\* This series documents the scientific basis for the evaluation of fisheries resources in Canada. As such, it addresses the issues of the day in the time frames required and the documents it contains are not intended as definitive statements on the subjects addressed but rather as progress reports on ongoing investigations.

\* La présente série documente les bases scientifiques des évaluations des ressources halieutiques du Canada. Elle traite des problèmes courants selon les échéanciers dictés. Les documents qu'elle contient ne doivent pas être considérés comme des énoncés définitifs sur les sujets traités, mais plutôt comme des rapports d'étape sur les études en cours.

Research documents are produced in the official language in which they are provided to the Secretariat.

Les documents de recherche sont publiés dans la langue officielle utilisée dans le manuscrit envoyé au Secrétariat.

## ABSTRACT

This document updates the results of a multi-year tagging study of Atlantic cod (*Gadus morhua*), initiated in NAFO Subdiv. 3Ps in spring 1997, with about 8,000 additional cod tagged and released during April-June 2003. Since inception, a total of over 60,000 cod have been tagged with single, double, or high-reward t-bar anchor tags and released at various inshore and offshore sites off southern Newfoundland (3Ps) and 9,993 (16.5%) have been reported as recaptured to 30 September 2003. Estimates of exploitation for cod tagged in each region were computed using methods similar to those reported in our previous documents, but with minor modifications. Estimates of short-term tagging mortality, tag loss, and reporting rate were also obtained and are incorporated. Among cod tagged in Placentia Bay mean annual estimates of exploitation have declined from 33% in 1999 to 20% in 2002; however, some individual estimates remain quite high with six of 14 estimates exceeding 20% in 2002. Mean annual estimates for cod tagged in Fortune Bay have been fairly stable at 10% to 11%; however, cod tagged at Poole's Cove are being more heavily exploited than those off Pass Island in the outer reaches of Fortune Bay. Mean annual estimates for cod tagged in offshore areas remain consistently low (4% to 9% among cod tagged in 3Psd; 1-3% among those tagged in 3Psh). Some of the cod tagged in 3Psd (Burgeo Bank) are exploited in the neighbouring 3Pn4RS stock area, suggesting that stock mixing may extend to April in some years. As reported in previous analyses the exploitation estimates for 3Psh are extremely low given annual reported offshore landings ranging from 4,000 - 12,000 t during 1998-2002. Possible reasons include limited offshore tagging coverage, restricted distribution of offshore fishing effort, and low survival of cod offshore for tagging in deep (> 200m) water. In particular, there are substantial landings from areas on St. Pierre Bank (3Pse, 3Psf) that have generated few tag returns, suggesting that there are offshore stock components that have not been tagged. More extensive tagging coverage of the St. Pierre Bank area, particularly during fall, could improve the reliability of the exploitation estimates for the offshore regions.

## RÉSUMÉ

Nous présentons une mise à jour des résultats de l'expérience d'étiquetage pluriannuelle de la morue Atlantique (*Gadus morhua*) entreprise au printemps 1997 dans la sous-division 3Ps de l'OPANO, reposant sur quelque 8 000 autres morues étiquetées et remises à l'eau d'avril à juin 2003. Depuis le début de cette expérience, un total de plus de 60 000 morues ont été munies d'une marque à ancrage en T à récompenses simple, double ou élevée, puis remises à l'eau à divers points de la côte et de la haute mer dans la sous-division 3Ps de l'OPANO, située au sud de Terre-Neuve. Au 30 septembre 2003, 9 993 (16,5 %) de ces morues avaient été recapturées. Nous avons légèrement modifié les méthodes que nous avons utilisées dans nos études précédentes pour estimer les taux d'exploitation des morues étiquetées dans chaque secteur. Nous avons aussi fait des estimations du taux de mortalité à court terme due à l'étiquetage, du taux de perte d'étiquettes et du taux de déclaration des étiquettes récupérées. Dans le cas de la morue étiquetée dans la baie de Plaisance, les taux d'exploitation annuels moyens estimés ont diminué, passant de 33 % en 1999 à 20 % en 2002; certains demeurent toutefois assez élevés, 6 de 14 estimations dépassant 20 % en 2002. Variant entre 10 et 11 %, les taux pour la morue étiquetée dans la baie de Fortune sont demeurés relativement stables; par contre, la morue étiquetée dans l'anse Poole's est plus fortement exploitée que celle retrouvée au large de l'île Pass, située à l'entrée de la baie de Fortune. Les taux pour la morue étiquetée dans les eaux hauturières demeurent faibles sans exception (4 à 9 % pour la morue étiquetée dans 3Psd; 1-3 % pour celle étiquetée dans 3Psh). Un certain nombre de morues étiquetées dans 3Psd (banc Burgeo) sont capturées dans les eaux voisines de 3Pn4RS, ce qui donne à penser que les stocks se mélangent jusqu'en avril certaines années. Comme nous l'avons indiqué dans les analyses précédentes, les taux d'exploitation estimatifs pour 3Psh sont extrêmement faibles même si les débarquements annuels signalés de prises hauturières se situaient entre 4 000 et 12 000 t de 1998 à 2002. Cela pourrait être dû à une couverture d'étiquetage limitée des eaux hauturières, une distribution restreinte de l'effort de pêche hauturière et à un faible taux de survie de la morue étiquetée en haute mer (> 200 m). En particulier, les fortes prises récoltées dans certains secteurs du banc de Saint-Pierre (3Pse, 3Psf) ne contenaient que peu de morues étiquetées, ce qui donne à penser que des composantes hauturières du stock n'ont pas été étiquetées. Une couverture d'étiquetage plus vaste du banc de Saint-Pierre, en particulier durant l'automne, permettrait d'améliorer la fiabilité des estimations des taux d'exploitation dans les eaux hauturières.

## Introduction

A mark-recapture study of Atlantic cod (*Gadus morhua*), initiated in NAFO Subdiv. 3Ps during 1997, was continued during 2002-2003. The purpose of the study was to provide information on movement patterns of 3Ps cod as well as obtain estimates of exploitation rates on different components of the stock.

Annual estimates of exploitation are given for each tagging experiment conducted in 3Ps during 1997-2002 using the methods described in Brattey et al. (2003) with some minor modifications. This document also gives a summary of the spatial and temporal distribution of recaptures of tagged cod released in various regions of Subdiv. 3Ps during April 1997-June 2003 and reported as recaptured up to the end of September 2003. Previous results from post-moratorium cod tagging studies in 3Ps and adjacent areas are reported in Lawson et al. (1998), Brattey (1999, 2000), Brattey et al. (1999, 2002a), Robichaud and Rose (2001, 2002). Historical cod tagging studies (prior to 1994) in the Newfoundland Region are summarized in Taggart et al. (1995), Myers et al. (1996, 1997). Further analyses of the data from the post-moratorium cod tagging experiments are presented elsewhere (Brattey and Cadigan, in press; Cadigan and Brattey 1999a, b; 2000a, b; 2001, 2002, 2003; Lawson and Rose 2000; Lilly et al. 2001; Pope and Brattey 2001). Methods to estimate tagging mortality, and tag loss and reporting rates from the data reported herein are described in Brattey and Cadigan (in press) and Cadigan and Brattey 2003.

## Materials and Methods

Cod for tagging were captured with various gears (mostly hand-line and otter-trawl), measured (nearest cm) and tagged with one or two t-bar anchor tags inserted at the base of the first dorsal fin, and released. Experienced technicians conducted the tagging. Only cod  $\geq 45$  cm (fork length) that appeared healthy were tagged and each batch of cod typically consisted of individuals tagged with either single, double, or high-reward tags. The tags were uniquely numbered and bore a return address as well as the value of the reward (\$10 for one single, \$20 for two singles, or \$100 for high-reward). The tagging program was advertised extensively among those participating in the fishery. Details of the tagging experiments are summarised in Table 1. The number of cod tagged annually ranged from about 6,000 to 10,000. The sizes of tagged cod ranged from 45 to about 115 cm with mean lengths mostly in the 55-65 cm range. Approximately 56 tagging experiments have been conducted at various sites in 3Ps; most tagging has been conducted on spawning and pre-spawning aggregations at the head of Placentia Bay (3Psc), the head of Fortune Bay (3Psb), off Pass Island in the outer reaches of Fortune Bay, in the Burgeo Bank area (3Psa/d), in the Halibut Channel area (3Psh), and on one occasion off the north-western corner of St. Pierre Bank (3Psd)(Fig. 1).

Reported landings of cod from 3Ps (up to September 2003) and from neighbouring stock areas (3Pn4RS and 3KL) during recent years were extracted from the Statistics Branch catch database and are summarized to aid in the interpretation of tag returns.

## Estimation of exploitation rates

Development of the methods used to estimate exploitation rates is ongoing and the methods used here are similar to those described in Bratley and Healey (2003). Data from tag release and recaptures in 3Ps in 1997-2003 were used herein. As in previous analyses (Bratley and Healey 2003; Bratley et al. 2002a), we did not attempt to estimate population sizes using tag returns and commercial catches in this analysis, because typically some harvesting occurs in an area different from where fish were tagged; this makes it difficult to convert local catches to local population biomass. Methods to estimate cod biomass from tagging data and catches are presented elsewhere (Lilly et al. 2001; Pope and Bratley 2001; Cadigan and Bratley 2001, 2002).

Tag-induced mortality ( $\tau$ ) was estimated from experimental studies (Bratley and Cadigan, in press). An overall estimate of 0.12 was obtained, indicating that on average 12% of tagged cod succumbed “immediately” after tagging (a preliminary overall estimate of 0.13 was used in our previous documents). More detailed analysis has shown a significant seasonal tagging mortality effect which appears to be related to water temperature. Bratley and Cadigan (in press) found that tagging mortality was low (0.03) during spring (April-May) and higher (0.22) during late summer and fall (August-November); therefore, seasonal estimates of tagging mortality ( $\tau$ ) were used in the current analysis based on the month of release. The estimate of 0.03 was used for release months 1-6 and 0.22 for release months 7-12.

Our method of estimating reporting rate ( $\lambda$ ) is based on a high-reward tagging study, described in detail in Cadigan and Bratley (2003) and updated with recent recaptures. We used annual, region-specific estimates of reporting rate calculated from the high-reward tagging study; high-reward tags were assumed to have a reporting rate of 1.0.

Tag loss rates ( $\phi$ ) were estimated from a double-tagging study (see Cadigan and Bratley 2003), which showed that tag loss mostly occurred in the first 3-4 months after release with only minimal losses thereafter. We used the model proposed by Kirkwood (1981) to estimate tag loss rates

$$\phi_t = ((\beta_0 / (\beta_0 + \beta_1 t))^{\beta_0}; \beta_0, \beta_1 \geq 0$$

where  $t$  is the time at liberty. Cadigan and Bratley (2003) show that this model is more suitable than the proportional tag loss model proposed by Barrowman and Myers (1996). For each recapture year, we computed a time at liberty, which in the first year corresponds to the number of weeks between the median date of release of tagged fish and the median recapture date of tagged individuals in the year of release. For subsequent years, time at liberty is calculated by incrementing the number of weeks between the annual median dates of recapture.

Our analyses has shown that the rate of loss of tags depends on position and that the front tag of a double tagged fish is lost at a faster rate than the back tag; thus, there are three types of recapture from a double tagged fish: (the front tag only, the back tag only, or both tags). The tag loss model was used to compute the proportion of initial number of tags applied that were retained at the median date of recapture for each recapture year. This was done separately for each type of tag return.

To estimate exploitation annually, we tracked the numbers of fish available for capture in each year, accounting for tag loss and assumed natural mortality. The instantaneous rate of natural mortality ( $m$ ) assumed to be 0.2 per yr. The recaptures from each region ( $R$ ) were adjusted by the reporting rate ( $R^*$ ). In the initial year, we immediately removed those cod that die “instantly” due to tagging mortality. The estimates of loss are actually retention rates ( $\phi$ ) using Kirkwood’s model and apportioned by the time at liberty. Natural mortality ( $m$ ) was also apportioned by the time-at-liberty, i.e.  $e^{-m(t/52)}$

Let  $M(t)_{eff}$  denote the “effective” number of tagged fish available in year  $t$  prior to the fishery. After the fishery in year  $t$ , let  $next_t$  denote the number of tagged fish remaining. For fish having a single tag, in the year of release, if  $T_0$  is the number of fish tagged and released,

$$M(0)_{eff} = T_0 (1 - \tau) \phi_0 m_0,$$

and

$$next_0 = M(0)_{eff} - R_0^*.$$

In subsequent years,

$$M(t)_{eff} = next_{t-1} \delta_{L_t} \delta_{m_t}$$

where

$$\delta_{L_t} = \phi_t / \phi_{t-1} \text{ and } \delta_{m_t} = m_t / m_{t-1},$$

and

$$next_t = M(t)_{eff} - R_t^*.$$

Note that  $\delta_{L_t}$  and  $\delta_{m_t}$  are the proportion of additional tag loss and natural mortality to be removed from the available population. We use such ratios because the values of  $N$  and  $m$  are relative to the initial numbers of tagged cod.

For fish that are double-tagged and released, additional attention is required when adjusting the annual loss rates and computing the effective number of tagged fish remaining. For example, in any given year, a double-tagged fish may lose neither or both tags, or, could lose only the anterior or posterior tag. First, consider those fish that have retained both of the tags:

$$M(0)_{eff} = T_{D0} (1 - \tau) \phi_{A_0} \phi_{B_0} m_0$$

where  $\phi_{A_0}$  and  $\phi_{B_0}$  represent the tag retention of the anterior and posterior tags, and  $T_{D0}$  is the number of double-tagged fish released. After the fishery in the initial year,

$$next_0 = M(0)_{eff} - R_0^*.$$

In subsequent years,

$$M(t)_{eff} = next_{t-1} \delta_{L_t} \delta_{m_t}$$

where

$$\delta_{L_t} = \phi_{A_{-t}} \phi_{B_{-t}} / \phi_{A_{-(t-1)}} \phi_{B_{-(t-1)}} \text{ and } \delta_{m_t} = m_t / m_{t-1},$$

so the loss adjustment is made for both tags. After the fishery, we again have

$$next_t = M(t)_{eff} - R_t^*.$$

Double-tagged fish that lose one of their tags create two additional types of return to track: those that have the anterior tag only, and those that have the posterior tag only. In the first year, such individuals can only come from the double-tagged fish. However, in subsequent years, individuals with only the anterior tag come from two sources: those that had both tags in the previous year or those with only the anterior tag (which was retained) in the previous year. Thus, the number of individuals available to the fishery with the anterior tag only can increase over time. The identical situation exists for the individuals retaining the posterior tag. The expressions below indicate how we track fish that have the anterior tag (only) in place. In the year of release,

$$M(0)_{eff} = T_{D0} (1 - \tau) \phi_{A_{-0}} (1 - \phi_{B_{-0}}) m_0, \text{ and}$$

$$next_0 = M(0)_{eff} - R_0^*.$$

In subsequent years, (keeping in mind that individuals with the anterior tag come from two sources as described above),

$$M(t)_{eff} = next_{t-1} \delta_{L_{A_{-t}}} \delta_{m_t} + next_{D(t-1)} \delta_{L_{-D_t}} \delta_{m_t},$$

where

$$\delta_{L_{A_{-t}}} = \phi_{A_{-t}} / \phi_{A_{-(t-1)}}, \delta_{L_{-D_t}} = \phi_{A_{-t}} / \phi_{A_{-(t-1)}} \left( 1 - \phi_{B_{-t}} / \phi_{B_{-(t-1)}} \right) \text{ and } \delta_{m_t} = m_t / m_{t-1}.$$

Here,  $next_{D(t-1)}$  refers to the numbers of fish with both tags remaining available,  $\delta_{A_{-t}}$  is the tag-loss adjustment for individuals having the anterior tag only in the previous year, and  $\delta_{L_{-D_t}}$  is the tag-loss adjustment for double tagged fish in the previous year which have lost the posterior tag since the previous years fishery. Again we have

$$next_t = M(t)_{eff} - R_t^*.$$

Similar expressions are used to account for the numbers of fish available having the posterior tag only.

The exploitation rate  $\mu(t)$  in year  $t$  for each experiment is estimated by summing the adjusted number of recaptures across tag types and dividing by the summed numbers of each tag type available to the fishery, i.e.:

$$\mu(t) = \frac{\sum_k R_{t(k)}^*}{\sum_k M(t)_{eff(k)}}.$$

The subscript  $k$  represents available tag types at time  $t$ .  $M_{eff(k)}$  is the number of type  $k$  tags available at the time of the fishery in each year. Note that the annual median time at liberty is common across tag types within an experiment. Tagging experiments were conducted in consecutive years in some locations; thus multiple annual estimates of exploitation are given for some locations. Note that in some years tagged fish were released during the fishery and the first estimate of exploitation for these releases accounts for only a portion of the total exploitation in that year.

We also computed mean annual estimates of exploitation for each of the unit areas where fish were tagged. We used recaptures from the year of estimation and two preceding years in calculating these means, which were weighted by the numbers of tagged cod released (i.e. annual means for 2002 were based on recaptures from 2002, 2001 and 2000).

## Results

### Spatial and temporal distribution of cod landings

Reported monthly landings by unit area for 2002 are summarized in Table 2A. There were substantial landings (>1,000 t) in all unit areas, except 3Psg (91.8) and 3Psd (358 t) which is closed to directed cod fishing from November 15 – April 15. Highest landings (33-51% of the entire TAC) have come from Placentia Bay (3Psc) (Fig. 2) and reported landings from Placentia Bay in 2002 were about 1,000 ton less than in 2001 but still accounted for 33% of the overall catch compared to 39% in 2001. In the offshore, landings have mostly been highest in 3Pse/f/h, which includes the southern Halibut Channel and the northeastern and southeastern portions of St. Pierre Bank. Overall, the spatial distribution of landings in 2002 has been similar to that of 2001, although landings from 3Pse during 2002 were about 1,000 t higher than in 2001 and those for 3Psc less by a corresponding amount. Note that the catch by unit area reported herein includes French catches and therefore differs from that reported in Table 3 in Brattey et al. (2003).

At the beginning of the management year (April and May) inshore landings were low and came mostly from by-catch fisheries. There were substantial landings in all inshore unit areas during June -September 2002, particularly in Placentia Bay with reported landings of over 1,475 t in July alone. Landings were low in October in 3Psb, but peaked in 3Psa in October (327 t) and in 3Psc again in November (987 t). In the offshore, landings tended to be highest in Halibut Channel (3Psh) in late fall (November-December) and winter (January-March). There were also substantial landings from St. Pierre Bank (3Pse/f) during July-October.

Preliminary landings for the 2003 calendar year (Table 2A) show trends similar to those seen in 2002 with some notable exceptions. In particular, landings from Fortune Bay (3Psb) and Placentia Bay (3Psc) during September 2003 (1,113 t and 1172 t, respectively) are substantially

higher than those for the same month in 2002 (287 t and 352 t). Also, there are substantial landings from 3Psf (931 t) during January-February 2003 that are not evident in 2002.

Reported cod landings from adjacent management regions from 1998-2002 are summarized by unit area in Table 2B (Divs. 3KL) and Table 3C (3Pn4RS). The TAC's in these adjacent management units have been smaller than those in 3Ps (typically 3,000-9,000 t), and landings per unit area have ranged from a few hundred tons to over 1,000 tons, with the highest landings in 3Pn, 4R and 3La, 3Lb. A moratorium on directed cod fishing in these adjacent areas was re-introduced during 2003.

### **Numbers of recaptures**

A matrix of the numbers of tagged cod reported as recaptured annually (for all tag types combined) up to the end of September 2003 is given by tagging experiment in Table 3. As in previous years, there have been substantial numbers of recaptures from most inshore tagging experiments, particularly those conducted in Placentia Bay during spring. Offshore taggings (Halibut Channel, Hermitage Channel, Burgeo Bank, NW St. Pierre Bank) have tended to generate substantially fewer recaptures. Tags are still being returned from some experiments 6 years after release, although the numbers are quite low.

### **Exploitation estimates**

Annual estimates of exploitation (expressed as % of available numbers harvested) for each tagging experiment are summarized and grouped by unit area of release in Table 4. Tagging has been conducted at many locations in some unit areas; consequently, there are multiple estimates of exploitation for some areas, notably Placentia Bay (3Psc). Note that the values for preceding years may differ slightly from those reported in Brattey et al (2002a); this reflects slight change in the method of estimating reporting rate (see Table 6) and tag loss rate (see Brattey and Healey 2003), recovery of additional tags from previous years, and use of seasonal values for initial tagging mortality. Values for 2003 for all experiments are preliminary as the fishery was still in progress.

The number of cod tagged has been too low in the western portion of the inshore (i.e. 3Psa) to draw firm conclusions about exploitation of cod tagged in that region. Among cod tagged in two regions in Fortune Bay, estimates have tended to be low for cod tagged at Pass Island (4.6 - 10.7%) compared to those tagged at Poole's Cove (8.7 - 27.7%). Overall, the results indicate quite high exploitation of cod in the Poole's Cove area with 3 of 6 estimates for 2002 exceeding 22.0%. The overall annual means for 3Psb as a whole have been similar over the past three years at 10-11%.

Among cod tagged in Placentia Bay, estimates of exploitation for 2002 have been variable and generally higher for more recently tagged cod (1998 onwards). Highest estimates (typically 25-45%) are seen during 1999 and 2000 when both the overall TAC and landings in Placentia Bay were highest (see Fig. 2). Estimates of exploitation in 2002 for cod tagged in Placentia Bay are slightly lower than those observed in the previous three years (1999-2001) when estimates for most experiments exceeded 20% and the annual means ranged from 26% to 33%. Exploitation

seems to be declining in Placentia Bay with annual means declining from 33% in 1999 to 20% in 2002. This decline follows the reduction in landings seen over the past four years (see Fig. 2). However, note that not all of the exploitation of these cod occurs in Placentia Bay itself (see Table 5) and recent reductions in catch from the cod fishery in adjacent 3KL may also have lowered these estimates. Nonetheless, the 2002 estimates for 6 of 14 experiments conducted in 3Psc since the fall of 1998 remain high and exceed 20% (Table 4). The estimates for cod tagged prior to the fall of 1998 are based on very few recaptures (<5) and are consistently low; this may reflect growth and reduced selection of the remaining tagged fish from these experiments; most of these fish may have grown beyond the optimum selection size of gillnets which account for most of the catch. These recaptures were therefore not included when calculating annual means.

Among cod tagged in 3Psd since 1998, estimates of exploitation have been much lower than those for cod tagged inshore, ranging from 1.0 to 9.8% for individual experiments. The annual means have also been similar, ranging from 5% to 9%. Cod tagged in Halibut Channel (3Psh) have consistently shown lowest estimates of exploitation, with annual means typically around 1-3% and little variation among experiments in spite of substantial landings, particularly in 2000 (see Fig. 2).

### **Spatial and temporal distribution of recaptures**

Annual summaries of the distribution of recaptures, grouped by unit area and year of release, are given in Table 5; in addition, plots showing the annual distribution of recaptures (only for tags where exact recapture positions were reported) by unit area of release are shown in Figs. 3A-3E.

Cod have been tagged offshore in 3Psd (Hermitage Channel and the southern edge of Burgeo Bank) in April in five of the previous six years (Fig. 3A); the exception was 2000 when no significant aggregations were located. Many of these tagged cod have dispersed widely from the tagging area with recaptures extending west and northward into 3Pn-4RS as far north as the Strait of Belle Isle (4Ra) within 3 months of release. Others migrated inshore and eastward along the south coast of Newfoundland into unit areas 3Psa, 3Psb, and 3Psc, and more rarely into southern 3L. The proportion of recaptures from 3Pn-4RS relative to 3Ps has varied annually and appears to be higher from the 1998 and 2001-2002 releases compared to the 1999 releases. The 2001-2003 taggings in 3Psd were conducted somewhat later in April to coincide with the DFO research vessel survey in that area. A substantial proportion of the recaptures from these experiments have come from 3Pn-4RS, suggesting that mixing may extend to mid-April in some years; however, the proportions of cod from each stock present in mid-April remains difficult to determine. In addition, the directed cod fishery in 3Pn-4Rs was closed in 2003 making comparison with previous years more difficult. Few of the cod tagged in Burgeo Bank have been recaptured on the southeast corner of St. Pierre Bank, or in Halibut Channel, in spite of substantial landings, suggesting little inter-mixing between cod tagged in these two offshore regions during April. The lack of recaptures close to the tagging site in 3Psd can be attributed at least partly to this region being closed to directed cod fishing from November-April since 1998.

Most cod tagged near Pass Island and Poole's Cove, Fortune Bay, show strong inshore residency even among recaptures taken 4-5 years later, with most recoveries coming from within Fortune Bay or eastward into neighbouring Placentia Bay (Fig. 3B). There is little evidence of westward movement of these cod with only a few recaptures from 3Pn-4RS especially from experiments

conducted later in spring (late May). These experiments may have included some migrant fish from areas to the west. Small proportions of cod tagged in Fortune Bay have also been recovered from more distant regions such as southern 3L, offshore 3Ps, and 3Pn4RS, but in general there are no strong indications of any progressive dispersal away from the tagging region over time.

A single experiment involving only 57 cod tagged in 3Psa has generated a small number of inshore recaptures in 3Ps west of the Burin Peninsula, with one offshore recapture in Halibut Channel (Fig 3C).

Cod have been tagged offshore in Halibut Channel (3Psh) during April in five consecutive years. (see Fig. 3D and Table 5). Recaptures have come mainly from three areas: (1) the slope edge at the bottom of Halibut Channel close to the area of release (3Psh), (2) shallow water on the south-east corner of St. Pierre Bank in unit areas (3Psf and 3Psh), or (3) inshore in Placentia Bay and around the Avalon Peninsula (3Psc and 3Lj/q/f). A few cod tagged in this region have been reported as recaptured in 3NO where the directed fishery for cod is still under moratorium, and single recaptures have been reported from 3K and 4R. Overall, the distribution of recaptures has been consistent for 5 years, although substantially fewer recaptures have been obtained from the 2000 and 2001 releases in Halibut Channel relative to those released in 1998 and 1999. Also, it is notable that there have consistently been few recaptures from the western portion of the inshore of 3Ps (i.e. 3Psa and 3Psb) in spite of substantial landings (see Fig. 2).

Cod tagged in Placentia Bay (Fig. 3C) have mostly been recaptured inshore within Placentia Bay or in neighbouring Fortune Bay. Typically over 80% of the recoveries have come from within Placentia Bay itself, even 5-6 years after tagging (Table 5). In each year, small proportions of recaptures have come from southern 3L, particularly in 1999, and more rarely northern 3L (i.e. 3La, 3Lb) or 3K. Most tagging experiments in Placentia Bay in spring have resulted in a small number of recaptures clustered at the slope edge at the bottom of the Halibut Channel, or scattered across St. Pierre Bank. However, the number of reported offshore recaptures from Placentia Bay tagging has been small in spite of substantial offshore landings (see Table 2A, Fig. 2).

Cod tagged on the NW edge of St. Pierre Bank have mostly been recovered only short distances away eastward on St. Pierre Bank, or inshore in Placentia Bay (Fig. 3A). There are no recoveries of these cod from 3Pn4RS, in contrast to those tagged in the Burgeo Bank-Hermitage Channel area about 25 miles to the northwest (see Fig. 3A).

## Discussion

The updated results described herein are generally similar to those given in our previous analyses (Bratney et al. 2002a), and again show limited mixing of cod from different portions of the 3Ps stock area as well as higher exploitation of adult cod in the inshore. There are indications of strong inshore residency among fish tagged in spring in Fortune Bay and Placentia Bay. These fish appear to disperse along the inshore during summer, particularly in an easterly direction, with their distribution extending into 3L in some years. There appears to be limited offshore movement of these cod with only a few offshore recaptures even several years after release. These inshore sub-components, particularly in Placentia Bay, are supplemented during late spring, summer, and fall by seasonal migrants from offshore areas. The tagging shows that the

inshore catch comprises a mixture of cod that includes inshore fish as well as migratory offshore cod from Burgeo Bank, St. Pierre Bank, and the Halibut Channel. In contrast, the offshore catch (3Ps/e/f/g/h) appears to be comprised mainly of fish that reside on St. Pierre Bank and in Halibut Channel throughout the year.

Results from tagging in the Burgeo area suggests that there may be mixing of 3Ps cod with those from 3Pn4RS even as late as mid-April, suggesting that spring research vessel survey catches may include some non-3Ps fish. However, the extent of mixing appears to vary annually and the precise stock affinity of these fish remains difficult to determine (Campana et al. 1999; Chouinard, 2000; Bérubé and Fréchet 2001).

Although the tagging in the Burgeo area suggests that there may be mixing with Gulf cod even as late as mid-April in some years, our estimates of exploitation for cod tagged in this region are low and do not suggest cod in the Burgeo Bank area at that time, irrespective of their stock affinity, have been heavily exploited. In addition, catches from the "mixing" area itself have been low in recent years due to seasonal closures and the switch from a competitive fishery to individual quotas. Reported commercial landings from 3Psa/d combined during November-April 2002/2003 were only 260 t. These data suggest that potential removals of 3Pn4RS cod from this area, particularly in 2001 and 2002, are relatively small and likely to have little influence on the dynamics of that stock.

In contrast, cod tagged in Placentia Bay have been more heavily exploited and there is a concentration of fishing effort in this portion of the stock area, particularly in July and again in November-December in most years. Local fishers have reported that the abundance of cod in Placentia Bay in late fall increased considerably during the moratorium. Catch rates in Placentia Bay declined after the fishery reopened in 1997, but have remained similar over the past 3 years (Bratley et al. 2002b), suggesting that current exploitation rates are preventing local rebuilding of this component of the stock. Our estimates of exploitation for cod in Placentia Bay during 2002 (20%) tend to be lower than those for the preceding three years and correlate well with the reduction in landings both overall and from within Placentia Bay. However, catch rate indices from sentinel and logbooks for the <35' sector have remained low but largely unchanged for the past three years. For this local stock to rebuild it appears that further reductions in exploitation (and/or better recruitment) would be required. In contrast, catch rate indices (sentinel line-trawl and under 35" line-trawl) for Fortune Bay (3Psb) as a whole have been quite stable in recent years (see Bratley et al 2003). Our tagging data suggest that overall exploitation among cod tagged in Fortune Bay has been reasonable, although some high estimates have been obtained for the inner reaches of Fortune Bay.

The estimates of exploitation for the offshore areas in 3Ps are much lower than those for other regions, in spite of substantial offshore landings ranging from 4,000 - 12,000 t per annum during 1998-2002 (Fig 2). As in the previous analyses (Bratley et al. 2002a) there are concerns that the estimates for the offshore may be too low. Possible reasons include, estimates of reporting rate that are too high, limited tagging coverage (both spatial and temporal), restricted distribution of fishing activity in the offshore, and possibly lower survival of fish caught for tagging offshore in deep (>200m) water (see Bratley and Cadigan, in press). There have been substantial landings in some portions of the offshore where little or no tagging has been conducted (i.e. 3Pse/f, see Table 2) suggesting that there are offshore stock components that contribute significantly to the fishery that have not been tagged. More extensive tagging coverage, particularly on St. Pierre

Bank during fall, would clearly be beneficial to determine the origins of these cod and provide more reliable estimates of offshore exploitation.

## Acknowledgements

We thank the sentinel and commercial fishers and staff of the Fisheries Evaluation, Gadoids, and Commercial Sampling Sections of DFO Newfoundland Region for conducting the tagging experiments; graduate students working under the chair of Fisheries Conservation, Memorial University, conducted some of the tagging in 1997. Clyde George, D. Porter, P. Upward, and S. North collated the release and recapture information. We also gratefully acknowledge the assistance of Fisheries Officers and Observers in implementing the tagging program, and thank the numerous fishers and plant workers for returning tags and recapture information. This study was funded by the DFO under the Strategic Science Fund program.

\* tags received up to 30 Sept. 2003

Table 4. Annual estimates of exploitation (harvest rates) by experiment for cod tagged in NAFO Subdiv. 3Ps during 1997-2003. Recaptures were adjusted to account for reporting rate and releases were adjusted to account for tagging mortality, tag loss and assumed natural mortality. Shaded cells represent estimates for experiments conducted during the fishing season and account for only a portion of exploitation in the year of release. Boxed cells indicate values used to compute annual means for each area of release. See text for further details.

\* based on recorded catch and tags received up to 30 September 2003

Table 5. Annual distribution of recaptures of cod tagged and released in various regions of NAFO Subdiv. 3Ps during 1997-2003. Recaptures were adjusted by region-specific reporting rates obtained from a high-reward tagging study. Shaded cells give the percentage recaptured in the area of release. Values for 2003 are based on tags received 30 September 2003.

| Release area | Release Year | Number tagged | Recapture year | Adj. nos. recap'd | % of annual recaptures |           |             |             |             |            |            |           |             |            |            |        |        | UNK |

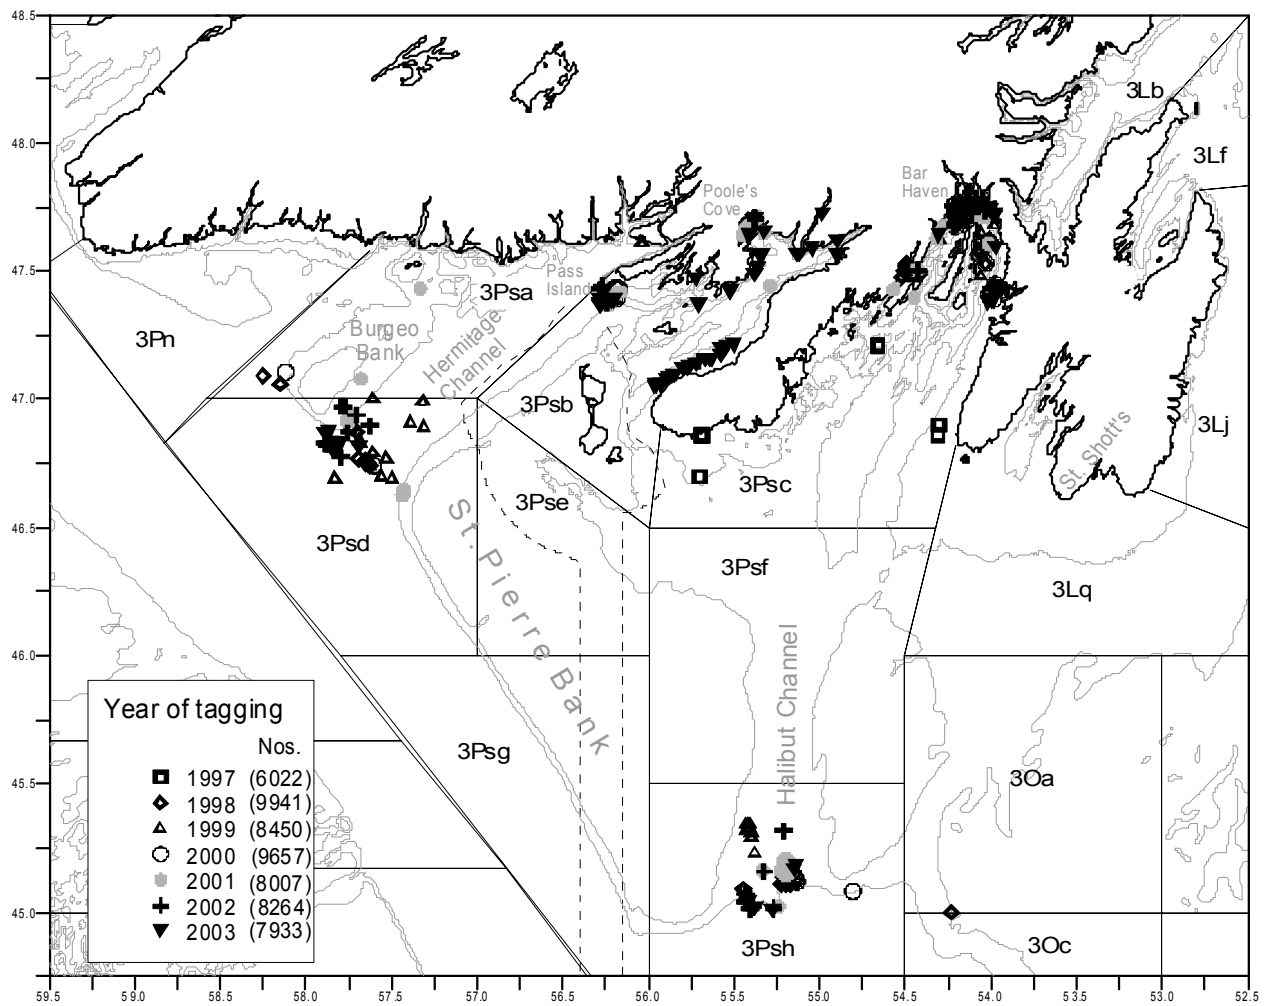

Fig. 1. Locations and total numbers of cod tagged each year off southern Newfoundland during 1997-2002, boundaries of unit areas, 100 m and 200 m depth contours (grey lines), and boundary of French economic zone (dashed line).

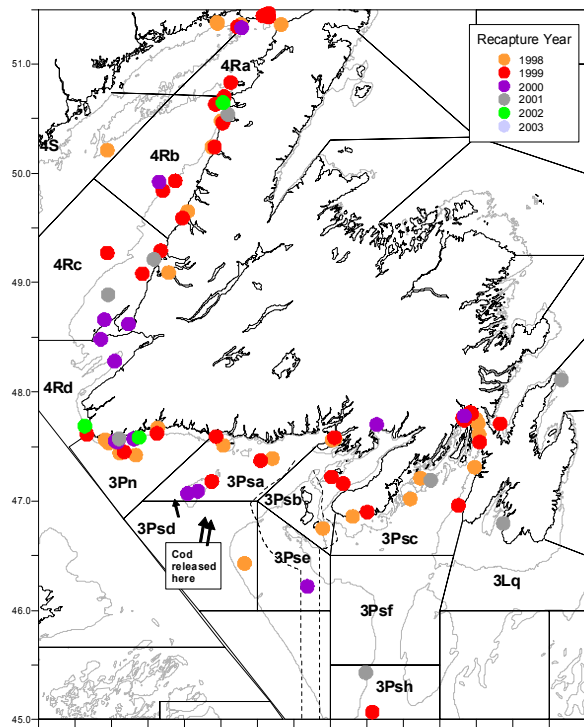

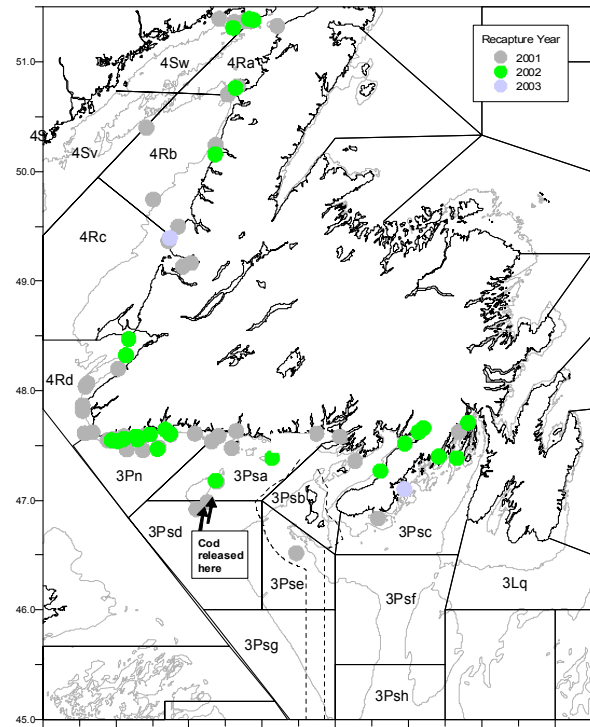

Fig. 2. Annual reported landings of cod by unit area from NAFO Subdiv. 3Ps during 1997-2002.

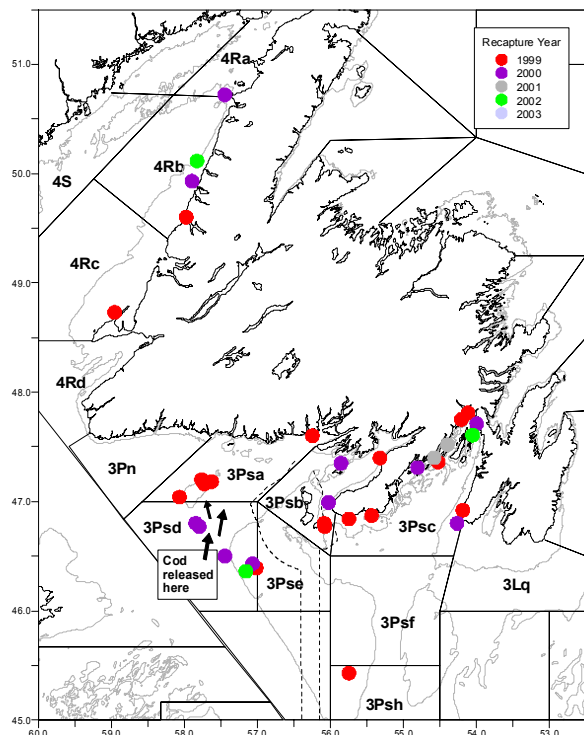

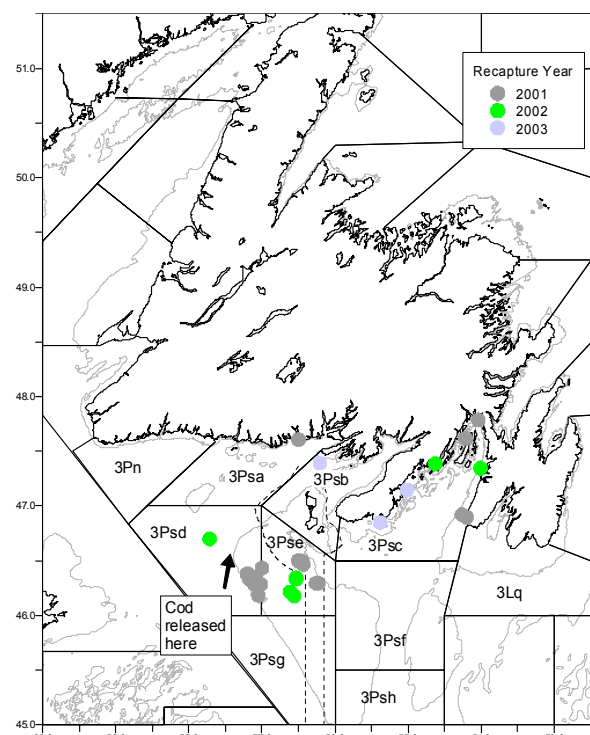

Reported recapture positions for cod tagged and released in Hermitage Channel - Burgeo Bank during 5-7 April 1998 (N=1352).

Reported recapture positions (dots) for cod tagged and released off Burgeo Bank-Hermitage Channel during 15-17 April 2001 (N=999).

Reported recapture positions (dots) for cod tagged and released in Hermitage Channel - Burgeo Bank during 4-7 April 1999 (N=464).

Reported recapture positions for cod tagged and released off northwestern St. Pierre Bank during 16-17 April 2001 (N=666).

Fig. 3A. Recaptures of cod tagged in 3Psd during April (1998, 1999, 2001-2003).

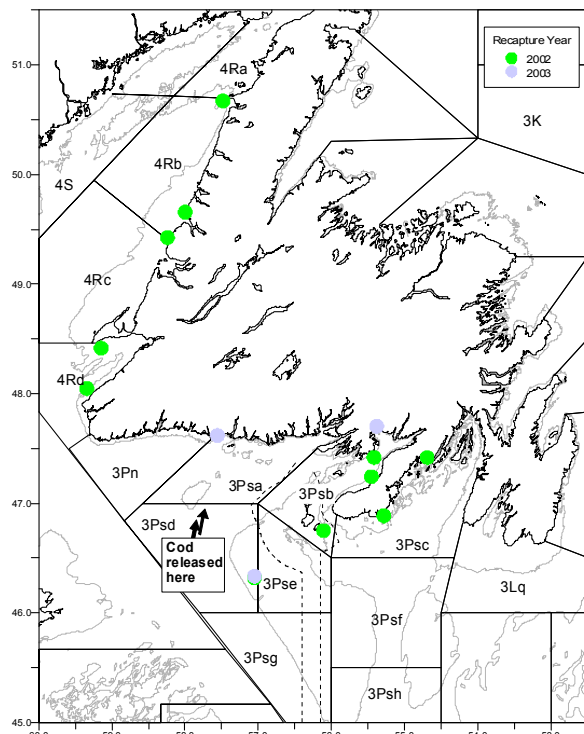

Fig. 3A. Recaptures of cod tagged in 3Psd during April (1998,1999, 2001-2003).

Reported recapture positions for cod tagged and released in 3Lb (south side Fortune Bay) during 17-27 June 2003 (N=630).

Reported recapture positions for cod tagged and released in 3Lb (off Pass Island) during 14-15 Apr 2003 (N=1481).

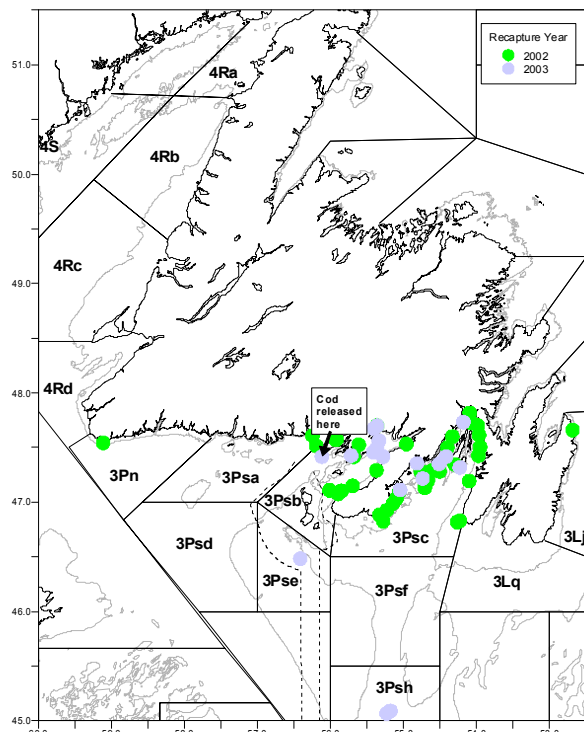

Reported recapture positions for cod tagged and released in 3Lb (north side Fortune Bay) during 16-22 June 2003 (N=1384).

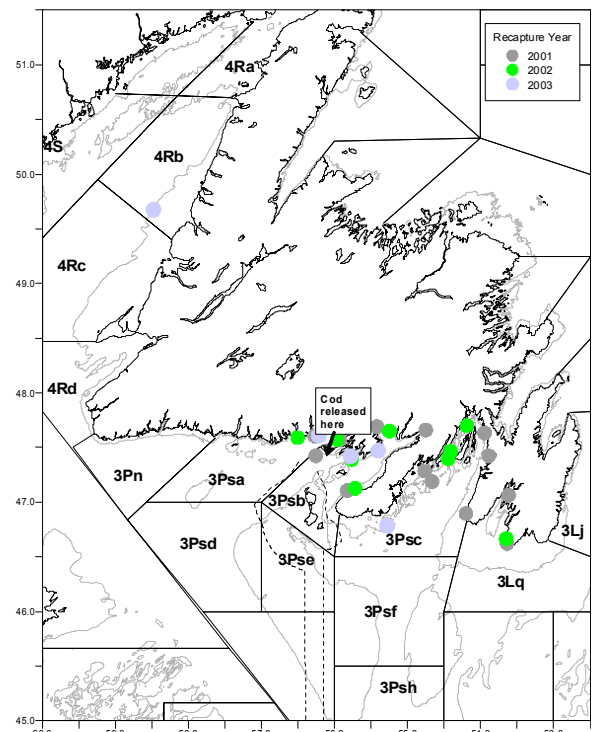

Reported recapture positions for cod tagged and released in 3Lb (off Grand Bank) during 18 June 2002 (N=138).

Fig. 3B. Recaptures of cod tagged in 3Psb during April-June (1998-2003).

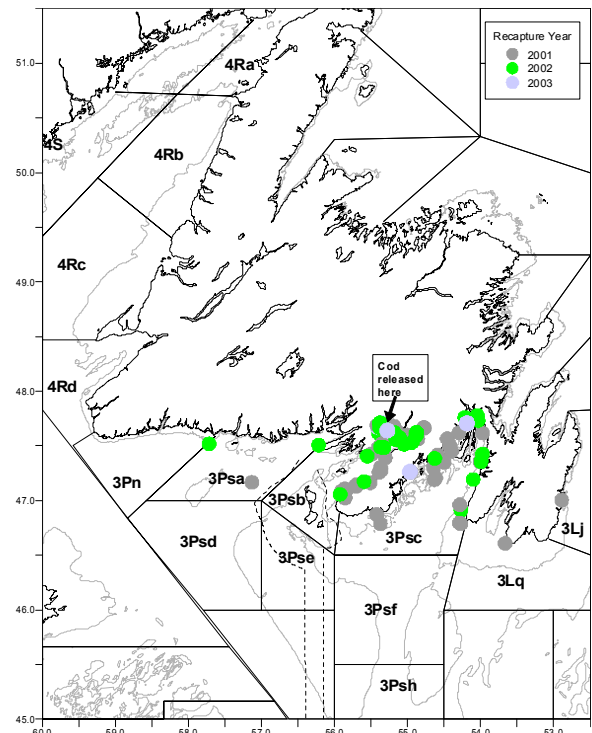

Reported recapture positions for cod tagged and released in 3Lb (off Pass Island) during 13-14 Apr 2002 (N=1792).

Reported recapture positions for cod tagged and released in 3Lb (off Pass Island) during 18 Apr 2001 (N=477).

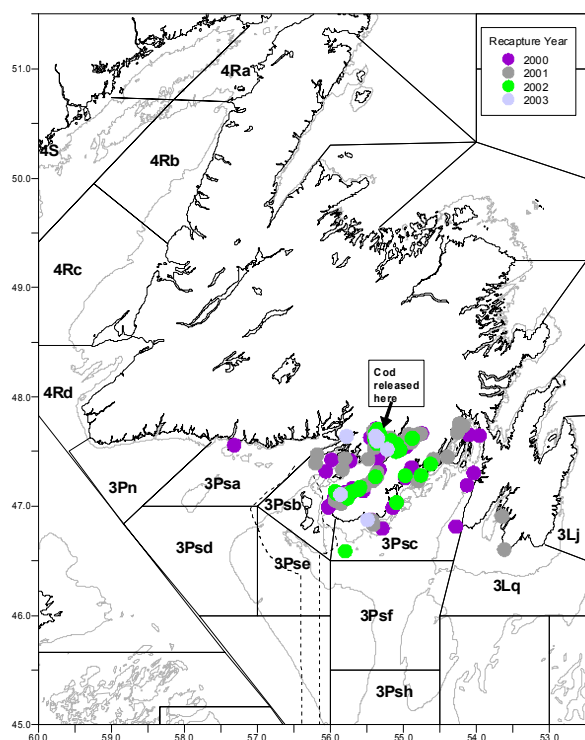

Reported recapture positions for cod tagged and released in 3Lb (off Poole's Cove) during 8-10 Jan 2002 (N=408 and N=223).

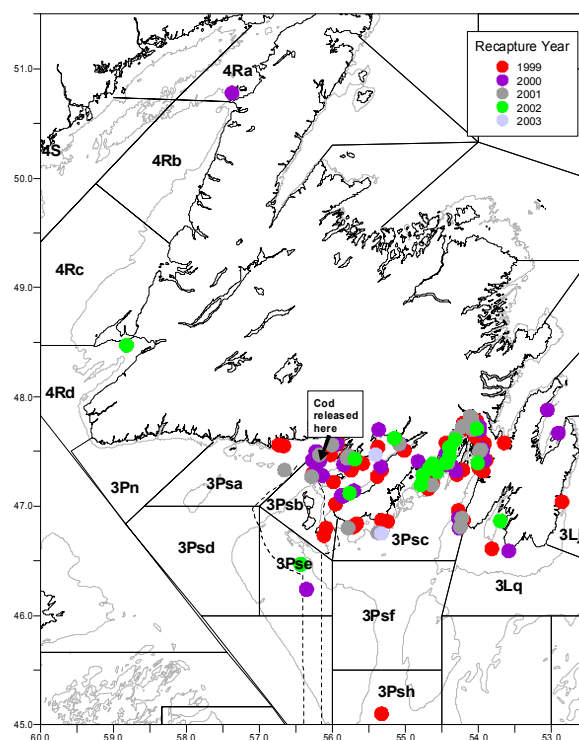

Reported recapture positions for cod tagged and released in 3Lb (off Poole's Cove) during 9-11 Jan 2001 (N=200 and N=388).

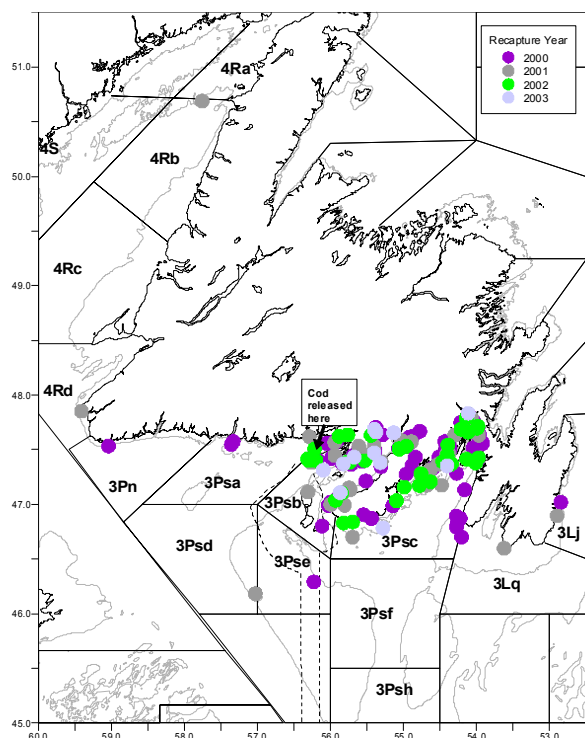

Fig. 3B. Recaptures of cod tagged in 3Psb during April-June (1998-2003).

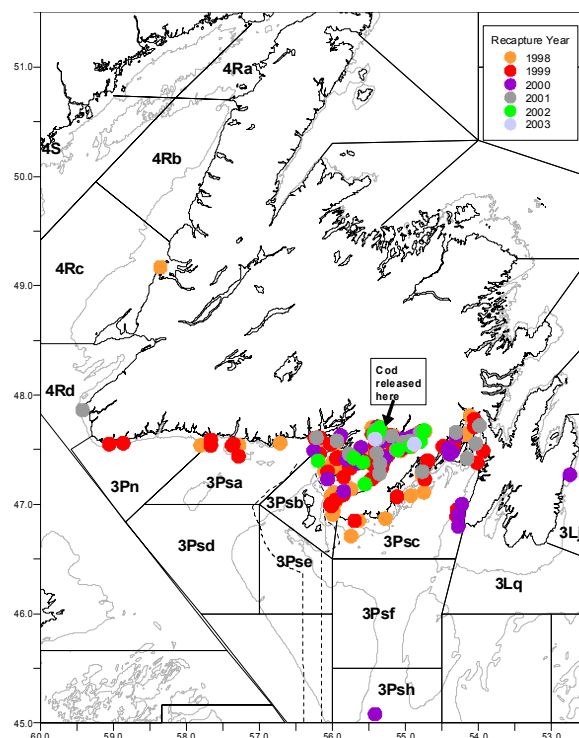

Reported recapture positions for cod tagged and released in 3Lb (off Poole's Cove) during 17-19 Apr 2000 (N=752).

Reported recapture positions for cod tagged and released in 3Lb (off Pass Island) during 8 Apr 1999 (N=1293).

Reported recapture positions for cod tagged and released in 3Lb (off Pass Island) during 5-7 Apr 2000 (N=1665).

Reported recapture positions for cod tagged and released in 3Lb (off Poole's Cove) during 20-29 May 1998 (N=938).

Fig. 3B. Recaptures of cod tagged in 3Psb during April-June (1998-2003).

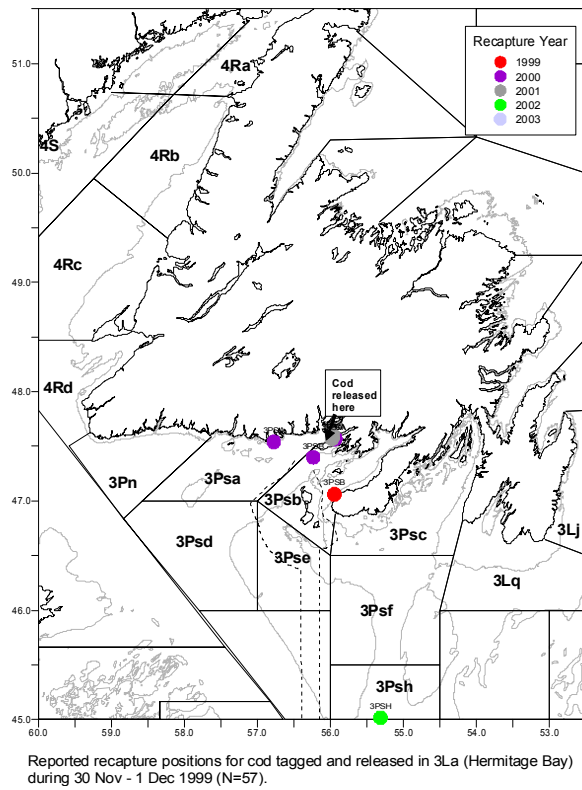

Fig. 3C. Recaptures of cod tagged in 3Psa during Nov-Dec 1999.

Fig. 3D. Recaptures of cod tagged in 3Psh during April 1998-2003.

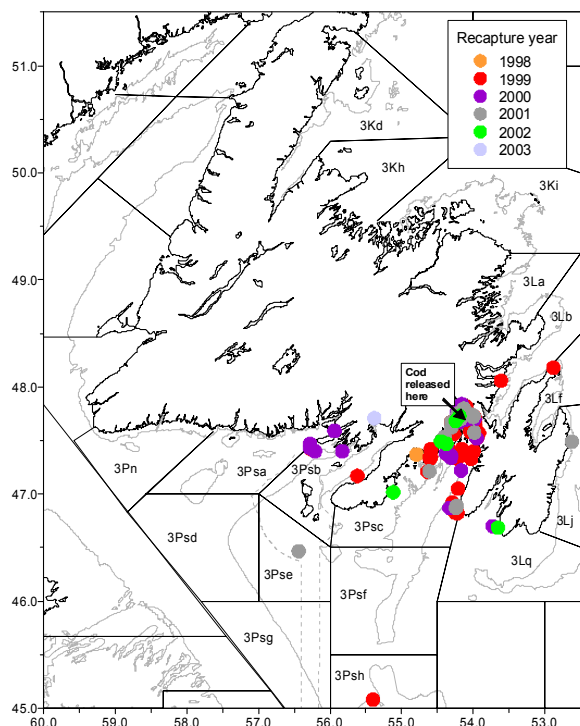

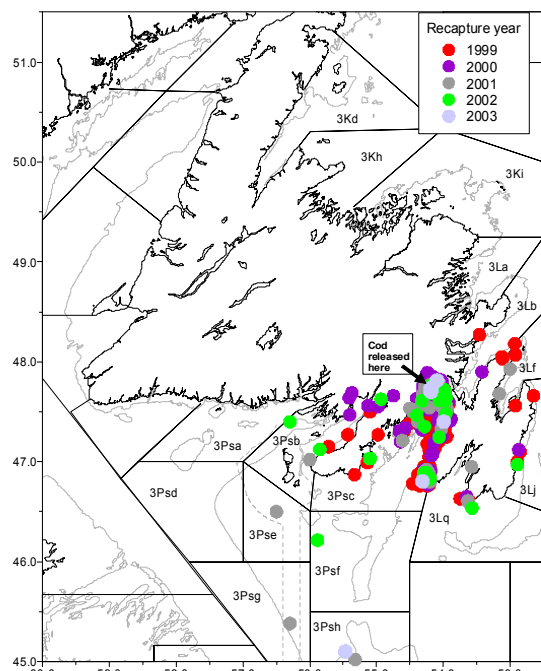

Fig. 3D. Recaptures of cod tagged in 3Psh during April 1998-2003.

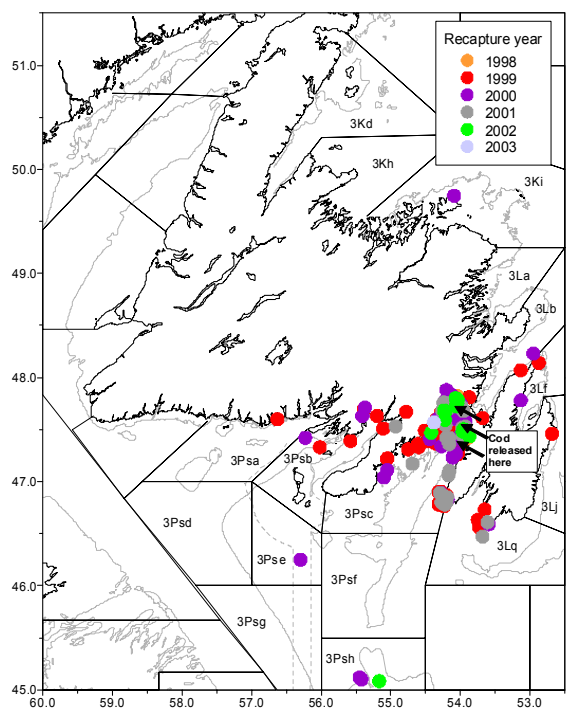

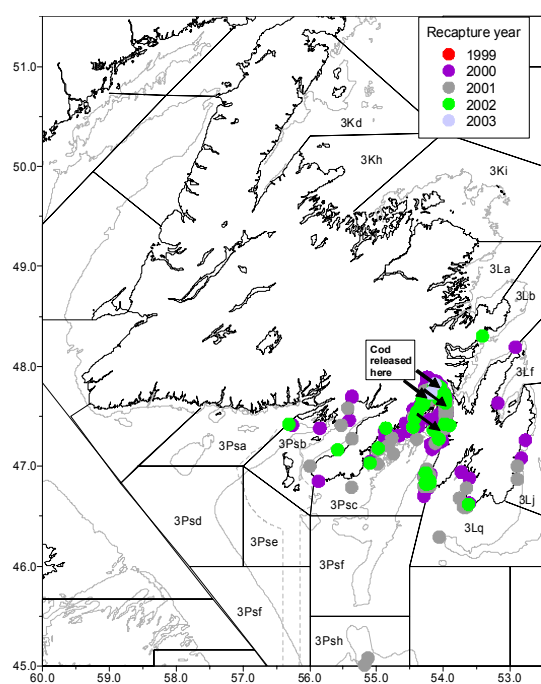

Reported recapture positions for cod tagged and released in 3Psc (Eastern Channel) during 19-24 October 1998 (N=511).

Reported recapture positions for cod tagged and released in 3Psc (inner Placentia Bay) during 29 April - 7 May 1999 (N=2494).

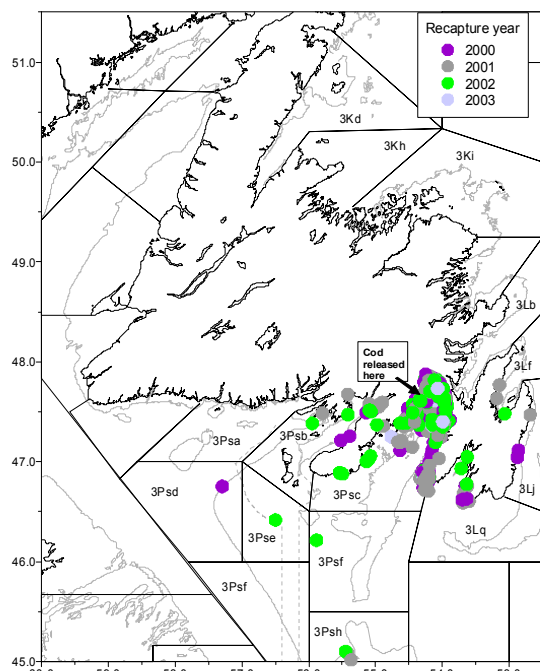

Reported recapture positions for cod tagged and released in 3Psc (Eastern Channel) during 17-22 October 1998 (N=883).

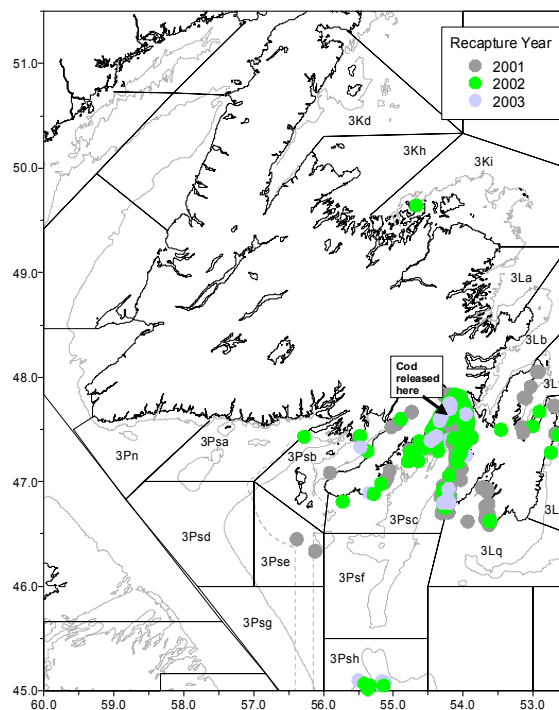

Reported recapture positions for cod tagged and released in 3Psc (inner Placentia Bay) during 8-17 Nov 1999 (N=2152).

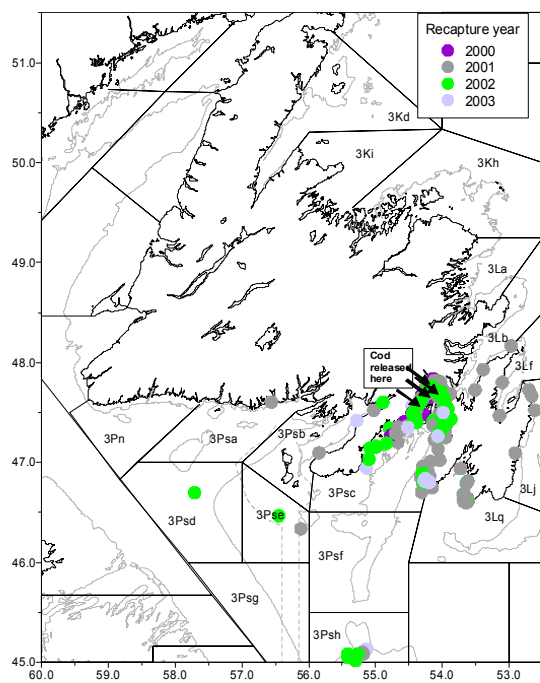

Fig. 3E. Recaptures of cod tagged in 3Psc during October 1998-May 2003.

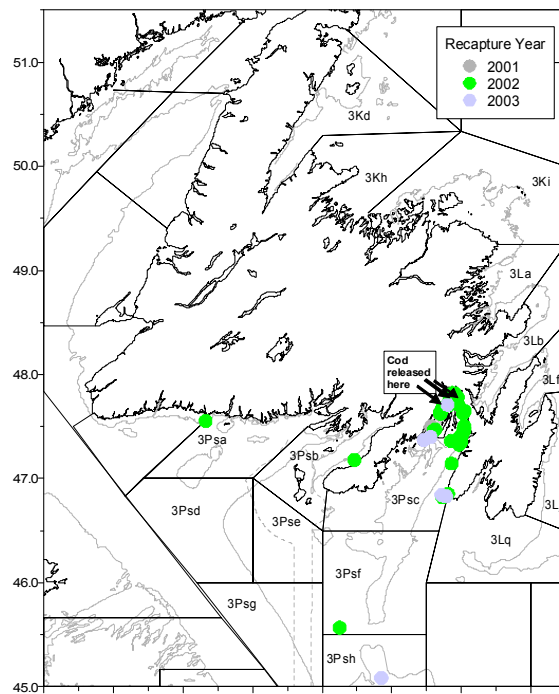

Reported recapture positions for cod tagged and released in 3Psc (inner Placentia Bay) during 26 April - 6 May 2000 (N=2494 and N=528).

Reported recapture positions for cod tagged and released in 3Psc (inner Placentia Bay) during 28 April - 7 May 2001 (N=1704 and N=2273).

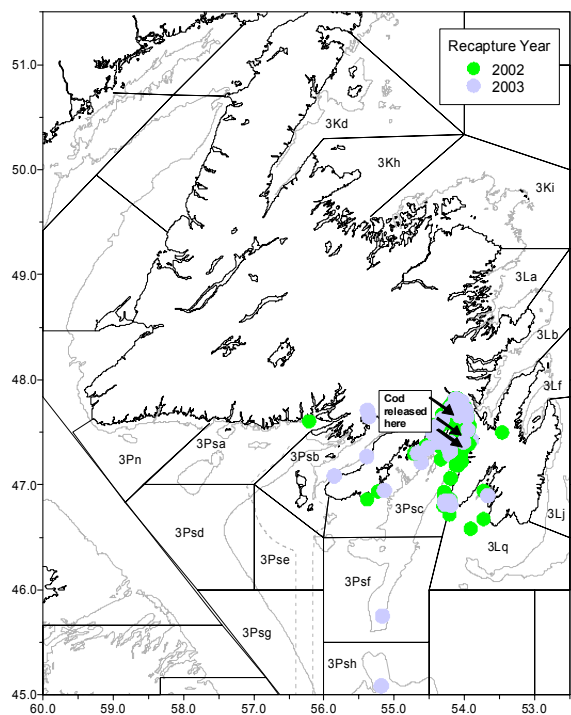

Reported recapture positions for cod tagged and released in 3Psc (inner Placentia Bay) during 5-15 Nov 2000 (N=1165, N=792 and N=1212).

Reported recapture positions for cod tagged and released in 3Psc (inner Placentia Bay) during 22 Nov 2001 (N=350).

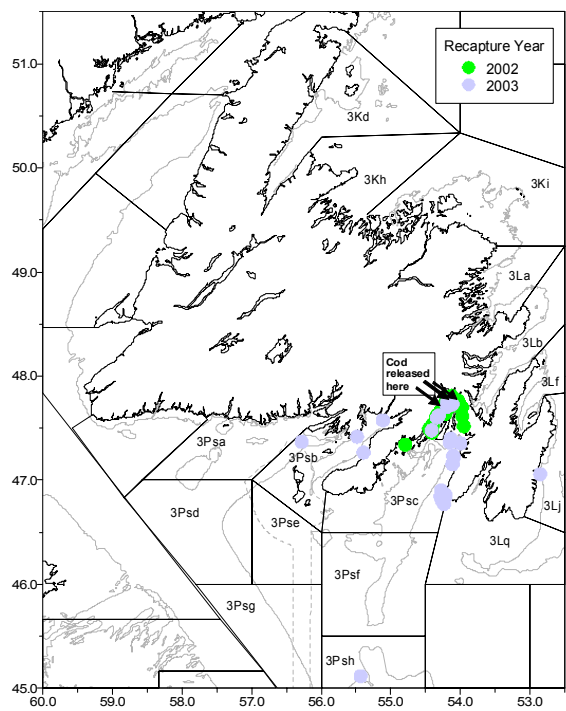

Fig. 3E. Recaptures of cod tagged in 3Psc during October 1998-May 2003.

Reported recapture positions for cod tagged and released in 3Psc (inner Placentia Bay) during 27 April - 7 May 2002 (N=1832 and N=1399).

Reported recapture positions for cod tagged and released in 3Psc (inner Placentia Bay) during 28 Apr.-11 May 2003 (N=3,427).

Reported recapture positions for cod tagged and released in 3Psc (inner Placentia Bay) during 12-18 Nov 2002 (N=1,676).

Fig. 3E. Recaptures of cod tagged in 3Psc during October 1998-May 2003.
