${ }^{1}$ This series documents the scientific basis for the evaluation of fisheries resources in Canada. As such, it addresses the issues of the day in the time frames required and the documents it contains are not intended as definitive statements on the subjects addressed but rather as progress reports on ongoing investigations.
${ }^{1}$ La présente série documente les bases scientifiques des évaluations des ressources halieutiques du Canada. Elle traite des problèmes courants selon les échéanciers dictés. Les documents qu'elle contient ne doivent pas être considérés comme des énoncés définitifs sur les sujets traités, mais plutôt comme des rapports d'étape sur les études en cours.

Les documents de recherche sont publiés dans la langue officielle utilisée dans le manuscrit envoyé au Secrétariat.

Ce document est disponible sur l'Internet à: Ce documes.g.ca/csas/

#### Abstract

An age disaggregate index of abundance was derived from both the gillnet and linetrawl sectors of the sentinel survey in NAFO Divisions 2J3KL. A generalized linear model was applied to the catch and effort data at age for each gear and survey method with an assumed Poisson distribution for catches. Through the use of different gears which have very specific selectivities, it is possible to track year-classess through the five years the sentinel program has been operational..

## Résumé

Un indice de l'abondance par classe d'âge a été tiré des secteurs de la pêche à la senne et de la pêche à la palangre du relevé sentinelle effectué dans les divisions 2 J 3 KL de l'OPANO. À l'aide d'une hypothèse de distribution de Poisson pour les captures, on a appliqué un modèle linéaire généralisé aux données sur les prises et l'effort selon l'âge pour chaque engin et méthode de relevé. L'utilisation de différents engins comportant des sélectivités très particulières permet de suivre les classes d'âge au cours des cinq années d'application du programme des pêches sentinelles.

## Introduction

The sentinel program has been running in NAFO Division 2J, 3K and 3L since 1995 giving five complete years of catch and effort data from 60 sites. Lengths and weights have been sampled by quarter in all sites over the portion of the year the program is in operation. . A detail description of the sentinel program is given in Maddock Parsons et al. (2000).

In the last assessment (March 1999) an age-aggregated standardised catch rate series was derived for both the gillnet and line trawl portions of the sentinel program. In this assessment an attempt is made to produce an age-disaggregated index of abundance for the five years of gillnet and linetrawl data.

## Methods

Catch-at-age
The catch from the sentinel program in 2 J 3 KL are divided into cells defined by Gear type (gillnet $51 / 2$ inch, gillnet $31 / 4$ inch and line trawl), NAFO Division (2J, 3K, 3L), and Divisions broken down into Statistical unit area (i.e. 3Ki 3Lh etc.), Year (1995-99) and Quarter. Age-length keys are generated for each cell using fish sampled from both fixed and experimental sentinel survey sites. Experimental sites are fished at the discretion of the fishermen in various locations in the general vicinity of the fixed site. There were no fixed sites using $31 / 4$ gillnets. Length frequencies and age-length keys were combined by cells. Numbers of fish at length were assigned an age using the age-length key for the cell. When there was a lack of sampling cells were collapsed into larger ones until all fish are assigned an age. For example, if there were non-matches by quarter then quarters were combined to the half-year; and if necessary half-years were combined to the year. If necessary unit areas were combined within division for the year. The last level of collapse is to adjacent 3 cm length grouping within gear, division and year survey. Because there are little to no discards in the sentinel program and the fishermen sample all of the fish for line trawl and gillnet sets, catch numbers-at-age can be reliably produced for these two gears.

## Standardization

The catch-at-age and catch per unit effort (CPUE) were standardised to remove seasonal and spatial effects. Results from an informal working group at the 1999 Rimouski Zonal Assessment meeting suggested that for gillnet, only sets fished during July to November with a soak time between 18 and 24 hours should be included in the analysis. For line trawl, sets fished during August to November with a soak time less than or equal to 12 hours are selected. Zero catches were generated for ages not observed in a set. Sets with
effort but no catch are valid entries in the model. Ages in the model ranged from 3 to 10 for $5 \frac{1}{2}$ inch gillnet, 2 to 10 for $31 / 4$ inch gillnet and 3 to 9 for linetrawl. A generalized linear model (McCullagh and Nelder 1989) was applied to the catch and effort data for each gear and survey method. The response distribution was specified as Poisson and the link function was chosen to be log. That is, the Poisson mean parameter $\mu_{i}$ is related to the linear predictor by

$$
\log \left(\mu_{i}\right)=X_{i}^{\prime} \beta
$$

where $X_{i}$ is a vector of explanatory factors for catch observation $i$ (i.e. month, site, age and year) and $\beta$ is a vector of coefficients to be estimated from the data.

Thus catch is assumed to have a Poisson probability distribution with the mean $\mu_{i}$ related to the factors month nested within site and age nested within year by

$$
\log \left(\mu_{i}\right)=\log \left(E_{i}\right)+\text { month }_{i}(j) \beta_{j}\left(\text { site }_{i}(k) \beta_{k}\right)+\text { age }_{i}(l) \beta_{l}\left(\text { year }_{i}(m) \beta_{m}\right),
$$

where $E_{i}$ is and offset parameter for fishing effort and $j, k, l, m$ indicate the level for each of the four factors, for example June for the factor month, and where

$$
\text { month }_{i}(j)=\left\{\begin{array}{l}
1 \text { if month }=j \\
0 \text { if month } \neq j
\end{array} .\right.
$$

Fishing effort was measured in terms of number of nets for gillnets and number of hooks for line trawls. Expected catch per unit of effort for each age in each year were computed for the two gear types from the estimated parameters to obtain relative indices of population numbers at age that could be used in further analyses of the status of the stock.

## Results

## Gillnet 3-1/4 inch Experimental Survey

The number of sets and summary statistics for soaktime for $3-1 / 4$ inch gillnets are given in Table 1.1. Table 1.2 gives the number of hauls entering the model after applying soak time and season selection limits described under methods. Forty four percent of the set were excluded from the analysis, mainly due to failure to meet soak time criteria. All but one haul used only a single net for sampling out of 486 sets (Table 1.3). Catch at age data for $3-1 / 4$ inch gillnets are given by division in Table 1.4 for the period 1996 to 1999. Catch was low in 1995 in all divisions and increased up to 1998 and declined in 1999. The dominate age taken with this gear is age 4 for all years in 2 J 3 K except 1999 in 3 K where the modal age was 3. In Division 3L however, the modal age varied from age 6 in 1996 to age 3 in 1997, back to age 6 in 1998 and back to age 3 in 1999. Month and site
combinations that had zero catches for all years in the sentinel survey are listed in Tables 1.5. These cells were removed from the analysis.

In the model output (Table 1.6) SEQCODE is a sequential community (site) code starting with 1 in Black Tickle in Labrador and ending with 60 at Point Lance on the southern Avalon Peninsula. Parameter estimates and standard errors are given in Tables 1.6. The parameters of interest are labelled Age (Year). The values with the high STD. ERR are associated with very low catch numbers at age in that year. The type 3 likelihood ratio statistics show all effects are significant (Table 1.6 page 14). The lsmeans for the Age (Year) parameter estimate are transformed to arithmetic scale in Table 1.7 to give the standardized relative mean numbers per net at age. The scale parameter is estimated to be 3.44 indicating that the data may be over-dispersed as a consequence of outliers. This is of interest and needs to be investigated in further studies. Person residuals, the square root of the $i$ th contribution to the Pearson's chi-square, are plotted against predicted values (Fig. 1). The observed pattern is due to a high frequency of zero and ones in the data.

The procedure described above is adopted for the four other gear/survey type combinations. Major differences for each gear/survey type are highlighted below.

## Linetrawl Fixed Survey

Forty percent of the sets were excluded from the analysis for failure to meet soak time criteria leaving 628 sets to be used in the analysis (Table 2.2). The overall mean soak time dropped from 15 hours to 3 hours after selection Gear amount ranged from 150 1000 hooks per set (Table 2.3). Catch at age data for the Sentinel line trawl by division are given in Tables 2.4. Catch was higher in 1995 and 1997 and lowest in 1999 in Divisions 3KL. Linetrawl was not used to any great extent in the sentinel program in 2 J . The dominant age taken with this gear is age 5 except for Division 3K in 1995 for which the modal age was 4 . Site locations for this run ranged from Coachman's Cove in White Bay to River Head, St. Mary's Bay. There were only 21 sites using linetrawl in 3KL.

## Linetrawl Experimental Survey

Thirty four percent of the set were excluded from the analysis, mainly for failure to meet soak time criteria, leaving 796 sets to be used in the analysis (Table 3.3). The overall mean soak time dropped from 14 hours to 3 hours after selection. Gear amount ranged from $50-1000$ hooks per set, $($ mode $=350)($ Table 3.3). Catch at age are given by division in Table 3.4. Catch was similar to that taken with linetrawl in the fixed survey. For this analysis the most northern site was St. Charles in southern Labrador and ending at River Head St. Mary's Bay. There were 23 sites using linetrawl in 3KL.

## Gillnet $51 / 2$ in. Fixed survey

Forty three percent of the set were excluded from the analysis for failure to meet soak time criteria leaving 2463 sets to be used in the analysis (Table 4.3). Gear amount ranged from 1- 4 nets per set with most using 2 nets (Table 4.3). Catch at age are given by division in Table 4.4. Catch was higher in 1996 and 1998 and lowest in 1995 in all divisions. Division 3L had the highest catch and there was very little catch in 2J. The dominant ages taken with this gear were age 6 and 7 . This survey covers the full range of the sentinel survey from southern Labrador to Point Lance on the southern Avalon Peninsula.

## Gillnet 5 ½ in. Experimental Survey

Forty three percent of the sets were excluded from the analysis, mainly for failure to meet soak time criteria leaving 3786 sets to be used in the analysis (Table5.2). This survey method had 1323 sets more than the fixed gillnet survey. Gear amount ranged from 1-5 nets per set with most using 2 (Table 5.3). Catch at age are given by division in Table 5.4. Catch was similar to that taken with the $5 \frac{1}{2}$ in. gillnet in the fixed survey.

## Age disaggregated indices by Gear and survey method

Age disaggragated indices by Gear and survey type are given in Figure 2. Year-classes can be followed sequentially from $3 \frac{1}{4}$ inch gillnets through the linetrawl fishery to $5 \frac{1}{2}$ inch gillnet. This is illustrated for the 1990 and 1992 year-classes for experimental survey sites (Figure 3). The 3-1/4 inch gillnet catches predominately age $4 \operatorname{cod}$ while the linetrawl catches age 5 and $5 \frac{1}{2}$ inch gillnet catches age 6 and 7 .

## Discussion

It is the intent to use the gillnet and linetrawl standardized catch rate at age as indices of abundance, at least, for the inshore range of the northern cod stock. For3Ps cod stock on the south coast of Newfoundland an age dissagregate index from the gillnet fishery in the sentinel program was used in the calibration of the SPA (Brattey et al. 1999).

The sentinel survey is the only sampling program that covers a large geographical range for the inshore portion of the stock. The model removes seasonal and spatial effects from the raw data to give a standarized index of cod abundance for the five years the program has been running.

The strength of any index is its ability to track year-classes. The catch rate series derived from the sentinel program using three different fishing gears that have different size selectivity characteristics appears to show year classes that track through the gears. It is important therefore that the Sentinel Program continue using all three gears in order to
track relative weak year classes. There appears to be little difference in the age structure sampled within gear for the different survey methods (Fixed vs. Experimental) although this was not formally tested in the present analyses. The apparent lack of difference is not surprising given the close proximity of the experimental sites to the fixed sites.

Large numbers of fish were sampled for age and length frequencies. However, $42 \%$ of the catch/effort data did not enter the model due to failure to meet the selection criteria established by the ad hoc working group at the Zonal cod stock Assessment Meeting in Rimouski in 1999. Most of these data were rejected due to long soak times. No methods have been developed to date to model the sentinel catch/effort data with soak time as a covariate. It was felt at the Rimouski Zonal Assessment that investigations into the functional forms might not be productive but the meeting conceded that the relationship between soak time and abundance remains an unsolved issue.

The five model runs were all over dispersed as indicated by the scale parameter greater than 1 . This is a phenomenon that sometimes occurs in models with a Poisson distribution; however all statistics are adjusted appropriately using the deviance divided by degrees of freedom as an estimate of the multiplicative overdispersion factor. (SAS Institute Inc). Nevertheless, alternative models, such as the negative binomial, should be explored and the sensitivity of the estimates to the assumed model examined.

Given that the different kinds of sentinel data are different but not completely independent, and given the ability to track year-classes through survey types, there may be some advantages in putting all the data into a single analysis which includes survey type as a factor. This will be explored in future analyses.
