indicates a strong yearclass; shaded values indicate that the weight dropped from the value in the time period before it; the horizontal stepped line denotes the change from diamond mesh to square mesh by bottom trawl gear which occurred gradually in 1993/1994.

Year class	Age 1		Age 2		Age 3		Age 4		Age 5		Age 6		Age 7		Age 8

Fig. B1. Average, median, range and 25 and 75 percentiles of length at age of 5Zjm haddock from surveys and from the commercial fishery. A) Survey data is for 1996 to 1999 and fishery data is for 1995 to 1998. B) Survey data is for 1986 to 1995 and fishery data is for 1985 to 1994.

Fig. B2. Survey and fishery weights at age for 5Zjm haddock used to project beginning of year 2000 population biomass (from survey weights) and yield for the 1999 fishery (from fishery weights) compared to corresponding survey and fishery lengths at age. Survey lengths and weights are the average for 1996 to 1999 and those for the fishery are the average of 1995 to 1998. Fishery weights were calculated from lengths using a weight length relationship (see text) while survey weights are from observed values.

Fig. B3. Conversion factors for 5Zjm haddock from gutted to round derived from length weight equations for quarters 2 and 3. Data was gathered by Canadian port technicians from 1982 to 1985 (see Table 2).
