#### Abstract

Lingcod stocks were examined for the Strait of Georgia, southwest and northwest coasts of Vancouver Island, Queen Charlotte Sound, Hecate Strait and the west coast of the Queen Charlotte Islands. Interpretation of stock condition relies on recent trends in catch statistics and limited age composition data from the commercial trawl fishery.

In the Strait of Georgia (Area 4B), a catch per unit effort index based on creel survey data has increased in recent years, but not to levels that indicate an improvement in stock conditions. A continued strategy for rebuilding of lingcod stocks in Area 4B is recommended.

Off the southwest coast of Vancouver Island (Area 3C), a 25\% Qualified catch per unit effort index (CPUE) based on qualified trawl catches in May-September did not provide evidence for recent changes in abundance. In addition, the age proportion data available for the trawl fishery did not indicate that either a strong cohort or a series of strong cohorts were entering the fishery. We have no new information to revise the existing yield recommendation that total removals do not exceed 1000 tonnes.

Off the northwest coast of Vancouver Island (Area 3D), a 25\% Qualified CPUE based on qualified trawl catches in May-September did not provide evidence for recent changes in abundance. There are no age proportion data to provide information on cohort strength in the fishery. We have no new information to revise the existing yield recommendation of 400-800 tonnes.

In Queen Charlotte Sound (Areas 5A/B), ), a $25 \%$ Qualified CPUE based on qualified trawl catches in May-September did not provide evidence for recent changes in abundance. Age proportion data available for the trawl fishery did not indicate that a either a strong cohort or a series of strong cohorts were entering the fishery. We have no new information to revise the existing yield recommendation of 1100-2200 tonnes. However, it should be noted that this yield range was based on a model that used inaccurate age data and therefore growth and mortality estimates were not well determined.

For the areas in Hecate Strait (Areas 5C/D) and west coast of the Queen Charlotte Islands (Area 5E), there is no new information to revise the existing yield level of 1000 tonnes for all three areas combined.

## Résumé

La présente étude porte sur les stocks de morue-lingue de Georgia Strait, des côtes sud-ouest et nord-ouest de l'île de Vancouver, Queen Charlotte Sound, Hecate Strait et de la côte ouest des îles de la Reine-Charlotte. L'interprétation de l'état des stocks repose sur les récentes tendances des statistiques sur les prises et des données limitées sur la composition des prises selon l'âge issues de la pêche commerciale au chalut.

Dans Georgia Strait (secteur 4B), l'indice des captures par unité d'effort calculé à partir de données de relevé des prises a augmenté dans les dernières années, mais non à des niveaux indiquant une amélioration de l'état des stocks. Une stratégie soutenue de rétablissement des stocks de morue-lingue dans le secteur 4B est recommandée.

Au large de la côte sud-ouest de l'île de Vancouver (secteur 3C), un indice restrictif des captures par unité d'effort (CPUE) de $25 \%$, tiré des prises admissibles au chalut de mai à septembre, n'a pas révélé de changements récents dans l'abondance. En outre, les données sur la composition des prises selon l'âge issues de la pêche au chalut n'indiquent pas qu'une cohorte ou une série de cohortes abondantes sont en voie d'être recrutées à la pêche. Aucun nouveau renseignement n'est disponible pour réviser la recommandation actuelle sur le rendement à l'effet que les prises totales ne dépassent pas 1000 t .

Au large de la côte nord-ouest de l'île de Vancouver (secteur 3D), un indice restrictif des captures par unité d'effort (CPUE) de $25 \%$, tiré des prises admissibles au chalut de mai à septembre, n'a pas révélé de changements récents dans l'abondance. L'absence de données sur la composition des prises selon l'âge ne permet pas d'établir l'abondance des cohortes dans la pêche. Aucun nouveau renseignement n'est disponible pour réviser la recommandation actuelle sur le rendement de 400 à 800 t .

Dans Queen Charlotte Sound (secteurs 5A et B), un indice CPUE restrictif de $25 \%$, tiré des prises admissibles au chalut de mai à septembre, n'a pas révélé de changements récents dans l'abondance. Les données sur la composition des prises selon l'âge issues de la pêche au chalut n'indiquent pas qu'une cohorte ou une série de cohortes abondantes sont en voie d'être recrutées à la pêche. Aucun nouveau renseignement n'est disponible pour réviser la recommandation actuelle sur le rendement de 1100 à 2200 t . On doit toutefois noter que cette gamme de rendement repose sur un modèle fondé sur des données inexactes sur l'âge et que, par conséquent, les estimations de la croissance et de la mortalité ne sont pas précises.

Dans le cas des secteurs de Hecate Strait (secteurs 5C et D) et de la côte ouest des îles de la Reine-Charlotte (secteur 5E), on ne dispose pas de nouveaux renseignements permettant de réviser le niveau de rendement actuel de 1000 t , tous les trois secteurs confondus.

### 1.0 GENERAL INTRODUCTION

We present stock assessments for lingcod throughout British Columbia waters. Tables of lingcod catch for the commercial fisheries, including total landings, qualified catch and effort along with catch per unit effort (CPUE) are updated to the end of the calendar year of 1999. Since sources of information for historical landings vary, we have provided a list of these sources in Appendix I (Table A1). In order to provide a source of information for general lingcod biology and a history of the fishery, separate sections for these topics have been included in this document. In addition, information regarding climate-ocean regimes in the north Pacific has been included to provide a reference section on recent research on decadal-scale dynamics of marine systems. We use information on recent trends in catch statistics, age composition of the commercial catch, creel survey information where appropriate, and consideration of climateocean regimes to provide interpretations of present stock conditions. Pertinent details of lingcod management and quota history have been summarized in Appendix II.

### 2.0 INTRODUCTION TO LINGCOD AND THE FISHERY IN BRITISH COLUMBIA

### 2.1 General Biology

Lingcod (Ophiodon elongatus) are unique to the west coast of North America and occur from Baja, California to the Shumagin Islands, Alaska. They inhabit nearshore waters and are commonly found along the bottom at depths ranging from 3 to 400 m , with most found in rocky areas 10 to 100 m . Lingcod are considered to be a non-migratory species. Tagging studies in the 1980s off the west coast of Vancouver Island indicated that $95 \%$ of the lingcod recovered in the first and second year after tagging tended to be within 10 km of their release site (Cass et al. 1990). Concurrent tagging studies in the Strait of Georgia indicated very little mixing between offshore and inshore stocks (Cass et al. 1990).

Female lingcod mature between ages 3 to 5 years at a mean size of $61-75 \mathrm{~cm}$, while males mature at age 2 at a mean size of 50 cm (Cass et al. 1990). Males can be distinguished externally from females by the presence of a short, broadly conical papilla anterior to the anal opening (Wilby 1937). In Canadian waters, spawning begins in December and continues into March with the peak spawning activity in late January to early February (Wilby 1937; Low and Beamish 1978). Seasonal migration to nearshore spawning sites begins in October, with the males migrating before the females (Cass et al. 1990). Nesting sites are typically in rock crevices or ledges where there are strong currents (Low and Beamish 1978). Lingcod are one of the few marine fishes that exhibit parental care for incubating eggs. The males remain within 1 meter of an egg mass and exhibit aggressive behaviour to larger predators such as kelp greenling (Hexagrammos decagrammus) and striped seaperch (Embiotica lateralis) which typically feed on lingcod eggs and larvae (Low and Beamish 1978). Egg mortality due to predation can be very significant, and nests that are left unguarded, or that have males removed from them, do not survive to hatching (Low and Beamish 1978).

Lingcod begin to hatch in early March through late April, at a length of about 6-10 mm (Phillips and Barraclough 1977). For the first few weeks, the larvae are planktonic and are
found in the upper 3 m of the water column during the day (Phillips an Barraclough 1977), but migrate to deeper waters at night (Cass et al. 1990). By about mid-May the post-larval lingcod are approximately $50-70 \mathrm{~mm}$ and have become demersal, inhabiting areas near kelp or eelgrass beds (Phillips and Barraclough 1977). By September, the young-of-year are found in a wider range of flat bottom areas, and by age 2 begin to inhabit similar substrates as older lingcod (Cass et al. 1990). Typically, larger lingcod inhabit deep banks and reefs, while smaller lingcod inhabit shallow waters and banks (Forrester 1973).

Growth during the first years of life is rapid and up to age 2 it is similar for males and females with both reaching an average length of 45 cm (Cass et al. 1990). After age 2, females grow faster than males, with the growth of males tapering off at about age 8 and females continuing to grow rapidly until about age 12-14. For waters off the west coast of Canada, the maximum age recorded for lingcod was 14 years for males and 20 years for females. Females reach lengths in excess of 100 cm , while males rarely exceed lengths of 90 cm .

As evident from their huge gaping mouths and long, pointed teeth, lingcod are voracious predators. As larvae, lingcod feed on calanoid copepods, decapod larvae, amphipods, euphausiids and larval herring (Clupea harengus) (Phillips and Barraclough 1977). As the young-of-year move inshore and begin a demersal life, their diet switches from zooplankton to juvenile herring (Phillips and Barraclough 1977). Juveniles consume herring, Pacific sand lance (Ammodytes hexapterus), flatfish (Pleuronectidae), shiner perch (Cymatogaster aggregata) and walleye pollock (Theragra chalcogramma) (Phillips and Barraclough 1977; Cass et al. 1990). Some invertebrates such as shrimp (Neomysis macrops) and prawn (Pandalus danae) are consumed (Cass et al. 1990). Adults feed mostly on herring and Pacific hake (Merluccius productus), but are predators of many fish and invertebrates including Pacific sand lance, flatfish, rockfish (Sebastes), spiny dogfish (Squalus acanthias), Pacific cod (Gadus macrocephalus), sablefish (Anoplopoma fimbria), Pacific tomcod (Microgadus proximus), salmon (Oncorhynchus), crabs, shrimps, squid and octopus (Cass et al. 1990). Aside from the early larval stage, lingcod themselves have few predators. The predators of adult lingcod are mainly marine mammals including sea lions and harbour seals (Cass et al. 1990).

### 2.2 History of the Fishery

Commercial fishing for lingcod in British Columbia began around 1860 (Cass et al. 1990). Lingcod catch data has been recorded from a variety of sources since 1927 (Appendix I Table A1). Prior to 1927, lingcod landings were grouped with other groundfish species into a 'cod' category, though there is some suggestion that lingcod comprised almost all of the catch (Ketchen et al. 1983). Between 1900 and the 1940s, lingcod was ranked fourth in commercial importance after salmon, herring and sardines, and was the main source of fresh fish throughout the year (Cass et al. 1990). Prior to the 1940s, the fishery was dominated by the Strait of Georgia hook and line fishery. By the 1940s, most areas off the British Columbia coast were being exploited by the trawl fishery, and since the 1960s, trawl landings have dominated (Appendix I Table A2, Figure 1). In the 1930s and 1940s, hook and line landings ranged from about 2,100 to 4,300 tonnes, but had dropped to less than 200 tonnes by the mid-1950s (Appendix I Table A2, Figure 1). At the same time, trawl landings gradually increased and by the 1950s, averaged over 2,400 tonnes (Appendix I Table A2, Figure 1). In waters off southwestern Vancouver Island (Major Statistical Area 3C, Figure 2), United States trawlers also began to fish lingcod in the

1940s. With the declaration of Canada's 200 mile Canadian Fishing Zone in 1977, US trawl catches in Canadian waters dwindled and had ceased completely by 1980 (Appendix I Table A2).

The commercial lingcod fishery has been subject to a variety of management measures since at least the 1920s (Appendix II Table A3). Since the 1920s, the lingcod fishery has been subject to winter closures in order to protect spawning fish and nest-guarding males. Commercial closures were initially in place from December to February in the Gulf Island region of the Strait of Georgia (Area 4B, Figure 2). In 1979, after further studies into spawning and nest guarding behaviour, this winter closure was extended to November 15 to April 15, and applied to the entire Strait of Georgia. In 1987, winter closures were implemented for all commercial fisheries off the west coast of Vancouver Island. Closures were from January 1 to April 15 in the offshore portions of Areas 3C and 3D and in the west coast Vancouver Island portions of Area 5A, and from November 15 to April 15 in the inshore portions of Areas 3C and 3D. In 1988 the closures were extended to November 15 to April 15 for the entire west coast of Vancouver Island. Since 1942, a coastwide size limit of 58 cm (head-on) on retained lingcod was applied to the commercial fishery. This was extended to 65 cm for Area 4B in 1989, and for the whole coast in 1996. The trawl fishery changed substantially in 1996, with the introduction of onboard vessel observers, bycatch limits for halibut, and the requirement that all catches of quota species, including discards, would be counted against vessel period limits. The winter closure for the trawl fishery was removed in 1996.

The recreational fishery has also been subject to winter closures and size restrictions (Appendix II Table A3; W. Grider, pers. comm. Regulations Unit, Fisheries Management Branch, Fisheries and Oceans Canada, 555 West Hastings Street, Vancouver, BC, V6B 5G3). In 1979, a winter closure (November 15 to April 15) was initiated for the recreational fishery in the Strait of Georgia (Area 4B), and was extended to October 1 to May 31 in 1991. A similar winter closure was initiated for the west coast of Vancouver Island (Areas 3C and 3D) in 1992. In 1991, a size limit of 65 cm was applied to lingcod retained in the Area 4B recreational fishery, and this was extended to the west coast of Vancouver Island (Areas 3C and 3D) in 1999. There is no winter closure or size limit for recreationally caught lingcod in other areas of the coast (Areas 5A to 5E). Presently, there are daily catch limits of 1 for Area 4B and 3 for all other areas, with an annual limit of 10 for Area 4B only.

### 3.0 NORTH PACIFIC CLIMATE-OCEAN REGIMES

Climate-ocean systems of the north Pacific exhibit relative stability on decadalscales, with several possible steady states. Switches between decadal-scale steady states are abrupt, often occurring within one year. The periods of steady states have become known as regimes, while the switches between states are called regime shifts. Regime shifts have been observed in such climate-ocean systems as the Aleutian Low pressure system (Beamish and Bouillon 1993; Beamish et al. 1999); the atmospheric circulation patterns associated with the westerlies (King et al. 1998); Pacific-wide spatial patterns in sea surface temperatures (Mantua et al. 1997); the Arctic atmospheric system (Overland et al. 1999); and the mixed layer depth (Polovina et al. 1994). Within the last 100 years, regime shifts have occurred around 1925 (Minobe 1997), 1947 (Francis and Hare 1994), 1977 (Ebbesmeyer et al. 1991; Beamish and Bouillon 1993) and 1989 (Beamish et al. 1999; Watanabe and Nitta 1999). Presently, there is
suggestion that a regime shift occurred around 1997, manifested in the winter of 1998 (McFarlane et al. 2000; Hare and Mantua 2000).

While the global mechanisms for these north Pacific regime shifts have not been identified, the effects of Pacific basin-wide regime shifts have been observed in regional variables (Ebbesmeyer et al. 1991; Hare and Mantua 2000). Beamish et al. (2000) provide examples for British Columbia regional variables, such as river discharge, atmospheric pressure systems and circulation patterns and coastal sea surface temperatures. More importantly for fisheries science, synchronous shifts have been observed in the productivity patterns of major commercial species such as Pacific salmon (Oncorhynchus spp., - Beamish and Bouillon 1993; Hare and Francis 1995), Pacific sardines (Sardinops sagax, - Kawasaki and Omori 1988), tuna (Thunnus thynnus, - Polovina 1996), Pacific halibut (Hippoglossus stenolepis, - Clark et al. 1999) and sablefish (Anoplopoma fimbria, - King et al. 2000a). Off the west coast of Canada, various pelagic and demersal species have exhibited changes in abundance, recruitment, and distribution that are synchronous with regime shifts (McFarlane et al. 2000). McFarlane et al (2000) noted that key Canadian groundfish species experienced average to above average year class success during the 1977 to 1988 regime. Conversely, year class success tended to be average to below average during the 1989 to 1997 regime. Given the developing evidence for the impact of regime shifts on commercially exploited species, decadal-scale dynamics need to be acknowledged in stock assessment and fisheries management. For the period in which there are catch and effort data for the lingcod fishery (i.e. 1954-1999), regime shifts occurred in 1977 and 1989 with a recent one likely to have occurred in 1998.

### 4.0 INSHORE LINGCOD

### 4.1 Strait of Georgia (Area 4B)

### 4.1.1 Fishery and Management

The commercial fishery for lingcod in the Strait of Georgia began in the mid1800s. A quota was never implemented, but due to conservation concerns, the commercial fishery for lingcod in Area 4B was closed in 1990 and has remained closed, with the exception of portions of Management Areas 12 and 20. Queen Charlotte Strait (Management Subareas 12-7, 12-9, 12-10, 12-13) and Juan de Fuca Strait west of Sheringham Point (Management Subareas 20-1, 20-2, 20-3, 20-4) remain open to both the trawl and hook and line fisheries because populations within these subareas are considered to be part of either the Queen Charlotte Sound (Area 5A, Figure 2) population or the south west coast of Vancouver Island (Area 3C) population (Richards and Yamanaka 1992). Historically, catches in Management Areas 12 and 20 have been reported with Area 4B statistics. A winter closure is in place from November 15 to May 14 for the trawl fishery and November 15 to June 30 for the line fishery in Management Subareas of Statistical Areas 12 and 20.

Historically, lingcod were commercially exploited primarily by the hook and line fishery, but between 1940 and 1990, a small portion of the total landings (about $10 \%$ on average) were from the trawl fishery (Figure 3). Since the commercial closure in 1990, catch is still reported for Area 4B (Figure 3), but this reflects catches in the open subareas in Areas 12 and 20.

Presently, lingcod in Area 4B are exploited by the recreational fishery, and are subject to a size limit of 65 cm (head on) and a winter closure from November 1 to April 30. There is a daily retention limit of 1 , and an annual limit of 10 lingcod caught in the recreational fishery.

### 4.1.2 Catch Statistics

Since the closure of the commercial fishery, the only ongoing source of data for abundance indicators is the Strait of Georgia Creel Survey for the recreational fishery, which has been conducted annually since 1980. The Strait of Georgia Creel Survey covers the majority of area 4B, with the exception Johnstone Strait. Haist (1995) reviewed a number of abundance indices derived from interview data available from the creel survey program. Haist (1995) concluded that significant correlation between recreational fishery based indices and historical commercial catch rates (CPUE) supported the use of recreational fishery data to assess trends in stock abundance. Three recreational fishery indices had high correlations with the commercial CPUE: an index using total lingcod caught and number of fishing trips not directed at lingcod and two indices based on sub-area models. Since all three had similar correlations with the commercial CPUE ( $r=0.86,0.87$ and 0.85 respectively), we have chosen to use only the index based on interview records not directed at lingcod since this information is readily available.

The derivation of the index from interview data is described in Haist (1995). Information on species directed effort is available only since 1984. Since changes in the amount of effort directed to lingcod catches could influence the relationship between catch rates and stock abundance, effort was calculated as the number of interview records (i.e. fishing trips) for which lingcod was not the targeted species (Haist 1995). Catch per record was calculated as total lingcod caught (kept and released) from all interview records divided by the number of fishing trips without directed lingcod effort (Table 1). Since 1984, the catch of lingcod has been decreasing along with the number of interview records without lingcod effort (Table 1). However the catch per record was relatively stable from 1985-1995, with a recent increase in 1996-1999 to levels similar to 1984 (Table 1). The drop in the number of interview records in recent years does not reflect a reduction in sampling effort by the creel survey program, but rather a reduction in the number of recreational fishers (R. Nagtegaal, pers. comm., Stock Assessment Division, Science Branch, Fisheries and Oceans Canada, Pacific Biological Station, Nanaimo, BC, V9R 5K6). Since 1996, the catch per record index has increased to levels that are comparable to values in the mid-1980s. However, it is important to note that the level of abundance for lingcod in the mid-1980s was severely depressed and warranted conservation concerns. Therefore, the recent increase in catch per record index does not indicate that lingcod have reached levels of abundance that do not warrant conservation concerns. In 1991, the number of kept lingcod dropped dramatically in response to the increased size limit implemented that year (Table 1). There was a corresponding increase in the number of lingcod released. Since 1991, the relative number of kept lingcod has remained fairly constant, indicating that there has not been an increased availability of lingcod greater than 65 cm .

The Strait of Georgia creel survey program provides expanded catch estimates for targeted species based on interview data and aerial surveys. In 1999 (April-October inclusive), the estimated number of retained lingcod in the Strait of Georgia recreational fishery was 3,601 pieces (L. Nagy, pers. comm., Stock Assessment Division, Science Branch, Fisheries and Oceans Canada, 555 West Hastings Street, Vancouver, British Columbia, V6B 5G3). As noted
earlier, this creel estimate is for the majority of area 4B with the exception of Johnstone Strait. Recreational catches are monitored in Johnstone Strait by the North Vancouver Island Creel Survey program. For 1999 (July-September inclusive), the estimated catch for retained lingcod in Johnstone Strait was 2,056 pieces (J. Sturhahn, pers. comm., Stock Assessment Division, Science Branch, Fisheries and Oceans Canada, Pacific Biological Station, Nanaimo, BC, V9R 5K6). Mean lengths are available for lingcod caught in Johnstone Strait only. In 1999, the mean length of lingcod was 80.8 cm (stdev=12.66; $\mathrm{n}=118$ ). Using research survey length and weight data in Cass et al. (1990, Appendix Table 7), a length-weight relationship for lingcod (19771985) is given by

$$
\ln W_{\mathrm{kg}}=3.3287 * \ln \left(\mathrm{~L}_{\mathrm{cm}}\right)-12.94 .
$$

Applying 80.8 cm to this equation, the mean weight of a lingcod retained by the recreational fishery is approximately 5.4 kg . An estimate for the catch (tonnes) of lingcod in the recreational fishery in Area 4B is 30.5 tonnes. This represents a minimum estimate since the creel survey in Johnstone Strait does not cover the complete fishing season (May-October), though it is likely that the catch for the full season was less than 35 tonnes.

### 4.1.3 Climate-ocean regime considerations

The 1989 regime shift has been associated with changes in the Strait of Georgia ecosystem, most notably changes in Fraser River discharge (Beamish and McFarlane 1999). Corresponding shifts in dominant fish species have also been noted, and include increases in the abundance of Pacific hake and herring, along with substantial declines in coho marine survival. Some species such as Pacific cod, English sole and inshore rockfishes are at low abundance levels (Beamish and McFarlane 1999). Given observations regarding poor recruitment for many marine species during the 1989-1997 regime (McFarlane et al. 2000), rebuilding of the Strait of Georgia lingcod stocks during the 1990s might be expected to be slow.

### 4.1.4 Condition of the stock

While the recreational catch per record index indicates some improvement in lingcod abundance in recent years, recreational restrictions in salmon fishing may have limited the ability of this index to detect abundance trends. Given changes in the Strait of Georgia ecosystem that have been reported to coincide with the 1989 regime shift, lingcod might not have experienced strong year classes in the 1990s. Therefore, while the index has increased in recent years, abundance likely remains at levels which warrant conservation concern. There is no biological information to identify any current strong year classes, if present. However, in the upcoming spawning season, we plan to conduct nest density surveys. The results will be compared to similar surveys conducted in the late-1970s and early-1990s, in the hopes that these surveys will provide an additional, and independent, index of relative abundance.

### 4.1.5 Yield Options

The previous stock assessment for inshore lingcod (Beamish et al. 1995) recommended that the commercial fishery closure should be maintained and the current sport
fishing regulations should continue. Winter closure and size limit regulations should remain in place in the open portions of Management Areas 12 and 20.

Yield options remain unchanged from previous assessments.

### 5.0 OFFSHORE LINGCOD

### 5.1 Southwest Coast Vancouver Island (Area 3C)

### 5.1.1 Fishery and Management

Lingcod stocks off the southwest coast of Vancouver Island are exploited primarily by the trawl fishery, but also by hook and line and recreational fisheries. Since the 1940s, a size limit has been in place for all commercial fisheries. Initially, that limit was 58 cm (head-on) and the size was increased to 65 cm in 1996. In 1987, a winter closure (January 1 to April 30) was initiated for all commercial fisheries and in 1988 the period was extended to November 15 to April 15. In 1996, the winter closure for the trawl fishery was removed as a reflection of separate quota allocations for the trawl fishery and the hook and line fishery. The winter closure was initiated to protect males that guard nests and these were presumed to be unavailable to the trawl fishery since the males are typically on inshore reefs. In 1992, a winter closure (November 15-April 15) was initiated for the recreational fishery and a size limit of 65 cm was introduced in 1999. The first lingcod quota assigned to Area 3C was 1400 t in 1987 (B. Ackerman, pers. comm. Groundfish Unit, Fisheries Management Branch, Fisheries and Oceans Canada, 555 West Hastings Street, Vancouver, BC, V6B 5G3). The quota was increased to 2000 $t$ in 1991, and 2100 t in 1993. The quota was reduced in 1996 to 1540 t and reduced again in 1997 to 1400 t of which 1225 t was allocated to the trawl fishery and 275 t to the line fishery. In 1998, the quota was further reduced to 950 t with 800 t allocated to the trawl fishery and 150 t to the line fishery.

For the 1999-2000 fishing year, a 65 cm size limit was in place for all lingcod retained in the commercial and recreational fisheries. The hook and line and recreational fisheries in Area 3C were subject to a winter closure from November 15 to April 15. The quota allocations remained at 800 t for the trawl fishery and 150 t for the hook and line fishery.

### 5.1.2 Catch Statistics

Since the 1950s, the trawl catch has accounted for the majority of lingcod landings in Area 3C (Table 2, Figure 3). American trawlers were active in Area 3C until the declaration of the Canadian Fishing Zone in 1977. However, US trawl catch was not recorded until 1954. During the 1950s and 1960s, the US trawl catch was at least equal to the Canadian trawl catch, but on average was 1.5 times larger. By the 1970s, the US trawl catch was approximately one third of the Canadian trawl catch and 1980 was the last year that American trawlers caught lingcod in Area 3C. The total trawl catch has varied between approximately 250 to 3400 t (Table 2). Line catch of lingcod dominated the total catch in Area 3C until the mid-1950s. The hook and line catch has been about one fifth that of the total trawl catch since the mid-1950s, and has varied from approximately 80 to 295 t (Table 2). Total catch of lingcod has ranged from 30 t to

3600 t (Table 2). Since the initiation of a quota in Area 3C in 1987, the total catch of lingcod has averaged approximately $62 \%$ of the total quota allocated for a fishing year.

Cass et al. (1988) outlined the selection of commercial catch data for compilation of catch per unit effort (CPUE) to use as lingcod abundance indices. Only landings of trawl vessels using double gear (i.e. gear suspended from a double cable) are used since they represent the majority of lingcod landings since the 1950s. Trawl catch records for 1954-1995 are from two sources (Rutherford 1999). Source 1 records, often designated "interviewed" records, consist of trip reports prepared by port liaison officers, based on fisher log books and supplemented by information obtained from observations during unloading of vessels, from sales slips, and from dockside monitoring records. Source 2 records are sales slips or landing records only and were not verified by a port observer. Both sources can provide estimates of total lingcod catch, but only the Source 1 records have associated effort data and are therefore suitable for use in constructing a CPUE index. Since 1996, Fisheries Observers have been on board all trawl vessels during fishing operations, and therefore all landings since 1996 are accompanied by a detailed trip report which includes effort data. Cass et al. (1990) suggested that only those landings which occurred during May-September should be used, as the trawl fishery is highly seasonal. Between 1954-1999, 84\% of the Canadian lingcod catch occurred during MaySeptember. Selecting landings from this time period also reduces any temporal bias introduced by the unavailability of male lingcod to the trawl fishery during the nesting season in OctoberApril. In addition, they suggested that the most appropriate CPUE was based on the catch and effort from landings in which the lingcod catch accounted for $25 \%$ or more of the catch by weight ( $25 \%$ Qualified CPUE). Richards and Hand (1991) used a $25 \%$ CPUE index where effort was standardised for horsepower. However, Richards and Yamanaka (1992) examined differences between low and high horsepower CPUE indices and noted that they were similar since 1970. All subsequent lingcod stock assessments have used the $25 \%$ Qualified trawl CPUE (MaySeptember) without standardised effort for horsepower as an indicator of lingcod abundance trends.

During the 1990s, total 3C trawl catch has declined from approximately 1200 tonnes in 1990-1991 to 250 t in 1999 (Table 2). The declining catch was accompanied by a declining $25 \%$ Qualified effort (Table 3, Figure 3). The $25 \%$ Qualified CPUE has also been decreasing in the 1990s, with two exceptions in 1993 and 1998. In 1993, there was an increase in trawl catch of lingcod, and a decline in the $25 \%$ Qualified effort. These were associated with a sharp increase in $25 \%$ Qualified CPUE (Figure 3 ). There was also an increase in $25 \%$ Qualified CPUE in 1998, but it was not accompanied by an increase in total trawl catch and may reflect high landings from a few fishing trips.

Recently, industry members have raised concern regarding the allocation of catch to statistical areas. We assign catch from any tow to a single statistical area based on the midpoint of the start and end points of the tow, even though the catch may occur at any point during the tow, and the tow may not be in a straight line. Industry members suggested that in Areas 3C and 3D, fishing tows are often started in one statistical area but end in the other, or start and end in one area, but "loop" into the other area for the majority of the tow. Analysis of individual tows conducted in 1996-1999 where the start or end point of the tow was in Area 3C indicates that between $0.1 \%$ and $16 \%$ of the total trawl catch assigned to Area 3C in these years was from tows that started in one area and ended in the other. Analysis of individual tows conducted in

1996-1999 where the mid-point of the tow was within 3 n.mi. of the border between Areas 3C and 3D indicated that between $1 \%$ and $7 \%$ of the total trawl catch assigned to Area 3C was from tows which may have "looped" into Area 3D. Both types of tows contributed to less than $1 \%$ of the $25 \%$ Qualified catch in either area for 1996-1999. Therefore, concern regarding allocation of catch to area is not likely paramount, and we continue to use the mid-point of trawl tows to designate lingcod catch to statistical area.

It is important to note that the proportion of the total trawl catch that qualified for the May through September level dropped substantially in 1996-1998. This does not reflect a decrease in the number of landings with $25 \%$ of the catch comprised of lingcod. Rather, it reflects a decrease in all catches of lingcod in May through September. As mentioned previously, the lingcod catch in May through September generally represents $84 \%$ of the total annual lingcod trawl catch. However, in 1996, 1997 and 1998, the lingcod catches in May through September were only $17 \%, 9 \%$ and $9 \%$ of the annual trawl catch for lingcod. In 1999, this proportion increased to $46 \%$. The monthly lingcod catches for 1996-1998 were highest in December through February (Figure 4). For each of these time periods, the average number of trawl landings were 34 and the average landing of lingcod was 9.2 t , indicating winter catch was not limited to a few large landings. Biological samples ( $\mathrm{n}=161$ ) collected during winter months for these years were almost entirely female ( $99 \%$ ). The dominant age of females ( $\mathrm{n}=159$ ) was 7 and the mean length was 80 cm . Sex ratio bias in catch can have implications on future recruitment. Trawl targeting on lingcod during winter months may have implications recruitment for the 1996-1998 year classes, since the catch was predominantly female.

The recreational fishery in and around Barkley Sound has been monitored by a creel survey program since 1984. Seasonal coverage of the creel survey has varied, with interviews conducted June through September in some years (1987, 1997, 1998 and 1999) and interviews conducted July through September since 1989. Only August and September have been continuously covered by the creel survey since 1984. Estimates of lingcod caught (kept and released) in August and September range from 259 pieces (in 1986) to 5849 pieces (in 1989) (Table 4).

Previous stock assessments have used the catch (kg) per unit effort (10 boat trips) as an index of abundance for lingcod around the Barkley Sound and Alberni inlet. These estimates were based on a mean weight of 1.6 kg . However, there are no biological data available for the recreational fishery to evaluate the appropriateness of this mean weight. Given an increase in the size limit, this mean weight is likely no longer applicable. We report on pieces per unit effort ( 10 boat trips) since it is not confounded with the difficulties of estimating mean weight (Table 4). The CPUE index has a high catch per unit effort in the late-1980s, lower rates from 1990-1995, and a return to higher rates in 1996, 1997 and 1998. The catch per unit effort in 1999 dropped drastically. This may reflect changes in angler behaviour given the restrictions to salmon fishing; however, it is important to note that fishing effort in 1999 remained high. The drastic drop in estimated lingcod catch more likely reflects the increase in legal size limit implemented in 1999.

### 5.1.3 Size and age composition of commercial landings

Biological sampling has been conducted on landed commercial catch from the lingcod trawl fishery in Area 3C since 1977. Samples provide data on length, sex, and where ageing structures are collected, age is determined by the fin-ray method (Chilton and Beamish 1982). In the early 1990s, age determination of lingcod was of questionable quality and it was determined that criteria used in the methodology had changed (McFarlane and Leaman 1993). As a consequence, several years of biological samples were re-estimated for individual ages using correct criteria. A number of additional samples collected between 1983 and 1988 have not yet been re-aged, and are therefore not included in this assessment. The fin-ray methodology for age determination of lingcod has since been validated (McFarlane and King 2000). For Area 3C, on average about 3 samples were collected each year ranging between 1 and 9. The average number of fish per sample was 280, with a range from 50 to 977 . Ages are determined for all suitable samples, but for some large samples, age determination is done for a random subsample of age structures.

Catch curves for combined age frequency data for 1977-1999 illustrate that lingcod begin to recruit at age 2 (Figure 5). Full recruitment for males is at age 5, while that for females is at age 6 (Figure 5). We therefore use relative high proportions of age 4 lingcod to identify potential strong year classes. Annual age composition was plotted as an age proportion bubble plot (Figure 6). The plot was created using S-Plus code (Mathsoft 2000) provided by R. Haigh (Pers. Comm., Stock Assessment Division, Science Branch, Fisheries and Oceans Canada, Pacific Biological Station, Nanaimo, BC, V9R 5K6). The 1985 year class ins the most dominant year class evident in the bubble plot (Figure 6). The year class first appeared as 4 year olds in the 1989 fishery, followed through as 5, 6, 7 and 8 year olds in the 1990-1993 fisheries. In addition, the 1989-1991 year classes also appeared to be of moderate strength, though sample sizes in the 1993, 1994 and 1996 fisheries were small ( $\mathrm{n}=100,50$ and 63) and might not be sufficient to represent the relative proportion of these year classes.

An increase in mean size (cm) for males accompanied the increase in the size limit that occurred in 1996 (Figure 7). There was no evidence of a long-term trend in size for either sex prior to 1996.

### 5.1.4 Climate-Ocean Regime Considerations

Many groundfish species exhibited above average year class strength during the 1977-1988 regime (McFarlane et al. 2000). Lingcod year classes appeared to be of at least moderate strength during this period. Several aspects of the west coast Vancouver Island ecosystem changed with the 1989 regime shift, and include zooplankton composition, upwelling and downwelling intensity (King et al. 2000b). King et al. (2000a) noted that sablefish year class strength declined abruptly after the 1989 regime shift. McFarlane et al. (2000) noted that several groundfish species exhibited below average year class strength after 1989. Lingcod year classes do not appear to be strong or persistent in the fishery after 1989 (Figure 6).

### 5.1.5 Condition of the stock

The 25 \% Qualified CPUE has remained at a consistent level during the late 1990s. The $25 \%$ Qualified CPUE did increase dramatically in 1998, though this was accompanied by a low level of effort. The recreational fishery catch per unit effort (pieces/hour) also increased in 1998. However, both commercial 25\% Qualified CPUE and recreational CPUE decreased in 1999. At present there does not appear to be any indication of large, persistent changes in lingcod abundance in Area 3C. Age composition data indicate the 1985 year class was strong and supported the fishery into the early 1990s. However, there is no indication that other year classes have been as strong in the 1990s. The switch in fishery behaviour in 1996-1998 noted above may negatively impact recruitment of the 2001-2003 fisheries and should be monitored in future stock assessments.

### 5.1.6 Yield Recommendations

The current quota of 950 tonnes was initiated in 1998 (Appendix II Table A4). The previous stock assessment (Leaman and McFarlane 1997) recommended that the total removals not exceed the 1000 t level. In addition, they recommended a conservative harvesting approach until there is indication that the stock has initiated either a very strong cohort or a series of stronger cohorts.

We have no new information to alter previous advice. We therefore recommend that the total removals do not exceed 1000 t . All existing commercial and recreational fishing regulations should remain in place.

### 5.2 Northwest Coast Vancouver Island (Area 3D)

### 5.2.1 Fishery and Management

Lingcod off the northwest coast of Vancouver Island (Area 3D, Figure 2) are exploited primarily by the trawl fishery, but also by the hook and line and recreational fisheries. As early as the 1940s, a size limit of 58 cm (head-on) was applied to all commercial lingcod fisheries. In 1987, a winter closure (Jan. 1 - April 30) was applied to the commercial fishery in order to protect spawning fish and nest guarding males. The following year this closure was extended to Nov. 15 - April 15. In 1992, a similar winter closure was implemented for the recreational fishery in Area 3D (W. Grider, pers. comm.). A quota of 600 t was implemented for Area 3D in 1993, and applied to both the trawl and hook and line fisheries (B. Ackerman, pers. comm.). In 1996 the 58 cm commercial size limit was increased to 65 cm (head-on), and the combined trawl and line quota was increased to 660 t (B. Ackerman, pers. comm.). In addition, the trawl fishery for lingcod in Area 3D was affected by the same management changes in 1996 as noted for Area 3C, regarding quarterly trip limits, observers, and bycatch reduction measures and the removal of a winter closure. In 1997, the quota was reduced to 400 t , of which 220 t was allocated to the trawl fishery, and 180 t was allocated to the hook and line fishery (B. Ackerman, pers. comm.). In 1999, a size limit of 65 cm (head-on) was applied to the recreational fishery in Area 3D for the first time.

For the 1999-2000 fishing year, a 65 cm (head-on) size limit was in place for all lingcod retained in the commercial and recreational fisheries. Winter closures applied to the commercial hook and line and recreational fisheries from Nov. 15 - April 15. Quotas of 220 t and 180 t were allocated to trawl and hook and line fisheries, respectively. A daily limit of 3 pieces applied to the recreational fishery.

### 5.2.2 Catch Statistics

Commercial catch statistics, including 25\% Qualified catch, effort, and catch per unit effort (CPUE) for Area 3D were compiled in the same manner as for Area 3C (Table 5 and Table 6). Total catch in Area 3D has ranged from less than 100 t in the 1920s-1940s to a high of 1400 t in 1994 (Table 5, Figure 3). Catches were largely dominated by the trawl fishery from about 1961 - 1996, but in recent years (1997-1998) line catches have exceeded trawl catches.

American trawlers were active in Area 3D until the declaration of the Canadian Fishing Zone in 1977. However, US trawl catch was not recorded until 1954. During 19541963, total trawl catch averaged 137 tonnes per year, of which about $60 \%$ was caught by US trawlers (Table 5). In 1964-1972, Canadian trawl catch increased dramatically, due to dramatic increase in effort (Table 6, Figure 3). Total catch peaked at 976 t in 1968, of which 719 t was caught by Canadian trawlers. US trawl catch remained at similar levels to the previous decade, but now averaged only $17 \%$ of the total trawl catch. Between 1973 and 1977, total trawl catch was around 233 tonnes per year, with Canadian and US trawlers each contributing about $50 \%$ of the total catch. The last recorded catch by US trawlers in Area 3D was in 1981.

The $25 \%$ Qualified catch has typically represented about $70 \%$ of the total trawl landings. However, in the 1990s, this proportion dropped to approximately $40 \%$. The $25 \%$ Qualified catch and effort peaked in 1994 at 581 t and 2033 h , contributing significantly to the historic high of 1400 t total catch (Table 5 and Table 6, Figure 3). However, the $25 \%$ Qualified CPUE was $286 \mathrm{~kg} / \mathrm{h}$ in 1994, approximately equal to the long term (1954-1999) median CPUE of $291 \mathrm{~kg} / \mathrm{h}$. The $25 \%$ Qualified catch, effort, and CPUE declined substantially in 1995, although levels were quite similar to those in the early 1990s, and may reflect that effort levels in 1994 were unusually high. Significant management changes introduced in 1996 have changed the behaviour of the trawl fleet, and may have resulted in reduced targeting on lingcod. As a result, $25 \%$ Qualified catch and effort have declined sharply, and in 1997-1999 ranged from 16 - 34 t , and from $64-108 \mathrm{~h}$, respectively. Total trawl catch in these years ranged from 83-106 t. The $25 \%$ Qualified CPUE was $263 \mathrm{~kg} / \mathrm{h}$ in 1997, but increased to over $300 \mathrm{~kg} / \mathrm{h}$ in 1998 and 1999.

The proportion of the interviewed trawl catch that meets qualification levels is the lowest in the time series for the period 1997-1999. This is due largely to a dramatic drop in MaySeptember trawl catch (Figure 4). However, unlike Area 3C, this change in summer lingcod landings was not accompanied by a large increase in winter landings (Figure 4).

Line catch of lingcod in Area 3D began increasing in 1985, rising from 194 t in 1985 to 673 t in 1993, but dropping to 182 t by 1996 (Table 5, Figure 3). Over this time period, line catch accounted for an average of around $45 \%$ of the total catch in Area 3D. In 1997, 1998, and 1999 line catch increased to 230, 258 and 206 t respectively, accounting for around $67 \%$ of the total catch. Most of the lingcod caught by hook and line in Area 3D is incidental to the
rockfish hook and line fishery, but recent increases in line catches are due to increased targeting on lingcod (Leaman and McFarlane 1997). The substantial reduction in effort in the trawl fishery may have resulted in increased opportunities for hook and line vessels to target lingcod.

### 5.2.3 Size and age composition of commercial landings

Biological sampling has been conducted on landed commercial catch from the lingcod trawl fishery in Area 3D since 1979. One to three samples were collected intermittently from 1979-1999. The average number of fish per sample was 100, with a range from 50 to 210. Ages are usually determined for a proportion of the suitable samples, as time and budgetary constraints permit.

Catch curves from combined age frequency data for 1979-1999 are much noisier than those for Areas 3 C and $5 \mathrm{~A} / \mathrm{B}$, most likely due to the limited number of years for which samples are available, and may not reflect the overall catch composition. However, it is most likely that the catch composition for Area 3D is similar to Areas 3 C and $5 \mathrm{~A} / \mathrm{B}$, and that the age of full recruitment is around age 5. The age composition structure available from bubble plots (Figure 6), can not be interpreted for strong and persistent year classes in the fishery since many consecutive years are missing.

There was no detectable increase in the mean size of males or females after the size limit increase in 1996 (Figure 7).

### 5.2.4 Climate-Ocean Regime Considerations

Many groundfish species exhibited above average year class strength during the 1977-1988 regime (McFarlane et al. 2000). Several aspects of the west coast Vancouver Island ecosystem changed with the 1989 regime shift, and include zooplankton composition, upwelling and downwelling intensity (King et al. 2000b). King et al. (2000a) noted that sablefish year class strength declined abruptly after the 1989 regime shift. McFarlane et al. (2000) noted that several groundfish species exhibited below average year class strength after 1989. While lingcod year class strength information is not available for Area 3D, it is likely that year classes in the 1990s were not strong.

### 5.2.5 Condition of the stock

Stock abundance in Area 3D shows no evidence of a decline based on the $25 \%$ Qualified CPUE for recent years. However, we caution that the changes in management which occurred in 1996 have significantly changed the lingcod fishery, resulting in substantially reduced effort in the trawl fishery, accompanied by a rise in targeted effort in the hook and line fishery, thereby eroding the reliability of the $25 \%$ Qualified trawl CPUE as a relative abundance index for this area. In addition, we have little biological information with which to assess year class strength.

Recommended low to high risk sustainable yield options were set to 400-800 t in Area 3D in the 1991 stock assessment (Appendix II Table A4; Richards and Yamanaka, 1992). These yield options were based on an estimated sustainable yield of $600 t$, determined from the mean of the group of historical catches that were greater than the long term mean of 400 t (Richards and Hand, 1991). The previous stock assessment (Leaman and McFarlane 1997) did not recommend changes to the existing quota recommendations. However they did recommend that managers consider a low risk approach to harvest for this stock.

We have no new information to revise the existing quota recommendation. We recommend the continuation of existing commercial and recreational regulations.

### 5.3 Queen Charlotte Sound (Areas 5A and 5B)

### 5.3.1 Fishery and Management

Lingcod stocks in Queen Charlotte Sound (Areas 5A and 5B, Figure 2) are primarily exploited by the trawl fishery, although lingcod is a minor component of the total trawl fishery. There are also small catches by the hook and line fishery.

A size limit of 58 cm (head-on) originally applied to these areas, but was increased to 65 cm (head-on) in 1996. In 1987, a winter closure of January 1 to April 15 was initiated for all commercial fisheries in portions of Area 5A. This period was extended to November 15 to April 30 in 1988. The trawl winter closure was removed in 1996. In 1999, a specific winter closure was not specified for the line fishery in Area 5A, rather the fishery was opened from April 15 until the total allowable catch was obtained. A quota of 1650 t was implemented in 1993 and applied to both the trawl and the hook and line fisheries. The combined quota was increased to 1815 t in 1996. In 1997, the quota was reduced to 1100 t , of which 862 t and 238 t were allocated to the trawl and hook and line fisheries, respectively. In 1998, the allocations were changed slightly, to 900 t and 200 t , respectively. In 1999, the trawl quota was reduced to 862 t , but the hook and line allocation specified 125 t for Area 5A and 75 t for Area 5B (200 t in total). The trawl fishery for lingcod in Areas 5A and 5B was affected by the same management changes in 1996 as noted for Area 3C, regarding quarterly trip limits, observers, and bycatch reduction measures.

For the 1999-2000 fishing year, a 65 cm (head-on) size limit was in place for all lingcod retained in the commercial fisheries. There was no size limit for lingcod retained in the recreational fishery. The quota allocations remained at 862 t for the trawl fishery in Areas 5A and 5B combined, and 125 t and 75 t for the hook and line fishery in Area 5A and Area 5B, respectively. A daily limit of 3 pieces applied to the recreational fishery.

### 5.3.2 Catch Statistics

Commercial catch statistics, including 25\% Qualified catch, effort, and catch per unit effort (CPUE) for Areas 5A and 5B were compiled in the same manner as for Area 3C (Table 7 and Table 8). Total catch has ranged from less than 100 t prior to the 1940s, to historic
highs of around 2300 t in 1968 and 1990 (Table 7, Figure 3). Catches have been dominated by the trawl fishery since the 1950s. American trawlers were active in Areas 5A and 5B until the declaration of the Canadian Fishing Zone in 1977. However, US trawl catch was not recorded until 1954. US trawl catch averaged around $60 \%$ of the total trawl catch for the duration of the US fishery in Queen Charlotte Sound (Table 7). The last recorded catch by US trawlers in Areas 5A and 5B was in 1980. Hook and line catch has increased since 1987, rising to a high of 305 t in 1991, and falling to 262 t in 1992 (Table 7, Figure 3). Line catches in 1993-1999 have averaged about $154 \mathrm{t} /$ year.

The $25 \%$ Qualified catch has historically represented about $65 \%$ of the total trawl catch. There have not been any recent declines in this proportion in recent years as were observed in other areas. The $25 \%$ Qualified effort increased dramatically from an average of around 700 h in the 1970 s to 2039 h in 1981 (Table 8, Figure 3). The $25 \%$ Qualified effort averaged around 3100 h in 1981-1995. In contrast, the $25 \%$ Qualified CPUE peaked in 1986 at $433 \mathrm{~kg} / \mathrm{h}$, and has declined steadily. In 1995, CPUE was only $168 \mathrm{~kg} / \mathrm{h}$, much smaller than the long term (1951-1999) median and average of $245 \mathrm{~kg} / \mathrm{h}$ and $249 \mathrm{~kg} / \mathrm{h}$, and one of the smallest CPUE values in the time series. Following the management changes in 1996, total trawl catch decreased by about $50 \%$ from $1239-633 \mathrm{t}$, while the $25 \%$ Qualified effort decreased by about $60 \%$ from $5412-2362 \mathrm{~h}$. At the same time, CPUE increased from $168-196 \mathrm{~kg} / \mathrm{h}$. In 1997, catch and effort again declined, but CPUE increased to $217 \mathrm{~kg} / \mathrm{h}$. Since 1997, total trawl catch has risen from 386 - 533 t , and effort from 1082 - 2167 h , while CPUE has declined from 217 $173 \mathrm{~kg} / \mathrm{h}$.

### 5.3.3 Size and age composition of commercial landings

Biological sampling has been conducted on landed commercial catch from the lingcod trawl fishery in Areas 5A and 5B since 1977. On average, about 3 samples per year are collected, although the number of samples ranges between 1 and 6 . The average number of fish per sample was 168 , with a range from 50 to 382 . Ages are usually determined for a proportion of the suitable samples, as time and budgetary constraints permit. As for Area 3C, ages were estimated during the early 1990's using incorrect aging criteria. Of the affected samples, only those where ages have been re-estimated using correct criteria have been included in this assessment. A number of samples which were collected between 1981 and 1990 have yet to be re-aged and are therefore not included. As for Area 3C, some large samples are subsampled prior to age determination.

Catch curves from combined age frequency data (1977-1999) reveal that the age of full recruitment for males is 5 and that for females is 6 (Figure 5). The 1985 year class appears as a dominant and persistent year class in the fishery from 1989-1993, as ages 4-8 (Figure 6). The year classes 1976-1978 appear to be of comparable strength to the 1985 year class in the few years where samples are available (1981 and 1983), but due to the lack of samples in subsequent years it is impossible to evaluate the persistence of these year classes. As with Area 3C, the 1990 and 1991 year classes appeared in the 1994 and 1995 fisheries as moderate proportions at age 4. However, these year classes did not appear to dominant the fishery in subsequent years. The 1993 year class was prominent in the 1997 fishery sample as 4 year olds, though the sample size is probably too small $(\mathrm{n}=50)$ to be representative of relative proportions-at-age. In addition, the 1994 year class was prominent in the 1999 fishery sample ( $\mathrm{n}=250$ ) as 5 year olds.

There was no change in the mean size of males or females following the increase in size limit in 1996 (Figure 7). In fact, the mean size of males in 1996 was below the size limit of 65 cm .

### 5.3.4 Climate-ocean regime considerations

At present, we do not have ecosystem information for Queen Charlotte Sound. The regime shifts of 1977 and 1989 that produced abrupt changes in the Strait of Georgia and the west coast Vancouver Island ecosystems will have also had consequences for the Queen Charlotte Sound ecosystem, since those regime shifts were observed in basin-wide north Pacific climate-ocean systems.

### 5.3.5 Condition of the stock

Though the 25\% Qualified CPUE for lingcod stocks in Areas 5A and 5B has been declining since the late 1980s, it has remained fairly constant since 1992. There is some indication that the 1993 year class was of at least moderate strength.

### 5.3.6 Yield recommendations

Recommended low to high risk yield options have been suggested as 1100-2200 t in Areas 5A/5B (Appendix II Table A4; Richards and Yamanaka, 1992). These yield options were based on equilibrium fishing model analyses (Schnute et al. 1989) and consideration of the productivity off the west coast of Vancouver Island. However, model results should be considered with some caution, as the growth and mortality estimates used were not well defined (Richards and Yamanaka 1992), and examination of the ageing data created additional uncertainty (McFarlane and Leaman, 1995). Quotas were set 1100 t in 1996, and have remained at that level.

The previous stock assessment (Leaman and McFarlane 1997) recommended low and high risk yield options of 1100 and 2200 t . However, they recommended the low risk approach to harvest for this stock.

We have no new information to revise the existing quota recommendation. We recommend the continuation of existing commercial and recreational regulations.

### 5.4 Hecate Strait (Areas 5C and 5D) and West Coast Queen Charlotte Islands (Area 5E)

### 5.4.1 Fishery and Management

Lingcod in Hecate Strait (Areas 5C and 5D, Figure 2) and off the west coast of the Queen Charlotte Islands (Area 5E, Figure 2) are a minor component of both the trawl and hook and line fishery. However, hook and line landings have accounted for an increasing proportion of the total catch, and in recent years, the directed line fishery for lingcod has also increased.

A size limit of 58 cm (head-on) originally applied to these areas, but was increased to 65 cm (head-on) in 1996. No winter closures have been applied to date. A quota of 1000 t was implemented in 1993 and applied to both the trawl and hook and line fisheries in

Areas 5C and 5D. The combined quota was increased to 1100 t in 1996. In 1997, the quota coverage was extended to include Area 5E. The total quota was 1000 t , of which 580 t and 420 t applied to the trawl and hook and line fisheries, respectively. The trawl fishery for lingcod in Areas 5C, 5D, and 5E was affected by the same management changes in 1996 as noted for Area 3 C , regarding quarterly trip limits, observers, and bycatch reduction measures.

For the 1999-2000 fishing year, a 65 cm (head-on) size limit was in place for all lingcod retained in the commercial fisheries. There was no size limit for lingcod retained in the recreational fishery. The quota allocations remained at 580 t for the trawl fishery, and 420 t for the hook and line fishery. A daily limit of 3 pieces applied to the recreational fishery.

### 5.4.2 Catch Statistics

Commercial catch statistics, including $25 \%$ Qualified catch, effort, and catch per unit effort (CPUE) for Areas 5C, 5D, and 5E were compiled in the same manner as for Area 3C (Table 9, Table 10, Table 11 and Table 12). Total catch in Areas 5C and 5D have ranged from less than 100 t prior to the 1940s to historic highs of around $750-850 \mathrm{t}$ in 1991 - 1995 (Table 9, Figure 3). Catches have historically been dominated by the trawl fishery, but line catches have exceeded trawl catches since 1998. Catches in Area 5E have ranged from less than 20 t / year prior to 1976, to a historic high of 216 t in 1999, and have been dominated by the hook and line fishery since the earliest recorded statistics in 5E in 1951 (Table 11, Figure 3).

American trawlers were active in Areas 5C and 5D until the declaration of the Canadian Fishing Zone in 1977. However, US trawl catch was not recorded until 1954. US trawl catch initially accounted for a high proportion of the total trawl catch ( $80 \%$ ), but the proportion fell steadily, and by 1963, US catch accounted for less than $20 \%$ of the total trawl catch (Table 9). From 1972 until 1982, US trawl catch averaged less than 1 t / year. No US catch has been recorded in Area 5E.

Total trawl catch and 25\% Qualified effort in Areas 5C and 5D began increasing in the early 1960s, and reached a high of 459 t and 531 h in 1971 (Table 10, Figure 3). Both catch and effort fell during the 1970s, but began to rise again in the early 1980s. Trawl catch reached historic highs of $750-850 \mathrm{t}$ in $1991-1995$, while effort peaked at 594 t and 679 t in 1991 and 1995, respectively. As in other areas of the coast, catch and effort dropped substantially after the introduction of new management measures in 1996. Trawl catch was only 67 t in both 1998 and 1999, while $25 \%$ Qualified effort was 117 and 76 h, respectively.

CPUE appears to have generally declined, with high peak values ( $800-900 \mathrm{~kg} / \mathrm{h}$ ) occurring in 1951-1965, a lower peak of $611 \mathrm{~kg} / \mathrm{h}$ in 1975, and peaks of 413 and $495 \mathrm{~kg} / \mathrm{h}$ in 1987 and 1994, respectively. CPUE in 1997-1998 was 176 and $113 \mathrm{~kg} / \mathrm{h}$, respectively, lower than the long term (1954-1999) median of $269 \mathrm{~kg} / \mathrm{h}$, while CPUE in 1999 was $260 \mathrm{~kg} / \mathrm{h}$, and quite similar to the long term median. In general, CPUE has been quite erratic over the time series, and Leaman and McFarlane (1997) suggest that the low level of the $25 \%$ Qualified effort renders the CPUE time series of questionable value.

Line catch in Areas 5C and 5D was small ( $<150 \mathrm{t}$ ) prior to the mid 1980s, but has accounted for an increasing proportion of the total catch in subsequent years and now represents
approximately half of the landings in the 1990s (Table 9, Figure 3). Lingcod has traditionally been incidental to the halibut and rockfish line fisheries, but in recent years, targeting on lingcod has increased (Leaman and McFarlane 1997).

Catches in Area 5E were exclusively from the hook and line fishery from 1951 1975, and totaled less than 20 t / year during this period (Table 11, Figure 3). Line catch has risen steadily since the mid 1980s, and has averaged about 120 t /year through the 1990s. In 1999, line catch reached a historic high of 216 t . As with Areas 5C and 5D, directed fishing for lingcod has increased in Area 5E, and may be responsible for the increase in 1999. Trawl catch from 1976-1999 was less than 30 t /year and accounted for about $16 \%$ of the total catch on average. Very few years had sufficient catch to meet $25 \%$ qualification levels (Table 12).

### 5.4.3 Size and age composition of commercial landings

There are a limited number of biological samples for Areas 5C/D and only 1 in $1997(\mathrm{n}=50)$ for Area 5E. Age samples for Areas 5C/D were available only for 1977, 1994, 1995 and 1997 (Figure 6). Only 1 or 2 samples were collected in each of these years. The average number of fish per sample was 93 , ranging from 53 to 121 . Length samples were available only for 1991, 1994-1996 and 1999-2000. The limited length information suggests that the mean size of males increased slightly after the size limit change in 1996, while the size of females did not change (Figure 7).

### 5.4.4 Climate-ocean regime considerations

At present, we do not have ecosystem information for Hecate Strait and west coast of the Queen Charlotte Islands. The regime shifts of 1977 and 1989 that produced abrupt changes in the Strait of Georgia and the west coast Vancouver Island ecosystems will have also had consequences for these areas, since those regime shifts were observed in basin-wide north Pacific climate-ocean systems. McFarlane et al. (2000) did note that several groundfish species in Hecate Strait exhibited above average year classes in the 1977 to 1988 regime, and below average year classes since 1989.

### 5.4.5 Condition of the stock

Based on the lack of a trend in the 5C/D CPUE index in recent years, there is no evidence that this stock is over exploited. However, caution is advised, as historic trawl effort levels in 5C/D may be too low to provide a reliable CPUE index. In addition, there is no CPUE index available in 5 E , and the rapidly expanding line fishery can provide little information about current stock status in this area. It is noted that several groundfish species in Hecate Strait have exhibited below average year classes since the 1989 regime shift.

### 5.4.6 Yield recommendations

A precautionary yield level of 1000 t was recommended for Areas 5C/D and 5E combined in 1997 (Appendix II Table A4; Leaman and McFarlane), and has remained at that level for subsequent years. We have no new information to revise the existing yield level, but recommend that managers adopt a conservative approach in consideration of the unreliable nature
of the CPUE index in 5C/D, and the rapidly expanding line fishery coupled with a lack of any relative abundance index in 5E. Given the ongoing expansion of the line effort in all areas, we recommend consideration of a winter closure similar to existing closures in other areas.

| 1999 | 249687 | 115473 | 493 | 234 | 38 | -- | 202 | 46.2 |

${ }^{1}$ Canadian trawl catch with associated effort data only: logbook data (source 1) from the GFCatch (1954-1995) and PacHarvest (1996-1999) databases (Fisheries and Oceans Canada, Pacific Region, Groundfish Data Unit).
${ }^{2}$ Qualified catch and effort is the lingcod catch and associated effort from landings occurring in May-September for those sets or events where the non-discarded lingcod catch is greater than $25 \%$ of the total catch.
${ }^{3}$ CPUE is based on tow-by-tow data after 1995; aggregated by tow within locality prior to 1995. Aggregation is simulated for 1991-1995, hence $\mathrm{N}_{\text {Events }}$ and $\mathrm{N}_{\text {Sets }}$ not available for these years. Each aggregate is considered one fishing "event."

Table 4. Lingcod recreational catch, effort, and CPUE for Barkley Sound, based on creel survey data during August and September, 1984-1992 (D. Lewis, pers. comm., Stock Assessment Division, Science Branch, Fisheries and Oceans Canada, 3225 Stephenson Point Road, Nanaimo, BC, V9T 1K3).

${ }^{1}$ Canadian trawl catch with associated effort data only: logbook data (source 1) from the GFCatch (1954-1995) and PacHarvest (1996-1999) databases (Fisheries and Oceans Canada, Pacific Region, Groundfish Data Unit).
${ }^{2}$ Qualified catch and effort is the lingcod catch and associated effort from landings occurring in May-September for those sets or events where the non-discarded lingcod catch is greater than $25 \%$ of the total catch.
${ }^{3}$ CPUE is based on tow-by-tow data after 1995; aggregated by tow within locality prior to 1995. Aggregation is simulated for 1991-1995, hence $\mathrm{N}_{\text {Events }}$ and $\mathrm{N}_{\text {Sets }}$ not available for these years. Each aggregate is considered one fishing "event."

Table 9. Lingcod commercial line, trawl, and total catches (tonnes) for Area 5C/D, 1927-1999. Superscripts correspond to sources of data and notes in Appendix I Table A1.

${ }^{1}$ Canadian trawl catch with associated effort data only: logbook data (source 1) from the GFCatch (1954-1995) and PacHarvest (1996-1999) databases (Fisheries and Oceans Canada, Pacific Region, Groundfish Data Unit).
${ }^{2}$ Qualified catch and effort is the lingcod catch and associated effort from landings occurring in May-September for those sets or events where the non-discarded lingcod catch is greater than $25 \%$ of the total catch.
${ }^{3}$ CPUE is based on tow-by-tow data after 1995; aggregated by tow within locality prior to 1995. Aggregation is simulated for 1991-1995, hence $\mathrm{N}_{\text {Events }}$ and $\mathrm{N}_{\text {Sets }}$ not available for these years. Each aggregate is considered one fishing "event."

Figure 1. Coast-wide lingcod commercial catch (Canadian Line, Canadian Trawl, U.S. Trawl) for British Columbia, 1927-1999.

Figure 2. Groundfish major statistical areas for the British Columbia Coast.

Figure 3. Total Canadian catch for the commercial lingcod hook and line fishery (1951-1998) and trawl fishery (1951-1999), and 25\% Qualified effort and CPUE for the lingcod trawl fishery (19541999), in the Strait of Georgia (Area 4B), off the west coast of Vancouver Island (Areas 3C and 3D), in Queen Charlotte Sound (Areas 5A and 5B), in Hecate Strait (Areas 5C and 5D) and off the west coast of the Queen Charlotte Islands (Area 5E). Note that for Area 5E, only five years had Qualified catch, and the $25 \%$ Qualified effort and CPUE plot is not shown.

Figure 3 (cont.).

Figure 4. Total trawl catch by month for lingcod caught off the west coast of Vancouver Island (Areas 3C and 3D) in 1990-1995, and 19961999.

Figure 5. Catch curves for lingcod caught in the trawl fishery off the west coast of Vancouver Island (Areas 3C and 3D), and in Queen Charlotte Sound (Area 5A/B), January to December, 1977-1999.

Figure 6. Proportion-at-age bubble plots for trawl-caught lingcod in Areas 3C, 3D, 5A/B and 5C/D, January-December, 1977-1999. Numbers along upper side of plots indicate number of specimens aged in each year.

Figure 7. Mean size of lingcod collected off the west coast of Vancouver Island (Areas 3C and 3D), in Queen Charlotte Sound (Areas 5A and 5B), and in Hecate Strait (Areas 5C and 5D), May-September, 1977-2000. Note that samples were not collected in all years.

## Appendix I: Lingcod commercial catch data for British Columbia

Table A1. Sources of lingcod commercial catch data (1927-1999).
No. ${ }^{\text {a }}$ Years and Data Type Sources and Notes

1. 1954-1974 Area 3C Trawl Catch
2. 1927-1946 Total Catch
3. 1945-1946 Line
4. 1945-1953 Canadian Trawl
5. 1945-1946 Area 3D Catch
6. 1947-1950 Line and Total Catch
7. 1951-1993 Line
8. 1954-1995 Canadian Trawl
9. 1954-1955 United States Trawl
10. 1956-1982 United States Trawl
11. 1994-1995 Line
12. 1996-1999 Line
13. 1996-1999 Trawl

Prior to 1975, no distinction was made between the Canadian and United States portions of Area 3C. Catch for these years therefore includes a small amount from U.S. waters.

Dominion Bureau of Statistics, Fisheries Division (in Waddell and Ware 1995). Catches were reported as dressed weight, DW (head and viscera removed; Wilby 1937), and converted to round weight, RW, using the formula RW $=1.39$ * DW (K. Rutherford, Pers. Comm.). Catch was not reported by gear type, but is known to be primarily from the line fishery, especially in nearshore waters (Forrester et al. 1978).
Calculated from the difference between (2) and (4)
Thomson and Yates (1960, 1961a, 1961b). Data obtained by Port Observers and supplemented with sales slip records.

Total catch (2) for these years in Area 3D was less than trawl catch (4) suggesting that an error may have occurred when the data was tabulated. Trawl catch is assumed to be correct, as it is based on two complementary DFO sources. Total catch and line catch are omitted.

No area totals available for line or total catch. Coastwide total catch reported in Dominion Bureau of Statistics, Fisheries Division (Appendix Table 2).

Obtained from Fisheries and Oceans Canada, British Columbia Catch Statistics Annual Reports which summarize catch from sales slip records. Catches were reported as dressed weight, DW (head and viscera removed; Wilby 1937), and converted to round weight, RW, using the formula RW = 1.39 * DW (K. Rutherford, Pers. Comm.). Catches for 1982-1993 were reported as round weight, but included the conversion factor for reference.

Obtained from the groundfish catch database, GFCatch (Fisheries and Oceans Canada, Pacific Region, Groundfish Data Unit). Catch data based on logbook records (source 1, catch and effort data) and/or sales slip records (source 2, no effort data).

Ketchen (1976).
Pacific States Marine Fisheries Commission, PSMFC (Will Daspit, Pers. Comm.). Prior to 1975 PSMFC reported Canadian and U.S. trawl data in combined format; therefore for 1954-1974, U.S. catch was determined by subtracting Canadian catch from the combined catch.

Obtained from the sales slip database, PacHarv3 (Fisheries and Oceans Canada, Pacific Region, Catch Statistics Unit).

Obtained from the sales slip database, PacHarv3 (Fisheries and Oceans Canada, Pacific Region, Catch Statistics Unit) and from the Dock-Side Monitored Hook and Line database, PacHarvHL (Fisheries and Oceans Canada, Pacific Region, Stock Assessment Division, Assessment Methods Section).

Obtained from the groundfish trawl observer database, PacHarvest (Fisheries and Oceans Canada, Pacific Region, Groundfish Data Unit).

## Appendix II: Management and quota history for British Columbia lingcod

Table A3. Management history for British Columbia lingcod
a) Commercial Fishery

| Year | Event |
| :--- | :--- |
| 1920 s | Start of 4B winter closure in the Gulf Island region (Dec. to Feb.). |
| 1942 | Start of coastwide size limit of 58 cm. |
| 1979 | Extension of 4B winter closure (Nov. 15 to Apr. 15). |
| 1987 | Start of mandatory logbooks; <br> start of winter closures in 3C/3D/5A offshore (Jan. 1 to Apr. 15) and 3C/3D inshore (Nov. <br> 15 to Apr 15). |
| 1988 | Extension of 3C/3D/5A offshore and inshore winter closures (Nov. 15 to Apr. 30). |
| 1989 | Extension of 4B size limit to 65 cm. |
| 1991 | First year-round closure in Strait of Georgia. |
| 1993 | Start of Dockside Monitoring Program. |
| 1996 | Extension of coastwide size limit to 65 cm; <br> suspension of trawl winter closure; <br> start of trawl observer program, bycatch limits for halibut, and counting of all quota species <br> including discards against vessel period limits. |
| 1997 | Switch to April 1 - March 31 fishing year; <br> 1 st individual vessel quota (IVQ) year; <br> expansion of dockside monitoring program and hail out requirements to include all <br> Schedule II trawl licenses except when landed with salmon. |

b) Recreational Fishery

| Year | Event |
| :--- | :--- |
| 1979 | Start of 4B winter closure (Nov. 15 to Apr. 15). |
| 1991 | Extension of 4B winter closure (Oct. 1 to May 31); <br> start of 4B size limit of 65 cm. |
| 1992 | Start of 3C/3D winter closure (Oct. 1 to May 31). |
| 1999 | Start of 3C/3D size limit of 65 cm. |

Table A4. Yield options and recent commercial TACs and catches for lingcod in British Columbia.

| Area | Data Available | 2001/02 <br> Recommended Yield | $\begin{array}{\|c} 2000 / 01 \\ \text { Commercial } \\ \text { TAC } \\ \hline \end{array}$ | 1999/2000 |  | Previous Yield Options |
