#### Abstract

A large-scale mark-recapture study of adult ( $>45 \mathrm{~cm}$ ) Atlantic cod (Gadus morhua), initiated in spring 1997, was continued. During 1997-2002 a total of 26,401 live cod were tagged with single, double, or high-reward t-bar anchor tags and released at various inshore locations off the east coast of Newfoundland. Approximately 3,870 tagged cod have been reported as recaptured up to 8 February 2003. Tag returns were adjusted to account for region-specific reporting rates, and the number of tagged cod available for capture was adjusted to account for tagging mortality, tag loss and assumed natural mortality. These data were used to estimate annual exploitation rates for each batch of tagged cod. To indicate where exploitation was taking place, the spatial distribution of recaptures from tagging in each area was summarized annually, with numbers recaptured adjusted to account for annual region-specific reporting rates. Estimates of exploitation for cod tagged in 3K in 1999 were high (29-63\%) for 1999, but dropped dramatically (3.9-8.8\%) during 2000 and 2001. Landings in 3 K dropped from about $3,500 \mathrm{t}$ in 1999 to only 600 t in 2002. Among cod tagged in Bonavista Bay (3La), estimates of exploitation were also highest for 1999 , ranging from 6.0 to $18.4 \%$ with most estimates around $15 \%$. Estimates for subsequent years were lower, except among more recently tagged cod released in 3La during 2001 and 2002 ( $4.5-24.5 \%$ ). Estimates of exploitation for cod tagged in Trinity Bay (3Lb) during 1999 tended to be lower (3.5-13.2\%) than those for Bonavista Bay. For 2000 and 2001 most estimates for cod tagged in 3Lb were between 5 and $15 \%$. There was a marked increase in the estimates for 3 Lb during 2002, particularly among cod tagged in Smith Sound where 5 of 12 estimates exceeded $20 \%$ giving cause for concern; most of the exploitation of these cod occurs outside Smith Sound as these fish disperse northward during summer. The exploitation estimates for Conception Bay (3Lf) and the eastern Avalon (3Lj) tended to be low $(<10 \%)$ and annual reported landings in these regions were low (300-600 t) throughout 19982002. In contrast, cod tagged in St. Mary's Bay (3Lq) were more heavily exploited throughout 1998-2002 with 19 of 25 annual estimates exceeding $15 \%$. Most of the exploitation of cod tagged in southern 3L occurs in Placentia Bay (3Psc), suggesting that many of the fish in this area are migrants from the neighbouring stock area. Cod in the inshore of northern 3 L and 3 K appear to comprise a separate stock component and do not appear to mix to any great extent with cod from southern 3L or 3Ps.

## Résumé

Une étude de marquage-recapture à grande échelle de la morue de l'Atlantique (Gadus morhua) adulte ( $>45 \mathrm{~cm}$ ) lancée au printemps de 1997 s'est poursuivie. De 1997 à 2002, un total de 26401 morues vivantes ont été marquées au moyen d'étiquettes à ancrage en T à récompenses simples, doubles ou élevées avant d'être remises à l'eau à divers endroits dans les eaux côtières de l'est de Terre-Neuve. Le 8 février 2003, on avait signalé la recapture d'environ 3870 morues marquées. Nous avons corrigé les nombres de recaptures en fonction du taux de déclaration propre à la région et nous avons corrigé le nombre de morues marquées disponibles à la pêche pour tenir compte de la mortalité due au marquage, des étiquettes perdues et de la mortalité naturelle présumée. Ces données ont ensuite servi à estimer les taux d'exploitation annuels de chaque lot de morues marquées. Pour indiquer où l'exploitation avait eu lieu, nous avons résumé les répartitions spatiales annuelles des recaptures dans chaque région en corrigeant les nombres de recaptures selon le taux de déclaration annuel propre à chaque région. Les taux d'exploitation estimés pour les morues marquées en 1999 dans 3 K étaient élevés (29-63 \%) en 1999, mais ils ont baissé énormément ( $3,9-8,8 \%$ ) en 2000 et en 2001. Les débarquements dans 3 K ont chuté d'environ 3500 t en 1999 à seulement 600 t en 2002. Quant aux morues marquées dans la baie Bonavista (3La), les taux d'exploitation estimés étaient les plus élevés en 1999 : ils variaient entre 6 et $18,4 \%$, la plupart s'approchant de $15 \%$. Ces estimations étaient plus basses les années suivantes, à l'exception des morues marquées plus récemment et remises à l'eau dans 3 La en 2001 et en 2002 (4,5-24,5 \%). Les morues marquées dans la baie de la Trinité (3Lb) en 1999 donnaient généralement des taux d'exploitation (3,5-13,2 \%) inférieurs à ceux calculés pour les morues de la baie Bonavista. En 2000 et en 2001, la plupart des taux d'exploitation estimés pour les morues marquées dans 3 Lb variaient entre 5 et $15 \%$. En 2002, les estimations ont considérablement augmenté pour 3 Lb , particulièrement pour les morues marquées dans le bras de mer Smith, où cinq des douze estimations dépassaient $20 \%$, ce qui est inquiétant ; ces morues sont surtout exploitées à l'extérieur du bras Smith, car elles se dispersent vers le nord, le long de la côte, durant l'été. Les taux d'exploitation estimés dans la baie Conception (3Lf) et à l'est de la presqu'île Avalon ( 3 Lj ) étaient généralement faibles ( $<10 \%$ ) et les débarquements annuels déclarés étaient peu élevés (de 300 à 600 t ) dans ces régions de 1998 à 2002. Par contre, la morue était exploitée plus intensément dans la baie St. Mary's (3Lq) de 1998 à 2002:19 des 25 estimations annuelles ont dépassé $15 \%$. L'exploitation des morues marquées dans le sud de 3L se fait surtout dans la baie Placentia (3Psc), ce qui porte à croire que bon nombre de morues dans cette région proviennent de l'aire de stock voisine. Les morues peuplant les secteurs côtiers de 3 K et du nord de 3 L semblent former une composante de stock distincte qui se mélange peu avec les morues de 3Ps ou du secteur sud.

## Introduction

A mark-recapture study of Atlantic cod (Gadus morhua) in NAFO Divs. 3KL, initiated during 1997, was continued in 2002. The purpose of the study was to provide information on movement patterns and stock structure of inshore cod as well as obtain estimates of exploitation rates on cod tagged in different inshore regions. Annual estimates of exploitation are given for each tagging experiment conducted in 3KL during 1997-2002. The method for estimating exploitation is similar to that described in Brattey et al. (2001a, 2002) except that a new method of accounting for tag loss is incorporated (Cadigan and Brattey 2003). This document also gives a synopsis of the spatial and temporal distribution of recaptures of tagged cod released in various regions of Divs. 3KL during 1997-2002 and reported as recaptured up to the end of December 2002. Information on stock structure and seasonal movement patterns from other postmoratorium cod tagging studies is reported in previous documents (Lawson et al. 1998; Brattey 1999, 2000; Brattey et al. 1999). Historical cod tagging studies (prior to 1994) in the Newfoundland Region are summarized in Taggart et al. (1995), Myers et al. (1996, 1997). Further analyses of the data from the current experiments are presented elsewhere (Cadigan and Brattey 1999a, b; 2000a, b; 2002; Lilly et al. 2001; Pope and Brattey 2001).

## Materials and Methods

Cod for tagging were captured with various gears (mostly hand-line), measured (nearest cm ) and tagged with one or two t-bar anchor tags inserted at the base of the first dorsal fin, and released. Experienced technicians conducted the tagging. Only cod $\geq 45 \mathrm{~cm}$ (fork length) that appeared healthy were tagged and each batch of cod typically consisted of individuals tagged with either single, double, or high-reward tags. The tags were uniquely numbered and bore a return address as well as the value of the reward ( $\$ 10$ for one single, $\$ 20$ for two singles, or $\$ 100$ for high-reward). The tagging program was advertised extensively among those participating in the fishery. Details of the tagging experiments are summarized in Table 1. The number of cod tagged was only 118 in 1998 but ranged from 3414 to 8,268 in 1999-2002. The sizes of tagged cod ranged from 45 to about 115 cm with mean lengths mostly in the $55-65 \mathrm{~cm}$ range. Approximately 100 tagging experiments have been conducted at various sites from Notre Dame Bay ( $3 \mathrm{Kh} / \mathrm{i}$ ) in the north to St. Mary's Bay (3Lq) in the south (Fig. 1).

Reported landings of cod from 3KL during the period 1998-2002 were extracted from the Statistics Branch catch database and are summarized to aid in the interpretation of tag returns.
Corresponding landings for the adjacent management unit (3Ps) are also given for the period 19972001 (complete landings for 2002 were not available).

## Estimation of exploitation rates

The methods used to estimate exploitation rates are similar to those described in Brattey et al. (2001a, 2002). The number of reported recaptures from individual cod tagging experiments gives minimum estimates of the exploitation rates on the aggregations of cod that were tagged. However, in practice, not all fish survive tagging, some tags fall off the fish particularly in the first year, and not all recaptures of tagged fish are reported. Tagged (and untagged) cod also suffer natural mortality due to factors such as predation and disease. Accounting for these losses leads to a reduction in the number of tagged (and untagged) animals available to the fishery. We used information from companion studies to estimate these losses. In this analysis we estimated exploitation rates for cod tagged in a specific area at a specific time (i.e. individual tagging experiments), irrespective of where recaptures came from. In many mark-recapture applications, the tagged animals are assumed to mix throughout the population; we do not make this assumption in the current analyses, but do assume that the tagged animals were not selectively exploited within the component of the stock that was tagged. Our results typically show that even within a few months after release, tagged cod undergo considerable movements away from the tagging sites. Only releases in 3KL in 1997-2002 were used in this analysis. We did not attempt to estimate population sizes using tag returns and commercial catches in this analysis, because typically some harvesting occurs in an area different from where fish were tagged; this makes it difficult to convert local catches to local population biomass. Analyses of the tagging data that include methods to estimate cod biomass are presented elsewhere (Lilly et al. 2001; Pope and Brattey 2001; Cadigan and Brattey 2001, 2002).

Tag-induced mortality ( $\tau$ ) was estimated by retaining tagged cod in submersible cages for periods of 5-10 days and monitoring their survival (Brattey and Cadigan 2001). An estimate of 0.13 was obtained from these studies indicating $13 \%$ of tagged cod succumb "immediately" after tagging. This value was used for all experiments (i.e. $1-\tau=0.87$ survived tagging).

Our method of estimating reporting rate $(\lambda)$ is based on a high-reward tagging study, described in detail in Cadigan and Brattey (1999a, 2000a, 2003) and updated with recent recaptures. We used annual, region-specific estimates of reporting rate calculated from the high-reward tagging study; high-reward tags were assumed to have a reporting rate of 1.0.

Tag loss rates ( $\phi$ ) were estimated from a double-tagging study (see Cadigan and Brattey 2003), which showed that tag loss mostly occurred in the first 3-4 months after release with only minimal losses thereafter. We used a model that was proposed by Kirkwood (1981) to estimate tag loss rates

$$
\phi_{t}=\left(\left(\beta_{0} /\left(\beta_{0}+\beta_{I} t\right)\right)^{\beta 0} ; \beta_{0,} \beta_{1} \geq 0\right.
$$

where $t$ is the time at liberty. For each recapture year, we computed a time at liberty, which in the first year corresponds to the number of weeks between the median date of release of tagged fish and the median recapture date of tagged individuals in the year of release. For subsequent years, time at liberty is calculated by incrementing the number of weeks between the annual median dates of recapture.

New analyses (Cadigan and Brattey 2003) has shown that the rate of loss of tags depends on position and that the front tag of a double tagged fish is lost at a faster rate than the back tag; thus there are three types of recapture from a double tagged fish: (the front tag only, the back tag only, or both tags). The tag loss model was used to compute the proportion of initial number of tags applied that were retained at the median date of recapture for each recapture year. This was done separately for each type of tag return. The instantaneous rate of natural mortality $(m)$ assumed to be 0.2 per yr. To estimate exploitation annually, we tracked the numbers of fish available for capture in each year, accounting for tag loss and assumed natural mortality. The recaptures from each region $(R)$ were adjusted by the reporting rate $\left(R^{*}\right)$. In the initial year, we immediately removed those cod that die "instantly" due to tagging mortality. The estimates of "loss" are actually retention rates ( $\phi$ ) using Kirkwood's model and apportioned by the time at liberty. Natural mortality $(m)$ was also apportioned by the time-at-liberty, i.e. $e^{-m(t / 52)}$

Let $M(t)_{\text {eff }}$ denote the "effective" number of tagged fish available in year $t$ prior to the fishery. After the fishery in year $t$, let next $_{t}$ denote the number of tagged fish remaining. For fish having a single tag, in the year of release, if $T_{0}$ is the number of fish tagged and released,

$$
M(0)_{e f f}=T_{0}(1-0.13) \phi_{0} m_{0}
$$

and

$$
\text { next }_{0}=M(0)_{e f f}-R_{0}^{*} .
$$

In subsequent years,

$$
M(t)_{e f f}=\operatorname{eext}_{t-1} \delta_{L_{t}} \delta_{m_{t}}
$$

where

$$
\delta_{L_{t}}=\phi_{t} / \phi_{t-1} \text { and } \delta_{m_{t}}=m_{t} / m_{t-1},
$$

and

$$
\text { next }_{t}=M(t)_{e f f}-R_{t}^{*}
$$

Note that $\delta_{L t}$ and $\delta_{m t}$ are the proportion of additional tag loss and natural mortality to be removed from the available population. We use such ratios because the values of $N$ and $m$ are relative to the initial numbers of tagged cod.

For fish that are double-tagged and released, additional attention is required when adjusting the annual loss rates and computing the effective number of tagged fish remaining. For example, in any given year, a double-tagged fish may lose neither or both tags, or, could lose only the anterior or posterior tag. First, consider those fish that have retained both of the tags:

$$
M(0)_{e f f}=T_{D 0}(1-0.13) \phi_{A_{-} 0} \phi_{B_{-} 0} m_{0}
$$

where $\phi_{A_{-} 0}$ and $\phi_{B_{-} 0}$ represent the tag retention of the anterior and posterior tags, and $T_{D 0}$ is the number of double-tagged fish released. After the fishery in the initial year,

$$
\operatorname{next}_{0}=M(0)_{e f f}-R_{0}^{*}
$$

In subsequent years,

$$
M(t)_{e f f}=\operatorname{next}_{t-1} \delta_{L_{t}} \delta_{m_{t}}
$$

where

$$
\delta_{L_{t}}=\phi_{A_{-} t} \phi_{B_{-} t} / \phi_{A_{-}(t-1)} \phi_{B_{-}(t-1)} \text { and } \delta_{m_{t}}=m_{t} / m_{t-1}
$$

so the loss adjustment is made for both tags. After the fishery, we again have

$$
\text { next }_{t}=M(t)_{\text {eff }}-R_{t}^{*}
$$

Double-tagged fish that lose one of their tags create two additional types of return to track: those that have the anterior tag only, and those that have the posterior tag only. In the first year, such individuals can only come from the double-tagged fish. However, in subsequent years, individuals with only the anterior tag come from two sources: those that had both tags in the previous year, or those with only the anterior tag (which was retained) in the previous year. Thus, the number of individuals available to the fishery with the anterior tag only can increase over time. The identical situation exists for the individuals retaining the posterior tag. The expressions below indicate how we track fish that have the anterior tag (only) in place. In the year of release,

$$
\begin{gathered}
M(0)_{e f f}=T_{D 0}(1-0.13) \phi_{A_{-} 0}\left(1-\phi_{B_{-} 0}\right) m_{0}, \text { and } \\
\text { next }_{0}=M(0)_{e f f}-R_{0}^{*}
\end{gathered}
$$

In subsequent years, (keeping in mind that individuals with the anterior tag come from two sources as described above),

$$
M(t)_{e f f}=\operatorname{next}_{t-1} \delta_{L_{A_{-}}} \delta_{m_{t}}+\operatorname{next}_{D(t-1)} \delta_{L_{-} D_{t}} \delta_{m_{t}}
$$

where

$$
\delta_{L_{A_{-} t}}=\phi_{A_{-} t} / \phi_{A_{-}(t-1)}, \delta_{L_{-} D_{t}}=\phi_{A_{-} t} / \phi_{A_{-}(t-1)}\left(1-\frac{\phi_{B_{-} t}}{\phi_{B_{-}(t-1)}}\right) \text { and } \delta_{m_{t}}=m_{t} / m_{t-1}
$$

Here, ext $_{D_{D(t-1)}}$ refers to the numbers of fish with both tags remaining available, $\delta_{A_{-} t}$ is the tagloss adjustment for individuals having the anterior tag only in the previous year, and $\delta_{L_{-} D_{t}}$ is the tag-loss adjustment for double tagged fish in the previous year which have lost the posterior tag since the previous years fishery. Again we have

$$
\text { next }_{t}=M(t)_{e f f}-R_{t}^{*} .
$$

Similar expressions are used to account for the numbers of fish available having the posterior tag only.

The exploitation rate $\mu(t)$ in year $t$ for each experiment is estimated by summing the adjusted number of recaptures across tag types and dividing by the summed numbers of each tag type available to the fishery, i.e.:

$$
\mu(t)=\frac{\sum_{k} R_{t(k)}^{*}}{\sum_{k} M(t)_{e f f(k)}} .
$$

The subscript $k$ represents available tag types at time $t . M_{\text {eff }(k)}$ is the number of type $k$ tags available at the time of the fishery in each year. Note that the annual median time at liberty is common across tag types within an experiment. Tagging experiments were conducted in consecutive years in some locations; thus multiple annual estimates of exploitation are given for some locations. Note that in some years tagged fish were released during the fishery and the first estimate of exploitation for these releases accounts for only a portion of the total exploitation in that year.

## Results

## Spatial and temporal distribution of cod landings

Reported monthly landings of cod are summarized by unit area for the period 1998-2002 (Table 2A). The total allowable catches (TAC's) in these years were $5,000 \mathrm{t}, 9,000 \mathrm{t}, 7,000 \mathrm{t}, 5,600 \mathrm{t}$, and $5,600 \mathrm{t}$, respectively. Reported landings from the commercial fishery have been substantially less than the TAC for the past three years; however, total landings exceeded the TAC in 2001 because of the large recreational fishery catch. The spatial patterns in landings show a distinct pattern; initially highest landings come from adjacent areas in southern 3 K and northern 3 L , particularly Fogo-Twillingate (3Ki) Bonavista Bay (3La) and Trinity Bay (3Lb). Landings decline rapidly further northward towards Notre Dame Bay (3Kh) and the White Bay-Northern Peninsula area ( $3 \mathrm{Kd}, 3 \mathrm{Ka}$ ). Landings from southern 3L (i.e. Conception Bay southward, areas $3 \mathrm{Lf}, 3 \mathrm{Lj}$, and 3 Lq ) tend to be much lower. Reported offshore landings from $2 \mathrm{~J}+3 \mathrm{KL}$ (not shown) have been extremely small ( $<50 \mathrm{t}$ ) throughout 1998-2002.

The distribution of total landings across unit areas is shown in Fig. 2. The most notable change in landings over the past five years is the dramatic decline in the proportion of landings in all unit areas in 3 K and corresponding increase in 3Lb (Trinity Bay).

The total allowable catches (TAC's) in NAFO Subdiv. 3Ps in the post-moratorium period were substantially higher than those in 3 KL , ranging from $10,000 \mathrm{t}$ in 1997 to $25,000 \mathrm{t}$ in 1999. The
spatial patterns in landings were broadly similar each year with highest landings ( $30-50 \%$ of the entire TAC) coming from Placentia Bay (3Psc), followed by the offshore region 3Psh.

## Numbers of recaptures

For each experiment, details of the numbers of tagged cod reported as recaptured annually up to the end of 2002 are summarized in Table 1. These recaptures are for all tag types combined and are not adjusted by reporting rates. These data show that tagged cod from many experiments are still being recaptured $4-5 \mathrm{yr}$ after release.

## Reporting rates

Annual and region specific estimates of reporting rate obtained using the methods described in Cadigan and Brattey (2003) are shown in Table 2. The reporting rates were generally high ( $>66 \%$ ) for most regions; the only exception was for single tag returns from 3Pn-4R where the estimates were generally lower (38.0-70\%). Reporting rates for double tagged cod tended to be higher than those for single tagged cod, particularly during 1997-2000. There is also some indication of a temporal trend in reporting rates for both tag types with an increase trend during 1997-2001 and a marked drop in 2002 in all regions.

## Tag loss and natural mortality

The results from the double tagging study indicate that cod lose about $24 \%$ of the tags in the anterior position during the first year. (Fig. 3). Thereafter the loss rate diminishes and further losses amount to about $1-2 \%$ per year for up to almost 6 years at liberty. The loss rate for tags in the posterior position is somewhat lower in the first year at about $12 \%$, but similar to that of anterior tags in subsequent years. Assumed natural mortality at a rate of 0.2 per year would result in loss of an additional $18 \%$ of tagged cod per year irrespective of tag type. These findings indicate that due to a combination of initial tagging mortality, tag loss, and natural mortality a considerable fraction of the tags on single and high-reward tagged cod disappear in the first year, irrespective of those removed from the population by the fishery.

## Exploitation rates

Annual estimates of exploitation rate for each tagging experiment (only for experiments where $>$ 100 cod were tagged) are summarized and grouped by area of release in Table 4. Since tagging has been conducted in some locations for several years, there is a sequence of annual estimates of exploitation for many areas. Note that growth and length selectivity are not formally taken into account in this analyses; thus, the estimates for recently tagged fish pertain to cod $>45 \mathrm{~cm}$ (approximately aged $4+$ ), whereas estimates for subsequent years are for progressively larger and older fish. Survivors from cod tagged in 1997 would be at least 9 yrs old by 2002. In addition, the total landings have fluctuated since the fishery resumed, with highest reported landings in
1999. During 1999, estimates of exploitation for cod tagged in 3 K are extremely high (29-63\%), but dropped dramatically during 2000 and 2001 to $0-12 \%$. Cod tagged in 3 K in 2002 were quite heavily exploited (12-19\%) and the fishery was already underway when these tagged cod were released. The high estimates of exploitation for 1999 are associated with a catch of about 3,500 t within 3 K (Table 3A) where most of the tagged cod were recaptured. In 2000 and 2001, the reported catch for the inshore of 3 K dropped dramatically to about $1,500 \mathrm{t}-1,700 \mathrm{t}$, and further to only 600 t in 2002. A notable finding was that by 2002, none of the cod tagged in 3 K in 1999 were recaptured, either locally or in other regions. This is in marked contrast to cod tagged in other regions (i.e. $3 \mathrm{La}, 3 \mathrm{Lb}, 3 \mathrm{Lq}$ ) where tagged cod have continued to be recovered for at least 4-5 years.

Among cod tagged in Bonavista Bay (3La), estimates of exploitation were also highest for 1999, ranging from $6.0-18.4 \%$, with most values around $15 \%$. Note that two experiments conducted in 1997 gave similar estimates to those for cod released in 1999. Most estimates of exploitation for subsequent years were lower. In 2000, seven of twelve estimates of exploitation exceeded $10 \%$, whereas during 2001 most of the estimates were less than $10 \%$; the only exceptions were among recently tagged cod released in 2001 and 2002 where estimates were generally higher (4.5$24.5 \%$ ).

Among cod tagged in Trinity Bay (3Lb), estimates of exploitation for 1999 ranged from 3.5$13.2 \%$ and in general were slightly lower than those for neighbouring Bonavista Bay. In 2000 and 2001, most estimates of exploitation were between 5 and $15 \%$. The most notable finding was the apparent increase in estimates for 2002, particularly for cod tagged in Smith Sound. For 12 experiments conducted in Smith Sound, 5 had exploitation estimates exceeding 20\%. Note that most of the exploitation does not occur within Smith Sound itself; these cod migrate out of the sound are typically caught on either side of the Bonavista Peninsula and in Bonavista Bay (3Lb, see below).

Relatively small numbers of tagging experiments have been conducted in Conception Bay (3Lf) and along the eastern Avalon ( 3 Lj ) and most of the estimates have not exceeded $10 \%$. In contrast, cod tagged in St. Mary's Bay (3Lq) were more heavily exploited throughout 19992002, with 19 of 25 annual estimates exceeding $15 \%$. A significant portion of the exploitation of these cod occurs in the neighbouring stock area, particularly in Placentia Bay (3Psc)(see below).

## Spatial and temporal distribution of recaptures

Annual summaries of the distribution of recaptures, grouped by year and unit area of release, are given in Table 5 and for a subset of the experiments these are illustrated in a series of plots (Fig 4.). Cod tagged in northern 3 L and 3 K tend to remain in those regions, even after several years at liberty although there is considerable movement between $3 \mathrm{Ki}, 3 \mathrm{La}$, and 3 Lb even in the year of release. Similarly, cod tagged in Smith Sound tended to be recaptured northward on both sides of the Bonavista Peninsula and into Bonavista Bay (i.e. 3La) in the year of release and in subsequent years. A succession of annual taggings in Smith Sound has given similar results, with very few recaptures from more southerly areas. Returns from cod tagged in southern 3L (3Lf, 3Lj, and 3 Lq ) have tended to show substantial southerly movements into 3Psc.

## Conclusions

The results of the tagging study indicate that even with small inshore landings of typically only a few thousand tons or less from each unit area, estimates of exploitation rates for many of the tagging experiments are high. We have not specifically attempted to estimate inshore biomass at the time of the fishery in the present analysis, but the results suggest that the biomass available in each unit area would be, in general terms, in the tens of thousands of tons and mostly located in Trinity Bay and Bonavista Bay. In addition, cod are becoming increasingly scarce in the more northerly inshore area, particularly in 3 Kh and 3 Ki where landings and catch rates have dropped dramatically in recent years (Brattey et al. 2001a; Lilly et al. 2001). Catch rates and landings have also dropped in southern 3L, and there is strong evidence from the tagging experiments that catches from this area represent migrants from the neighbouring stock (NAFO Subdiv. 3Ps).

The overall conclusions from the trends in landings and analyses of the tagging data are: (1) the distribution of the stock is shrinking, particularly since 1999; (2) the northern coastal component of the stock is becoming increasingly concentrated around the Bonavista Peninsula and western Trinity Bay; (3) that exploitation rates, particularly among cod tagged in 3Lb, have increased to levels that are cause for concern.

## Acknowledgements

We thank the sentinel and commercial fishers and staff of the Fisheries Evaluation, Gadoids, and Commercial Sampling Sections of DFO Newfoundland Region for conducting the tagging experiments; C. George, D. Porter, P. Upward, and S. North collated the release and recapture information. We also gratefully acknowledge the assistance of Fisheries Officers and Observers in helping implement the tagging program, and thank the numerous fishers and plant workers for returning tags and recapture information. This study was funded by the DFO under the Strategic Science Fund program.

Table 4. Annual estimates of exploitation by experiment for Atlantic cod tagged in NAFO Divs. 3KL during 1997-2002. Recaptures were adjusted to account for reporting rate and releases were adjusted to account for tagging mortality, tag loss, and assumed natural mortality. Estimates for experiments where > 100 cod were tagged are shown. See text for details.
Shaded cells represent partial estimates as fishery in that year was already underway.

Table 5. Annual distribution of recaptures of cod tagged and released in NAFO Divs. 3KL during 1997-2002. Recaptures were adjusted by annual region and tag type-specific reporting rates obtained from a high-reward tagging study. Shaded cells give the percentage recaptured in the area of release. Values for 2002 based on tags received up to 5 Feb 2003.

Fig. 1. Locations where cod were tagged off eastern Newfoundland (NAFO Divs. 3KL) during April 1997-November 2002. The 200 m depth contour (grey line) is also shown.

Fig. 2. Distribution of cod landings along the inshore (north to south) of NAFO Divs. 3KL during 1998-2002. Total reported inshore landings are shown in the legend in the upper panel. Reported offshore landings have been low (<50 t) throughout 1998-2002.

Fig. 3. Tag retention rates for cod tagged with single and double t-bar anchor tags, based on return of 1884 double-tagged fish (from Cadigan and Brattey 2003).

Fig. 4. Annual distribution of recaptures.

Fig. 4. Cont'd.

Fig. 4. Cont'd.

[^0]:    * This series documents the scientific basis for the evaluation of fisheries resources in Canada. As such, it addresses the issues of the day in the time frames required and the documents it contains are not intended as definitive statements on the subjects addressed but rather as progress reports on ongoing investigations.
    * La présente série documente les bases scientifiques des évaluations des ressources halieutiques du Canada. Elle traite des problèmes courants selon les échéanciers dictés. Les documents qu'elle contient ne doivent pas être considérés comme des énoncés définitifs sur les sujets traités, mais plutôt comme des rapports d'étape sur les études en cours.

    Research documents are produced in the official language in which they are provided to the Secretariat.
