# 2004 Evaluation of 4VWX Herring 

## Évaluation des stocks de hareng dans 4VWX en 2004

#### Abstract

Landings in the southwest Nova Scotia/Bay of Fundy spawning component in 2003 ( $89,360 \mathrm{t}$ ) were $12,000 \mathrm{t}$ higher than the previous year and the highest since 1993. Acoustic surveys in 2003 continued to show a spawning stock biomass (SSB) of approximately 500,000t but there has been deterioration in the state of the stock. The 2003 catch was dominated by age 2 (by number) and 3 (by weight) and there is an absence of old fish in the population, with increased targeting of juveniles by the fishery. SSB on both Trinity Ledge and Seal Island spawning areas remain well below historical levels. While recent catches have been consistent with the survey, assess, fish protocol of less than $20 \%$ of surveyed biomass, catch at age and the rapid decline of year-classes indicates that total mortality may be considerably higher. There has been insufficient progress towards defined conservation objectives in recent years.

Landings for 2003 in the offshore Scotian Shelf banks spawning component (less than 1,000t) were the smallest since the fishery was reactivated in 1996. The 2003 fishery was dominated by the 1998 year-class (age 5). However, bottom trawl research survey catches of the past six years have been the highest on record and herring were widely distributed on banks west of Sable Island.

Biomass estimates from acoustic surveys of the major coastal Nova Scotia spawning components were higher for all surveyed areas in 2003 with large increases for the Little Hope, Eastern Shore and Glace Bay areas. The Bras d'Or lakes fishery was closed in 2003 with only research gillnet sampling to document the age distribution.

There was a further drop in landings in the traditional New Brunswick weir and shutoff juvenile herring fishery to 9000t - the lowest since 1983.

## RÉSUMÉ

En 2003, les débarquements de reproducteurs capturés dans le secteur sud-ouest de la Nouvelle-Écosse/baie de Fundy se sont chiffrés à 89360 tonnes, soit 12000 t de plus que l'année précédente, un sommet depuis 1993. D'après les relevés acoustiques effectués en 2003, la biomasse du stock reproducteur se chiffre encore à environ 500000 t , mais l'état du stock s'est détérioré. Les prises de 2003 comprenaient principalement des poissons de 2 ans (en nombre) et de 3 ans (en poids). La population de harengs ne compte aucun vieux poisson puisque les juvéniles sont de plus en plus ciblés par la pêche. La biomasse du stock reproducteur dans les frayères du récif de la Trinité et de l'île Seal demeure très inférieure à ses niveaux historiques. Quoique les prises récentes aient été conformes au protocole de relevé, d'évaluation et d'exploitation de moins de $20 \%$ de la biomasse observée dans le relevé, les prises selon l'âge et la baisse rapide de l'effectif des classes d'âge révèlent que la mortalité totale pourrait être considérablement plus élevée. Au cours des dernières années, les progrès vers les objectifs de conservation ont été insuffisants.

En 2003, les débarquements de reproducteurs capturés sur les bancs du large du plateau néo-écossais se sont chiffrés à moins de 1000 t , le plus bas niveau depuis la réouverture de la pêche en 1996. Les prises de 2003 comprenaient principalement des harengs de 5 ans (classe d'âge de 1998). Cependant, dans les relevés de recherche au chalut de fond des six dernières années, les prises ont atteint des sommets records et le hareng était très répandu sur les bancs situés à l'ouest de l'île de Sable.

Les estimations de la biomasse effectuées à partir des résultats des relevés acoustiques des principaux groupes de reproducteurs des côtes de la Nouvelle-Écosse ont été plus élevées pour chacune des zones ayant fait l'objet d'un relevé en 2003, des hausses importantes ayant été enregistrées dans les secteurs de Little Hope, Eastern Shore et de Glace Bay. La pêche dans les lacs Bras d'Or a été fermée en 2003, et la distribution des âges n'a pu être établie que d'après les résultats d'échantillonnages au filet maillant.

Au Nouveau-Brunswick, les débarquements de la pêche traditionnelle de harengs juvéniles à la fascine et à la senne de plage ont encore chuté pour se chiffrer à 9000 t , le plus bas niveau depuis 1983.

## 2004 Evaluation of 4VWX Herring

## Introduction

Atlantic herring is a pelagic species found on both sides of the North Atlantic. Herring spawn in discrete locations, to which they are presumed to home. Herring first mature and spawn at three or four years of age ( 23 to 28 cm or 9 to 11 in ), then begin a predictable annual pattern of spawning, overwintering, and summer feeding, which often involves considerable migration and mixing with members of other spawning groups. Most fishing takes place on dense summer feeding, overwintering, and spawning aggregations.

The 4VWX management unit contains a number of spawning areas, separated to various degrees in space and time. Spawning areas in close proximity with similar spawning times, and which share a larval distribution area, are considered part of the same complex. These undoubtedly have much closer affinity than spawning areas that are widely separated in space or time, and do not share a common larval distribution. Some spawning areas are large and offshore, whereas others are small and more localized, sometimes very near shore or in small embayments. The situation is complicated further as herring migrate long distances and mix outside of the spawning period both with members considered part of the same complex and with members of other spawning groups. For the purposes of evaluation and management, the 4VWX herring fisheries are divided into four components (Fig. 1):

1. SW Nova Scotia/Bay of Fundy spawning component
2. Offshore Scotian Shelf banks spawning component
3. Coastal (South Shore, Eastern Shore and Cape Breton) Nova Scotia spawning component; and
4. SW New Brunswick migrant juveniles.

Each component has several spawning areas, and there is mixing of fish among spawning components. Industry and management have explored means of managing the complexity within each component (such as distributing fishing effort among spawning areas according to their relative size) and of taking appropriate account of interaction among components (such as fishing restrictions on some areas of mixing).

Fisheries in the 4VWX area in recent years have been dominated by purse seine, weir and gillnet, with relatively minor landings by shutoff, trap and midwater trawl (Table 1,2). In Sept. 2003 a new statistics recording system called MARFIS was implemented which resulted in a few data conversion and data entry problems for herring. In particular the landings for shutoff gear have not yet been incorporated to the entry system and so are still incomplete (Table 1).

Since 1995, the herring stock assessment and related research has been enhanced by a number of projects undertaken with the assistance of the fishing industry. These include industry sampling of biological characteristics of the catch, acoustic surveys using industry vessels and tagging.

The Georges Bank spawning component (Fig. 1) is not included in this evaluation except to document Canadian herring landings from that area (Table 1). This fishery is included in the Gulf of Maine stock complex and has been recently evaluated separately (DFO 2003a).

## 1) Objectives and Management

The 2003-2006 Scotia-Fundy Herring Integrated Fisheries Management Plan (DFO 2003b) sets out principles, conditions, and management measures for the 4VWX herring fisheries. The main principle stated in the plan is "the conservation of the herring resource and the preservation of all of its spawning components".

Three conservation objectives developed and reviewed by Sinclair (1997) appear in the plan:

1) To maintain the reproductive capacity of herring in each management unit through:

- persistence of all spawning components in the management unit;
- maintenance of biomass of each spawning component above a minimum threshold;
- maintenance of a broad age composition for each spawning component; and
- maintenance of a long spawning period for each spawning component.

2) To prevent growth overfishing:

- continue to strive for fishing mortality at or below F0.1

3) To maintain ecosystem integrity/ ecological relationships ("ecosystem balance").

- maintain spatial and temporal diversity of spawning
- maintain herring biomass at moderate to high levels

An "in-season" management process, first implemented in the southwest Nova Scotia fishery during 1995, continued to be used widely within the 4 VWX management area (DFO 1997, Stephenson et al 1996,1999a). The approach encouraged surveying using the commercial fleet under scientific direction prior to fishing ("survey, assess, then fish" protocol) to ensure that effort was distributed appropriately among various components of the stock (particularly among spawning components) according to the relative size and current state of each component. The use of this approach in recent years has improved data collection
and enabled modifications to management decisions to be made with the involvement of participants and on the basis of up-to-date information.

Collaborative research efforts with the fishing industry have been important in recent years. A major portion of the herring industry (including the purse seine sector and major processors) forms the Herring Science Council (HSC), and some members of the fixed gear sector have undertaken a separate Joint Project Agreement with DFO to undertake collaborative scientific projects. The herring industry has continued to provide biological sampling and samples while the purse seine and gillnet sectors undertook key acoustic surveys. Under the auspices of the HSC a dedicated field biologist also takes part in initiatives such as tagging, summary of fleet activities (Appendix A), and analysis of acoustic records from fishing trips.

## 2) SW NOVA SCOTIA/BAY OF FUNDY SPAWNING COMPONENT

### 2.1 The Fishery

Herring fishing locations, NAFO unit areas used for catch and sample aggregation and fishing areas defined by groupings of 10 mile squares (i.e. 10 minute squares of latitude and longitude) are shown in Figures 2 to 5.

The 2003 catch limit for this component was 93,000 t, an increase of 15,000t from the previous year (Table 3, Fig. 6). Eighty percent of the catch limit was initially allocated to the mobile gear sector and $20 \%$ to the fixed gear sector, as has been done historically. Transfer of quota to the mobile fleet occurred late in the season.

Total landings from this component in 2003 (89,360t) were 12,000t higher than the previous year, and the highest since 1993 (Table 3). Increased landings by the purse seine sector $(88,000 t)$ accounted for the increase, as landings by both the gillnet sector (440t) and the Nova Scotia weirs (920t) were similar to 2002.

The temporal and spatial distribution of the purse seine fishery was generally as expected compared to the recent decade (Table 4-5). The largest purse seine fisheries occurred on the German Bank and Scots Bay spawning grounds, and on summer feeding fish off Long Island, N.S. and around Grand Manan (Fig. 7). There were substantial increases in the 2003 landings from Scots Bay and off Long Island, NS. The Lurcher area, while small overall, experienced a drop in landings of about 5,800t from 2002.

During the 1970's and 1980's, a large fishery took place on over-wintering aggregations in Chedabucto Bay. In recent years however, there has been no fishing effort in this area as traditional vessels have been successfully fishing elsewhere. In some years there has been a small fishery on over-wintering herring
in January off Halifax Harbour (Chebucto Head), but the majority of the fall and winter herring landings for the past several years have come from the New Brunswick side of the Bay of Fundy (Fig. 8-10) and take place from Oct. to Feb. The summer purse seine fishery landings (Fig. 9) took places in the same areas as in previous years. A large part of the purse seine fishery was directed on the major spawning grounds in Scots Bay and on German Bank (Fig. 11, 12) where recent catches are primarily within the pre-defined acoustic survey areas (Melvin and Power 1999). The Trinity Ledge spawning ground which is still recovering is closed to purse seine gear from Aug. 15 to Sept. 15 but there were acoustic surveys followed by some catch (354t) by gillnet gear (Fig. 13).

A small drift gillnet fishery that took place in the traditional areas (in June on the Spectacle Buoy area and in Sept. on Trinity Ledge) landed only 440t (Fig 14). Additional catches by drift gillnet gear occurred in Sept. to Oct. in the Little Hope/Port Mouton spawning grounds. There were also set gillnet catches along the Eastern Shore to the east of Halifax and near Glace Bay in Cape Breton (Fig. 15).

Catches in the Nova Scotia weirs of 921t, although only a little lower than in 2002, were the third lowest in the 40 year record of landings from this fishery (Table 3; Fig. 16). The decrease has been attributed to problems in availability of fish to this fixed stationary gear as there were substantial catches by purse seine in the Long Island area on the Bay of Fundy side of Digby Neck. The seasonal timing of the Nova Scotia weir landings has shifted in the last 4 years with a higher proportion of landings now as late as Aug. and Sept. as compared with the traditional early fishery seen in May and June previously (Table 6). Catches in recent years for the Nova Scotia weirs have been highly variable and not as consistent in their amount or timing as in the previous decade. There has also been a decline in the total number of herring weirs and the catch per weir for the Nova Scotia weir fishery (Table 7).

## Catch and Effort

In order to follow trends in the overall effort on specific fishing grounds the landings data was summarized for various areas. The number of days fished, the number of active boats fishing and the total catch was determined from the landings data. There was no available information on the number of nets fished or for soak time while fishing these nets and so Catch per Unit Effort (CPUE) was calculated as catch per day and catch per boat for this analysis.

Overall gillnet landings in the Spectacle Buoy area which take place on spawning fish in the month of June were reduced in 2004 with only 11 days fished and 69t landed (Table 8, Figure 17). However, catch per day and catch per boat were higher than recent years for the few days the fishery took place.

Gillnet landings on the Trinity Ledge spawning grounds in the months of Aug. and Sept. have shown a general decline in the number of boats fishing and days fished in the last 3 years with catches up slightly to 369 t in 2003 (Table 9, Figure 18). CPUE trends in catch per day and catch per boat also increased slightly in 2003.

Purse seine landings make up most of the overall catch and are allocated 80\% of the TAC in the SW Nova Scotia/Bay of Fundy component under the current management plan. The purse seine catch has fluctuated between 60 and 100 thousand tones since 1989 with a steady increase in recent years reflecting increases in the TAC (Table 10, Figure 19). The overall number of boats fishing and days fished has been dropping since 1990 due to some fleet rationalizations. This has resulted in increases in catch per boat and catch per day in recent years.

### 2.2 Resource Status

## Acoustic Surveys

Automated acoustic recording systems deployed on commercial fishing vessels were used to document the distribution and abundance of Atlantic herring in NAFO Division 4VWX through industry vessel surveys and fishing excursions (Melvin and Power 1999). Regularly scheduled surveys, at approximately 2-week intervals, were conducted on the main spawning components and the spawning stock biomass for each component was estimated by summing these results (Melvin et al 2004).

In 2003, four surveys were conducted in Scots Bay, three on Trinity Ledge and five on German Bank following established protocol and providing good coverage of these spawning areas consistent with previous years. Additional data from fishing nights in Scots Bay and German Bank were examined.

Biomass estimates for Scots Bay, Trinity Ledge and German Bank were approximately $133,900 \mathrm{t}$, $14,500 \mathrm{t}$, and $343,500 \mathrm{t}$ for a total surveyed SSB of 493,300 t in the traditional survey areas (Table 11). Recorded biomass on German Bank was less than the previous year, but this is thought to have been due in part to an unusually long period (22 days) between two surveys. A single fishing night survey southeast of Seal Island observed 12,200 t and there were 1,400 t of spawning fish documented in the spring near Spectacle Buoy. Based on these surveys, the total SSB for the Bay of Fundy/SW Nova Scotia component of the 4WX herring complex in 2002 spawning season was approximately 500,000t. While this represents a slight decrease, it is not considered significantly different from 2002 (Melvin et al 2004).

There continues to be evidence of reappearance of spawning on the Seal Island grounds, but this area and Trinity Ledge remained well below historical levels.

## Spawning ground turnover rates

The current acoustic survey method on spawning grounds is dependent on periodic turnover of spawning fish on the grounds. Acoustic surveys are required to be separated by at least 10 to 14 days to allow for turnover and to prevent double counting (Power et al 2002). This aspect of the assessment method was the subject of investigation in 2001 and of intensive sampling for maturity stage in the 2002 and 2003 fishing seasons. The results are summarized by Melvin et al. (2003, 2004) and were used to assist in the evaluation of turnover timing and the inclusion or exclusion of specific acoustic surveys.

## Exploitation Rates on Spawning Grounds

An important utility of the acoustic surveys is the ability to estimate partial exploitation rates for spatially and temporally different spawning groups. If a large part of the total catch is taken from spawning groups that are surveyed then the partial exploitation rates will reflect almost all of the total exploitation. This is useful information for assessing the impact of fishing on individual spawning units as well as for the overall stock component (Table 12).

For this analysis only the three major spawning components Scots Bay, German Bank, Trinity Ledge that have received consistent survey effort were included (Table 12a). Since there are questions about comparability among years only data since 1997 are shown. Catches throughout the year from the spawning grounds were assumed to be site specific, while catches from all other areas were considered non-spawning and were allocated based on the relative spawning ground SSB amounts. In addition the SSB for Seal Island and Spectacle Buoy were allocated to the German Bank spawning area (Table 12b).

The exploitation rates were calculated for the overall adjusted catch by spawning ground both as proportions (Table12c) and as instantaneous fishing mortality rates (Table 12d).

Calculation of exploitation rates by component showed that the larger grounds (German Bank and Scots Bay) have a lower overall exploitation (F) of 0.08 to 0.28 . Trinity Ledge had higher levels ( 0.18 to 1.39 ) but this may be a problem of both catch allocation and inconsistent survey effort over the period. The overall exploitation rate for the $4 W X$ stock ranged for an $F$ between 0.10 and 0.20 , which are well below to slightly below the target of $F_{0.1}=0.22$.

## Fleet Activity

A summary of daily fishery information compiled by the Herring Science Council and DFO confirmed that the fishery on this component was largely as expected in location and timing, and that there were substantial amounts of herring in some areas other than spawning grounds (Appendix 1). There has been an increase in
market for juvenile herring for both lobster bait and to offset a shortfall in weir landings which has been a traditional source of juveniles.

## Tagging

From 1998 to 2002, the Pelagics Research Council/Herring Science Council, in partnership with Fisheries and Oceans Canada, tagged herring on spawning grounds and on the major Nova Scotia overwintering grounds (Waters et al 2001). A total of 92647 herring were tagged. Although this project has concluded, tags continue to be returned with a total of 15 new returns. The information on tags returned from this study in 2003 has been summarized by Waters and Clark (2004).

## Sampling and Catch at Age

Comprehensive biological sampling continued with substantial involvement of the fishing industry. A total of 1,605 samples comprising 182,000 fish were measured for length while 8,681 fish were sampled for age. The distribution of samples by gear and month is presented in Table 13. The sources of samples are shown in Table 14 with the bulk of samples coming from the processing industry, as has been the case since 1996. Additional samples were collected by: DFO personnel, observers deployed on purse seine vessels and from DFO research surveys. Sampling from the commercial fishery was well matched to the spatial and temporal distribution of the fishery. Additional sampling from research vessel surveys during the spring and summer resulted in widespread geographic coverage as in the past (Figure 20).

Consistent with previous assessments, the catch at age was constructed using the MFD 'Catch at Age' application (version 8.03) which is a Marine Fish Division windows based program for computing catch at age statistics as part of the stock assessment process. Data files used by 'Catch at Age' were created with the 'CATCHFRM' application that was used to select fish sample data from the Pelagic Samples Database. These data included a $2 \%$ adjustment for the shrinkage due to freezing on the length measurements for frozen samples (Hunt et al 1986). The length-weight relationships, which are also required as input to the 'Catch at Age' application, were calculated using an Oracle SQL*Plus script. The catch at age statistics were then calculated from length frequency and age-length key samples. The data were grouped or combined and then age-length keys were applied to length frequencies to produce catch at age statistics by NAFO unit area, gear-type and month.

## Age Composition of the Catch

Under $\mathrm{F}_{0.1}$ fishing and constant average recruitment, the age composition of the population caught in the fishery would be expected to be similar to that shown in Figure 21. There is peak abundance at age 4, substantial fish surviving older than
age 6 and a buildup of fish at ages 11+. This expected or ideal age structure has been used in recent assessments for comparison of the actual catch at age which has been characterized by a predominance of younger ages 2-3 and few fish older than six years old (Stephenson et al 1999b, 2001; Power et al 2002, 2003).

The 2000 year-class (at age 3) dominated the catch at age by weight (about 32\% of the weight of herring landed), while the 2001 year-class (at age 2) dominated by number in the catch (46\%) (Table 15, Figure 22). The 1998 year-class, which was dominant by weight in the catch in 2002 was approximately equal in representation to the following (1999) year-class in 2003. The pattern of dominance by age 2 and 3 fish was seen across all gear components including gillnet where age 3 fish are first recruited to that gear type (Table 15, Figure 23). The catch at age was also broken down by unit area and month for the purse seine sector which makes up the majority of the overall catch (Table 16-17, Figure 24-25). Once again age 2's and 3's predominated in all areas and months, including area 4 Xr and 4 Xq on the Nova Scotia side of the Bay of Fundy.

The historical series of catch at age was extended with the current fishing year and is shown as total number caught as well as percent by age (Table 18-19). The series shows very few fish older than age 7 in recent years and has been dominated by ages 2 through 4 since 1998 (Figure 26). The series is primarily made up of fish younger than age 6 but older ages were a feature when strong year-classes (i.e. 1976 and 1983) were progressing through the fishery (Figure 27).

Age composition in the fishery deteriorated in 2003, and remains a concern. There are few old fish (few age $7+$; only $10 \%$ age $5+$ by number) and the proportion of age $4+$ in the catch has declined to about $20 \%$. The rapid decline of year-classes (including the strong 1998 year-class) implies a high total mortality.

The proportion of age 4+, 5+ and 7+ were derived from the catch at age in numbers to determine trends in the older fraction of the catch (Figure 28). Age 7+ has shown a declining trend since about 1990 corresponding to the demise of the 1983 year-class, which was the last very strong year-class in this component. Age $5+$ is more variable but has also exhibited a declining trend in recent years. Age 4+ has declined since 1996 except for 2002 with recruitment of the strong 1998 yearclass.

## Weight at Age

The average weights at age showed little change for all ages in the most recent years (Table 20 and Fig. 29), and were within the range of data observed historically (Power and Iles 2001). The most recent 5 year and 10 year average weights at age are consistently lighter than the overall series average (Figure 30) and reflect a general decline in weight at age that occurred for all ages in the mid 1980's.

### 2.3 Sources of Uncertainty

The evaluation of stock status in this area relies in large part on the spawning stock biomass estimates derived from industry acoustic surveys. There is considerable variability around individual acoustic survey estimates (standard errors are in the range of 10-60\%) although studies of individual weir catches indicate that acoustic biomass estimates are within $15 \%$ of the amount of fish harvested. Uncertainty may also arise from assumptions concerning the residence time of herring on spawning grounds, target strength estimates and the coverage of surveys in relation to the extent of spawning.

An evaluation of progress against biological objectives in the management plan (DFO 2003b) indicate that some objectives are not being met (Table 21). In particular there are limited signs of recovery for the Trinity Ledge and Seal Island spawning components and there are few fish older than age 7 in the catch indicating high total mortality and the rapid decline of year classes. Also there is apparent high total mortality and targeting on 2 year olds. Some objectives are being met, in particular on spawning components like German Bank and Scots Bay, where the SSB is at moderate levels and recent landings have been less than $20 \%$ of survey SSB.

### 2.4 Ecosystem Considerations

Herring is prominent in the diet of many fish, birds and marine mammals, and should be managed with these interactions in mind. At present, use of a natural mortality rate of 0.2 and maintenance of SSB at moderate to high levels are assumed to account for these interactions.

Recent management initiatives to protect spawning components are intended to maintain the spatial and temporal diversity of herring spawning. Increased fishing on juveniles, which are of mixed or unknown stock affinity, is inconsistent with this objective.

### 2.5 Outlook

Recent assessments of the SWNS/BOF spawning component suggested that fishing mortality should remain below F0.1 (about 20\% exploitation rate), for a number of years in order to rebuild spawning stock biomass in all spawning areas and to expand the age composition so as to meet the explicit biological objectives of management.

The 2003 fishery was 12,000t larger than in the previous year. Although acoustic surveys continue to show an SSB of approximately 500,000t, there has been a deterioration in the state of the stock and some of the conservation objectives specified for this fishery are not being met. There is an absence of older fish in the
population and increased targeting of juveniles. While there is spawning on Trinity Ledge and a small amount of spawning has been observed in recent years near Seal Island, the SSB on both Trinity Ledge and Seal Island spawning areas remain well below historical levels.

The rapid decline in year-classes (failure to reach older ages), even in the strong recent 1998 year-class, indicates high total mortality. It seems that the current catch is substantially higher than what would be consistent with a moderate F . Although these high exploitation rates have not resulted in a reduction of surveyed spawning biomass (presumably due to reasonable recruitment), the rebuilding that these recruits may have represented has been lost.

Recent catches have been consistent with the survey, assess, fish protocol of less than $20 \%$ of surveyed biomass. However the catch at age indicates that total mortality may be considerably higher. The increased trend to catch juveniles could compromise SSB, improvement in age composition and reoccupation of spawning grounds.

### 2.6 Management Considerations

The in-season management approach, which spreads the effort in the fishery spatially and temporally among spawning components, is seen as beneficial in achieving the conservation objectives. The "survey, assess, then fish" protocol is effective in spreading the catch appropriately among spawning components in proportion to their relative size and is considered an important safeguard.

Acoustic surveys have become critical to stock status evaluation. Surveys conducted in 2003 conformed to the proposed survey design. It is important that there be continued attention to coverage and survey design, in order to assure year-to-year consistency in these surveys in all spawning areas.

There has been insufficient progress towards conservation objectives in recent years (Table 21).

## 3) OFFSHORE SCOTIAN SHELF BANKS SPAWNING COMPONENT

### 3.1 The Fishery

A foreign fishery during 1963-1973 is estimated to have removed as much as $60,000 t$ per year from the offshore Scotian Shelf banks. Few herring were caught after the extension of jurisdiction in 1977 until 1996, when a fishery was initiated by the 4 WX purse seine fleet and 11,700t was taken (Table 3).

Since 1996 a fishery has taken place on feeding aggregations on the offshore banks primarily in May and June with catches ranging from 2,000 to 20,000t (Table 3). The variability in catch levels was often due to problems of fish being too deep, weather and market conditions rather than in the abundance of herring in these areas.

Landings from the 2003 fishery on the Scotian Shelf Banks (less than 1000t) were the smallest since the fishery was reactivated in 1996. Fishing by purse seine took place primarily in May and June, in the vicinity of The Patch and Western Hole (Table 1, Figure 31). In 2003, herring continued to be caught as by-catch in the domestic bottom trawl fishery on the Scotian Shelf edge and slope, but the amount was less than 70t (Table 1). There was midwater trawl activity on the offshore Scotian Shelf banks in May and November with a total of 52t landed.

The 1998 year-class (age 5) dominated the age composition of the Scotian Shelf fishery in both number and weight (Table 22, Figure 32).

### 3.2 Research and Industry Surveys

## Industry Surveys

Fleet activity/catch in the spring/early summer fishery on the offshore banks of the Scotian Shelf continued to decrease in 2003. Acoustic recorders were activated on a few occasions but insufficient quantities of fish were observed to warrant analysis. Consequently, no acoustic biomass estimates were available from the Scotian Shelf (Melvin et al 2004).

## July Bottom Trawl Survey

The summer bottom trawl survey showed few herring on the Scotian Shelf during the 1970's, increasing amounts during the 1980's and a relatively widespread distribution in recent years (Harris and Stephenson 1999, Power et al 2003, Stephenson et al 2001).

Offshore herring catches from this survey in 2003 were the second highest in the 34-year time series, with an average of over 170 fish per standard tow for strata 55 through 78 (Table 23, Figure 33). Survey catches of the past six years have been the highest on record (and in the 20 years in which the same vessel and gear have been used).

Trends are similar for the combined strata from each of the areas 4W and 4X (Table 23, Figure 34). The strata areas used for selection of trawling stations in this ground-trawl survey series are shown in Figure 35. Herring were again widely distributed on banks west of Sable Island (Figure 36) and were comparable to average catches from the last ten years (Figure 37). The overall size distribution for catches from all strata in 4 WX shows that the bottom trawl is capable of catching a complete spectrum of herring from 5 cm up to 40 cm (Figure 38). There
are few fish larger than 35 cm in recent years and there appears to be a modal progression for the past three years showing the possible tracking of a recent year class.

The survey data for areas $4 W X$ combined were also analysed by age to produce stratified mean numbers per tow over the series (Table 24, Figure 39). There was a lack of consistency with the large year-classes observed in the fishery and a lack of tracking of these year-classes from year to year. There have been two major changes in the catch rates by bottom trawl over the series; the first is with to the introduction of the Alfred Needler in 1987 and a second large increase since 1994. The plot by age and year shows a lack of older ages in the catch over the past decade but does not appear to track strong year classes consistently (Figure 40).

## Spring 4VsW Herring Survey

Since 1986 there has been a spring ground trawl research survey which had a primary goal of investigating NAFO area 4 VsW cod. This survey has followed standard groundfish survey protocols using the same vessel (Alfred Needler), gear (Western Ila bottom trawl) and strata (Table 25, Figure 41). The herring catches from this survey have been highly variable from year to year with no consistent area patterns (Figure 42-43) or time trends (Figure 44). The recent increase since 1999 which was seen in the July trawl survey series is not evident in the spring 4 VsW survey data. The overall length distribution for all strata combined shows a broad size range of herring captured including substantial numbers larger than 35 cm in 2003 (Figure 45).

## Fall Herring Research Survey

There was no fall herring research survey on the Scotian Shelf due to a fire on the research vessel CCGS Alfred Needler.

### 3.3 Outlook and Management Considerations

The summer bottom trawl research survey demonstrates that there is a considerable abundance of herring widely spread over the offshore banks of the Scotian Shelf. Information from previous assessments indicated the presence of at least some autumn spawning on Western Bank in recent years. There is very little new information to add and no reason to change the previous outlook:

- Recorded landings in the foreign fisheries of 13,000t to 60,000t between 1969 and 1973 did not appear to be sustainable.
- The initial catch allocation for 2004 should not exceed the 12,000t reference value used in the recent fishing plans.

There continues to be insufficient documentation of stock size, distribution and spawning behaviour for this component. Industry, DFO Science and Management are encouraged to continue to work together to improve the biological basis for management. There continues to be the need for industry surveys to estimate abundance.

## 4) COASTAL (SOUTH SHORE, EASTERN SHORE AND CAPE BRETON) NOVA SCOTIA SPAWNING COMPONENT

### 4.1 The Fishery and Resource Status

In addition to traditional coastal fixed gear fisheries for subsistence and personal bait, there has been an increase in the number of active gillnet licenses in recent years aimed at spawning herring for the roe market (Clark et al 1999). This was the eighth year for a fishery on spawning fish off Halifax/Eastern Shore and the seventh year of gillnet roe fisheries off Little Hope/Port Mouton and Glace Bay.

Recorded landings (9,000t) in 2003 in the four major gillnet fisheries along the coast of Nova Scotia were higher for Little Hope/Port Mouton but lower in Eastern Shore/Halifax and Glace Bay (Bras d'Or Lakes remained closed) (Table 26).

Biomass estimates from surveys of the major coastal Nova Scotia spawning components were higher in 2003 with large increases in estimated SSB for the Little Hope, Eastern Shore and Glace Bay areas (Table 27) (Melvin et al 2004). There was no acoustic survey effort in the Bras d'Or lakes during 2003. Management of these spawning components using "survey, assess, then fish (<10\%)" protocol is considered useful when the components are considered to be healthy and of sufficient size. The history of the application of this protocol has had some mixed success due to some occasional problems in executing surveys (Table 28).

## History of Recent Catch and Effort

The history of the recent catch and effort by gillnet on the three main spawning components along coast Nova Scotia is documented in Table 29-31. Rather than showing the number of licenses, many of which are inactive, the landings data was used to report days fished, number of active boats, catch per day and catch per boat. The number of nets fished or soak time was not readily available but these have not changed substantially by spawning ground over the recent period.

## Little Hope

The fishery occurred in the Port Mouton/Little Hope area in September and October with a total of 4,500t of herring landed (Figure 46). Daily length samples
were taken from October 1-9 with most fish larger than 25cm (Figure 47). Only one sample of spawning fish was available from Oct. 1 with $93 \%$ in spawning condition (Figure 48). Sampling indicated that the catch was composed primarily of 19961998 year-classes (ages 5-7) (Table 32, Figure 49). Both catch and effort as measured by the number of active boats have been increasing in this area since 1997 (Figure 50, Table 29). The CPUE as measured by catch/boat for the spawning season has been relatively stable since the year 2000.

A total of four surveys took place on the spawning ground of which only the final one had a boat with a sounder recording system. An acoustic estimate of $62,500 \mathrm{t}$ ( $56 \%$ SE) SSB based on one mapping and one acoustic survey was the highest for this area to date (Table 27) (Melvin et al 2004).

## East of Halifax (4W Eastern Shore)

The roe fishery for the Eastern Shore area in September and October landed 2,700 (Figure 51). Sampling was limited to the two survey nights and indicated that the catch was composed of spawning fish mainly of the 1996-1998 yearclasses (age 5-7) (Figure 52-54, Table 32). Total catch and effort have increased in the most recent two years over the earlier period since 1996 (Table 30, Figure 55). The CPUE measures, however, for catch/slip and catch per boat have remained relatively stable.

Acoustic surveys undertaken by the Eastern Shore Fishermen's Protective Association in September and October 2003 estimated an SSB of 76,500t (19\% SE), the highest for the area to date (Table 27) (Melvin et al 2004).

## Glace Bay

The fishery off Glace Bay, Cape Breton took place in September and October with total landings of 1,900 t, which was a large decrease from the previous year (Table 26, Figure 56). The reduction in catch was attributed to timing problems associated with closing and opening of the fishery as well as weather affecting behaviour of the herring schools. Length samples indicated large herring, mostly over 30 cm in total length (Figure 57), while maturity samples taken in September were primarily of spawning fish (Figure 58). Fish aged 7 (1996 year-class) dominated the catch (Figure 59, Table 32).

Approximately 31,500 t of spawning herring was estimated from three mapping surveys off Glace Bay in the month of September.

Total catch and effort as measured by the number of boats and days fished has been higher in recent years for this area (Table 31, Figure 60). There was a decrease in CPUE in 2003 due to timing of the fishery opening and weather related effects on fish behavior.

In the July groundfish survey, stratum 42 (Figure 35) covers the area of 4 Vn that includes the fall roe fishery off Glace Bay. In 2001, survey catches by number and weight from this stratum were the highest in the past twelve years (Table 33). In 2002 and 2003, however, overall catches of herring in this stratum were reduced dramatically. There is a great deal of annual variability in the numbers and weights of herring caught by this survey and it does not appear to be representative of herring abundance as seen in the fall spawning areas.

## Bras d'Or Lakes

The fishery was closed. The Eskasoni Fish \& Wildlife Commission Inc. continued to gather scientific samples of the Bras d'Or Lakes herring in the absence of a commercial fishery again in 2003 (Figure 61-63). In addition, herring spawning locations were recorded and spawning beds measured. The samples showed a broad age distribution, dominated by age 7 (1996 year-class) (Figure 64).

Sampling and spawning in 2003 occurred later in the year compared to previous years due to the presence of ice on the Bras d'Or Lakes that had covered approximately $80 \%$ or more of the Bras d'Or Lake. Herring samples were obtained using multi-mesh sized nylon nets each 150 ft in length constructed of differing sizes of mesh ( $15 / 16,1 \frac{1}{2}, 13 / 4,21 / 2$, and $23 / 4$ ) to capture herring. A metal egg grabber was also used on spawning beds to first determine egg presence. When eggs were discovered, scuba or snorkeling was used to measure the spawning bed. Great care was taken to prevent damage or reduce egg presence on spawning beds.

The spring spawning herring component were sampled weekly between April $24^{\text {th }}$ and June 3, 2003 in East Bay, Big Harbour Island, Soldier's Cove, Iona, Grand Narrows, West Bay and Baddeck Bay. Confirmation of spring spawning occurred at Black Rock, Baddeck Bay (3 sites), Lighthouse Point, MacKinnon's Habour and Marble Mountain. No evidence of spawning could be found between Johnstown to St. Peter's, West Bay or around the Barra Strait (either direction). The River Denys Basin was not checked.

Sampling continued weekly after the spring run to determine if herring were still present in the Bras d'Or Lakes. Herring in spawning condition (maturity 5 and 6) were found in East Bay on Sept. 17 and herring were still captured in small quantities in the Bras d'Or Lakes until Nov. 28, 2003 after which sampling ceased due to weather. However, evidence of fall spawning was not found and it is suspected that spawning occurred at depths greater than 30 ft . Visibility tends to be poor under water at this time in the Bras d'Or Lakes and the egg grab contraption was difficult to drag at deeper depths.

In 2003 no acoustic surveys were conducted in the Bras d'Or lakes to document the abundance of spawning herring.

### 4.2 Outlook and Management Considerations

There is no overall quota for the coastal Nova Scotia spawning component and apart from the areas mentioned above; the size and historical performance of various spawning groups are poorly documented. In addition to traditional fisheries for bait and personal use, there are new directed roe fisheries on the spawning grounds.

As the inshore roe fisheries off Glace Bay, East of Halifax and Little Hope have developed, participants have contributed to sampling and surveying and the fisheries have attempted to follow the 'survey, assess, fish' protocol. Surveys and sampling in these areas improved over previous years and should be continued.

Management approaches and recent research efforts have improved knowledge in these three areas, but there has been no increase in knowledge in adjacent areas. Individual spawning groups within this component are considered vulnerable to fishing because of their relatively small size and proximity to shore. As in the past five years, it is recommended that no coastal spawning areas should experience a large effort increase until much more information is available on the state of that spawning group, and there should be no new fisheries developed when there is uncertainty regarding stock composition and degree of mixing.

It has been noted since 1997 that the status of herring in the Bras d'Or Lakes is cause for concern. Spawning is still absent from some traditional areas and the observed biomass of spring spawners is very low. It is therefore appropriate to reiterate that from a biological perspective, that no fishing take place on this spawning component.

## 5) SW NEW BRUNSWICK MIGRANT JUVENILES

The southwest New Brunswick weir and shutoff fisheries have relied, for over a century, on the aggregation of large numbers of juvenile herring (ages 1-3) near shore at the mouth of the Bay of Fundy. These fish have been considered to be a mixture of juveniles, dominated by those originating from NAFO Subarea 5 spawning components, and have therefore been excluded from the 4WX quota.

Mature herring (ages 4+) taken in this fishery are considered to be of 4 WX origin. The 2003 catch was dominated by the 2001 year-class (age 2), which made over $80 \%$ of the catch by number and $70 \%$ of the catch by weight (Table 34, Figure 6566).

The recent US management plans (NEFSC 1998, 2004) assumes that all of the juvenile herring from this fishery originate from the US "coastal complex" ( $5 \mathrm{Y}+5 Z$ ) which is reported to be at record high levels of abundance.

The number and distribution of active weirs have decreased over the past decade, due in part to the conversion of sites to aquaculture, as well as the reduction in landings over the past decade in the Passamaquoddy Bay area (Table 3, 7). There was a further drop in landings in the traditional New Brunswick weir and shutoff fishery to 9,000 - the lowest since 1983 - and there is concern for this fishery (Table 1-2, Figure 67).

In 2002 the Fundy Weir Fishermen Association, Inc., in partnership with the New Brunswick Department of Agriculture, Fisheries and Aquaculture, the Grand Manan Fishermen's Association, Connors Brothers Ltd. and Fisheries and Oceans, Canada, initiated a tagging program, to be conducted over a three year period. The purpose of this project is to investigate the seasonal movements and migration of herring in the Bay of Fundy with the long-term goal of providing information on stock structure. Since the start of this project a total of 46,330 herring have been tagged and 1,379 tags have been recovered. The results to date are summarized by Waters and Clark (2004).

## 6) $\mathbf{5 Z}$ Georges Bank

The activities of a single midwater trawler on the Canadian portion of Georges Bank (area 5Z) have also been summarized (Table 1). There were a total of 1,750t landed from July to Oct. with most of the landings in September (Figure 68). These catches were dominated by the 1998 year-class at age 5 in numbers and weight (Table 35, Figure 69).

## Acknowledgements

The authors would like to thank the following for their invaluable contributions to the provision of survey data and other assistance in the preparation of this report: Shelley Denny; Atlantic Herring Co-Op; Cape Breeze Seafoods; Comeau's Sea Foods Ltd.; Connors Bros. Ltd.; Eskasoni Fish \& Wildlife Commission Inc.; Herring Science Council; Eastern Shore Fishermen's Protective Association; Glace Bay herring gillnet group; Little Hope Management Committee; Scotia Garden Seafood Inc. and South-West Seiners.

| Annual landings by purse seiners are defined for the period from October 15 of the preceding year to October 14 of the current year. *Adjusted totals includes misreporting adjustments for 1978-84 (Mace 1985) and for 1985-93 (Stephenson 1993, Stephenson et al 1994) All landings by other gear types are for the calendar year. |  |  |  |  |  |  |  |  |  |  |  |

Table 21. An evaluation of 2003 fishery observations for the SW Nova Scotia spawning component progress against biological objectives in the management plan for the fishery. (DFO 2003b).

|  | Objective | Met | Not Met |
| :---: | :---: | :---: | :---: |
| 1 | Maintain reproductive capacity |  |  |
| 1a | Persistence of all spawning components | German Bank and Scots Bay OK; Trinity recovering | Limited signs of Seal Island component Increased fishing on juveniles of mixed origin inconsistent with this objective |
| 1b | Maintain biomass of each component | German Bank and Scots Bay | Trinity Ledge and Seal Island |
| 1c | Maintain broad age composition |  | Not met in all areas Few fish older than age 7 ; only $20 \% 4+$. Rapid decline of year-classes (including strong 1998 year-class) |
| 1d | Maintain long spawning period | German Bank and Scots Bay | Trinity and Seal Island |
| 2 | Prevent growth overfishing |  |  |
| 2a | Fishing mortality at or below F0.1 | Landings in recent years less than 20\% of surveyed SSB | High total mortality and targeting of 2 year olds |
| 3 | Maintain ecosystem integrity / ecological relationships |  |  |
| 3 a | Maintain spatial and temporal diversity of spawning | German Bank and Scots Bay | Insufficient spawning at Seal Island and Trinity Ledge |
| 3b | Maintain biomass at moderate to high levels | Acoustic surveys indicate moderate SSB |  |

# 2003 4WX Herring Fishery: Report of Fleet Activity 

L.M. Annis<br>Herring Science Council<br>P.O. Box 517, Yarmouth, NS, B5A 4B4

The herring industry in association with the Herring Science Council provides an annual summary of seiner fleet activity throughout the fishing season. This gives a general overview of the activities of the purse seine fleet and highlights important anecdotal information that may otherwise be lost. Information was gathered through association records, captain's reports and comments, through HSC and DFO staff, and through DFO landings and samples databases. The following is a summary of the activities for the 2002-2003 quota year purse seine fisheries. Please refer to Tables 1-5, and Figures 1-6 to see a graphic organization of the landings per week and length of fish per week.

## Offshorel Scotian Shelf Banks

## Summary

- Reactivated fishing area since 1996
- The 2003 Offshore/Scotian Shelf purse seine fishery took place on Weeks 20, 24, and 25.
- Overall, little fish was caught in the Offshore Banks.
- Weather was described as poor for the majority of the 2003 Offshore/Scotian Shelf fishery.
- Fish were scarce and staying deep in the water and were not aggregating well in most evenings. The fish landed were described as being in very good condition with excellent fat content.
- Other non-seining boats reported herring at the edge of the Scotian Shelf.

## Week 20: May 11- May 17

This week three landings were made from Western Hole, with a total of 55 t landed.

## Week 24: June 8- June 14

Eight boats moved around to Halifax this week. Landings were made in Sheet Harbour and Halifax from the Patch. Bad weather prevailed this week. Fish were staying deep in the water column, at 10-11" in length, and were for the food market. 13 landings were made from the Offshore Banks with a total of 722 t landed.

## Week 25: June 15- June 21

Several boats searched for fish in around the "Bull Pen" at the start of the week. Fish were staying very deep and tight to bottom. The fish could be picked up on sounders, but were unable to be caught. One Captain said that you had to be on top of them when they came up in the water column to catch them. Only a few of
the boats made successful sets. The fleet moved out of this area at the end of the week and headed back to SW Nova Scotia.

## South West Nova Scotia Component

The quota year for South West Nova is from the period October 15 to the following October 14, and so catches from October 15 to December 31, 2002 are included in the quota total. The 2003 -year fishing weeks are summarized separately below.

## Summary

- The purse seine fleet concentrated their efforts on pre-spawning aggregations mainly on the Long Island Shore, the Grand Manan Banks, Gannett Dry Ledge, and Lurcher.
- Spawning aggregations were targeted on German Bank and Scots Bay.
- Weeks 1-8 showed activity in NB Coastal and the Grand Manan Banks. This was different from 2002, where activity was shown in weeks 2-5.
- Fishing started later in the spring, at Week 18: April 27- May 3, compared to 2002 when the fishery started at Week 16: April 13-19.
- The weather varied across the season with some very suitable fishing weather early in the season, to unsuitable weather late in the season.
- In May about $89 \%$ of landings came from the Long Island Shore, June the majority was from Grand Manan Banks at $35 \%$, July the greatest was $38 \%$ from Scots Bay. In both August 57\% of the landings came from Scots Bay, September the majority was from German Bank at $65 \%$. The month of October had $48 \%$ of landings coming from the Grand Manan Banks.

## 2002 Fishing Weeks

## Week 42: October 15- October 19

426 tons (6 landings) of herring was landed in NB Coastal, and 1339 tons (26 landings) in Grand Manan.

## Week 43: October 20- October 26

529 tons (16 landings) was landed on the Grand Manan Banks, 986 tons (12 landings) in NB Coastal, and 110 tons ( 1 landing) on the Long Island Shore.

## Week 44: October 27- November 2

445 t were landed in Grand Manan from 10 landings, and 559 in NB Coastal from 15 landings.

## Week 45: November 3- November 9

382 t was landed on the Grand Manan Banks from 9 landings, and 73 t were landed in NB Coastal from 1 landing.

Week 46: November 10- November 16

533t was landed on the Grand Manan banks from 6 landings, and 78t on the Long Island Shore from 1 landing.

## Week 47: November 17- November 23

$482 t$ was landed on the Grand Manan banks this week from 6 landings.

## Week 48: November 24- November 30

$406 t$ was landed on the Grand Manan banks this week from 6 landings.

## Week 49: December 1- December 7

111t was landed on the Grand Manan banks this week from 2 landings, and 18t on the Long Island Shore from 1 landing.

## 2003 Fishing Weeks

## Week 1: January 1- January 4

655 t of herring was landed in NB Coastal from 16 landings to start out the year 2003.

## Week 2: January 5- January 11

301t was landed in NB Coastal from 14 landings, 235t (10 landings) in Grand Manan.

## Week 3: January 12- January 18

293t was landed in NB Coastal from 13 separate landings.

## Week 4: January 19- January 25

$270 t$ (13 landings) was landed in NB Coastal and 39t (2 landings) in Grand Manan.

## Week 5: January 26- February 1

$78 t$ (6 landings) were landed in NB Coastal, and 99t (5 landings) in Grand Manan.

## Week 6: February 2 - February 8

158t (9 landings) was landed on the Grand Manan Banks, and 88 t (5 landings) was landed in NB Coastal.

## Week 7: February 9 - February 15

130t from 5 landings was landed in NB Coastal.

## Week 8: February 16- February 22

12t were landed from one landing in Grand Manan Banks, and 25t from 2 landings in NB Coastal.

## Week 18: April 27- May 3

35 tons was landed on the Gannet Dry Ledge this week from 4 landings. 71 tons of herring was caught on German Bank this week fro a total of 7 landings.

## Week 19: May 4- May 10

494 t was caught on the Long Island Shore this week, from a total of 11 landings. 300 t was captured from Lurcher this week from 11 landings. 52 t from Gannet Dry Ledge from 2 landings. 16 t was gathered from German Bank from a total of two landings.

## Week 20: May 11- May 17

$103 t$ (5 landings) was caught on Grand Manan, and 1510 t (41 landings) from Long Island Shore.

## Week 21: May 18- May 24

14 t (2 landings) of herring was landed in Grand Manan this week, and 1152 t (36 landings) of herring was landed on the Long Island Shore.

## Week 22: May 25- May 31

Several seiners fished the Long Island Shore this week. Herring was in good amounts and were bunching up well in the water. 590 t of herring was landed this week from the Long Island Shore, from a total of 23 landings.

## Week 23: June 1- June 7

7 gillnet boats fished on Green Island/Spectacle Buoy area this week. A good amount of spawning fish was observed and recorded. 473t (17 landings) of herring was landed from the seiners this week in Grand Manan. An additional 82t (3 landings) was landed on the Long Island Shore.

## Week 24: June 8- June 14

347 t (13 landings) of herring was landed in Grand Manan, and $82 t$ (3 landings) was landed on the Long Island Shore.

## Week 25: June 15- June 21

$480 t$ (19 landings) of herring was landed in Grand Manan, 149t (7 landings) was landed on the Long Island Shore, 6t (1 landing) from the Gannett Dry Ledge, and 80t (1 landing) from German Bank. Some seiners moved around to Halifax this week. An inshore gillnet survey of Spectacle Buoy/ Green Island area was carried out on Sunday June 8, 2003. 10 gill-netters participated in the survey. Very little fish was found in comparison with the sightings from the previous week.

## Week 26: June 22- June 28

The seining fleet moved from the Offshore Banks back to Southwest Nova Scotia this week. Very little herring was observed this week. Sets made in the area produced "junk". The water temperature was fairly warm between 54.3 and $55^{\circ} \mathrm{F}$. Despite the lack of herring, 161t (6 landings) was landed on Grand Manan, 620t
(20 landings) was landed on the Long Island Shore, 1096t (16 landings) was landed in the Seal Island Area, and 223t (5 landings) was landed from German Bank.

## Week 27: June 29- July 5

Good amounts of herring were landed this week for the food market. Approximately 10 boats were active south of the Seal Island area. The water temperature ranged from $50-54^{\circ} \mathrm{F}$, and the weather was described as good. Fish size ranged between 10-13 inches. These fish are thought to be of the 1998-year class, and were caught full fat and full of feed. The Teardrop, 28 miles southwest of Yarmouth, was also fished, and again large fish full of feed were encountered.1148t ( 35 landings) was landed from Grand Manan, 22 t ( 1 landing) from the Long Island Shore, 34 t (1 landing) from Lurcher, 3651t (47 landings) from Gannet Dry Ledge, and 795t (12 landings) from German Bank.

## Week 28: July 6- July 12

Seiners fished the Teardrop and an area North of German Bank this week. Good amounts were landed. Fish size was good ( $9-11$ inches), with an excellent size range depicting various year classes. Fat content of the fish was very good, anywhere from $13-15 \%$. Fish caught were excellent size for fillets. Fish were staying deep in the water column, and only coming up after dark. 722t (33 landings) was landed from Grand Manan, 212t (5 landings) was landed from Long Island Shore, 1240t (17 landings) was landed from Lurcher, 1725t (20 landings) was landed from Gannet Dry Ledge, and 99t (2 landings) was landed from German Bank.

## Week 29: July 13- July 19

A good amount of fish was noted on the evening of July 14 on the Long Island Shore. This was not roe fish, but a good sign of what may be to come. Whales were observed off White Head this week. Fish on German Bank were appearing suddenly, when darkness fell, there would be lots of fish showing in the area. Some felt that the transition from no fish showing on the sounders to plenty of fish was stronger this year. This week several seiners moved operations to Scot's Bay. Landings were made over a variety of areas, including 139 t ( 4 landings) on Grand Manan, 1177t (48 landings) on the Long Island Shore, 128t (2 landings) on Lurcher, 391t ( 7 landings) on Gannet Dry Ledge, 687t (12 landings) on German Bank, and 1187 t (12 landings) in Scot's Bay.

## Week 30: July 20- July 26

Fishing activity was mainly concentrated on the Long Island Shore and Scot's Bay this week. It was reported that in Scot's Bay this week fish were not yet in quantities to warrant the first survey of the season in that area. The fish were in small bunches and were in hard condition. Fish were generally seen off of Margaretsville. 1057t (37 landings) of herring was landed on the Long Island Shore, 18t (1 landing) on German Bank, and 1919t (33 landings) in Scot's Bay.

## Week 31: July 27- August 2

This week several seiners concentrated on Scot's Bay. The first survey of Scot's Bay was conducted on the evening of July 31. Many of the Captain's felt that the $31^{\text {st }}$ was not a good night to survey, and many felt that the fish were showing up later this year than in previous years. This survey was attended by a representative from DFO Science. This week 5562t (56 landings) were landed in Scot's Bay, 149t (2 landings) in German Bank, 289t (10landings) in Grand Manan, and 353t (17 landings) in Long Island.

## Week 32: August 3- August 9

Scot's Bay was active again this week, with the majority of the weekly landings coming from that area (4189t from 53 slips). Late into the week, it was being discussed if there should be a survey this week. By Friday it was decided that the second survey of Scot's Bay should be on the following Sunday. Fish this week was landed in three other areas: 495t (12 landings) in Grand Manan, 405t (13 landings) on Long Island and 387t (4 landings) on German Bank.

## Week 33: August 10- August 16

Week 33 started out with a Sunday night survey, August $10^{\text {th }}$ in Scot's Bay. There was great participation in the survey, and a good amount of fish was documented that night. This survey was directed by a representative of the Herring Science Council. The week went on with high landings in Scot's Bay, 3763t from 46 slips. Other areas showed 361t (16 landings) from Grand Manan, 90t (3 landings) from Long Island Shore, 172t (5 landings) from Gannet Dry Ledge, and 99t (2 landings) from German Bank.

## Week 34: August 17- August 23

Landings this week decreased in Scots Bay to 1601t (26 landings), however they increased slightly in Grand Manan (751t), and German Bank (599t). Again, toward the end of the week discussions were held to decide if there should be another survey. A survey was then planned for the night of Sunday August 24 in Scots Bay.

## Week 35: August 24- August 30

The third survey of Scots Bay was completed this week on the evening of August 24. Representatives from DFO Science and the Herring Science Council participated in this survey. Landings in Scot's Bay dramatically dropped this week to 636t with most boats moving out of the area. Six boats fished German Bank this week. Fish were staying deep and were reported to be in the 10-11 inch range. These fish were also in roe and food condition. The weather was good overall for the week. The first survey of German Bank was completed on August 29. This was a non-fishing survey and was run by the fisherman and the industry associations. Landings in German Bank increased greatly, with a grand total of $3813 t$ from 43 landings. Landings were also made from Grand Manan (349t), Long Island Shore (31t), Lurcher (59t), and Gannet Dry Ledge (55t).

## Week 36: August 31- September 6

This week the weather was good, except one day (September 5) that was bad. Between eight and ten vessels fished German Bank this week. The fish were reported as being in the range of $10-11$ inches, and were in roe condition. The water temperature was $52-53^{\circ} \mathrm{F}$. Fish were staying tight to bottom and were showing up good on the sounders. The total landings from German Bank were 3737 t . On the evening of September $6^{\text {th }}$, several seiners moved back into the Scots Bay area to survey. Not a great amount of fish was documented, and only $339 t$ were landed that week from 3 landings. Landings also came from Grand Manan (551t), Gannet Dry Ledge (187t), and Long Island Shore (125t).

## Week 37: September 7- September 13

The weather was good all week. 10 herring seiners fished German Bank this week. The fish were staying deep in the water column and were in roe condition. The second German Bank survey of the season was conducted on September $8^{\text {th }}$. This was a non-fishing night, with good amounts of fish noted on the Spawn Tow. The water temperature was $53^{\circ} \mathrm{C}$ all week and the fish on the Spawn Tow were at a depth of 33 fathoms. Over the duration of the week, most of the boats were able to get their fish in one set. The fish were described as being more plentiful than last year, and the fish were staying closer to the bottom. Landings in German Bank totaled 5406t (64 landings). 229t was also landed in Grand Manan, 406 on the Long Island Shore, and 178 on Gannet Dry Ledge.

## Week 38: September 14- September 20

10 boats fished German Bank this week and landed a total of 3281t of herring. The fish were in roe and food condition. All boats seemed to get the fish they needed over the week's activities. Fish were showing up well on the Spawn Tow, at depths of 33 fathoms and with a water temperature of $53^{\circ} \mathrm{C}$. The night of September $18^{\text {th }}$ was the third German Bank survey. This was once again a nonfishing night. The Captains felt the survey went very well, with eight boats participating. Other areas fished were Grand Manan (1029t), Long Island Shore (239t), and Gannet Dry Ledge (178t).

## Week 39: September 21- September 27

The weather was good this week. Between eight and nine seiners fished German Bank (307t) this week. The fish caught were in roe condition. The fish at the start of the week were showing on the sounders as a skimmer on bottom, but most vessels were able to get the fish they needed. On the nights of the $23^{\text {rd }}$ and $24^{\text {th }}$, there was a great amount of fish noted to the east of the Spawn Tow. Toward the end of the week, many boats moved on for bait and were fishing on the Grand Manan Banks (2896t landed).

## Week 40: September 28- October 4

The weather this week was not great for fishing. Hurricane Juan moved through the Halifax area on the evening of September 28. The remainder of the week showed windy conditions. German Bank was almost inactive this week. Most of
the seiners were fishing for the bait market, and were concentrating on the Grand Manan Banks, landing a total of 3327t of herring. 220t was also landed on the Long Island Shore, and 59t was landed on German Bank. It would have been ideal to have a survey on this week, but it was not able to happen.

## Week 41: October 5- October 11

9-10 vessels fished German Bank this week (1594t). Weather conditions started out poor this week, but improved toward the end of the week. On the night of October 6, there were not many fish to be found on German Bank. By the night of the $7^{\text {th }}$, the situation had greatly improved, with good amounts of herring in the area. The fish were staying deep in the water and were in roe condition. Recordings were not especially good, due to weather conditions. On October 10, ten vessels participated in the $4^{\text {th }}$ survey of German Bank. Some fish was noted on bottom, but there was not the quantity that had been there earlier in the week. The fish were very deep after midnight on the survey night, so they could not be caught. Some of the Captain's felt that they had missed the fish that was there in the middle of the week, and that the fish had spawned and then moved out of the area. Long Island Shore (2140t) and the Grand Manan Banks (1610t) were also very active this week with high landings in both places.

## Week 42: October 12- October 14

The 2002-2003 fishing season ended on the $15^{\text {th }}$ of October. Landings this week were not as high as previous weeks. Grand Manan (331t), Long Island Shore (221t), German Bank (153t), and NB Coastal (670t) were the four areas fished this week. The industry wanted to get in one more survey for this quota year, but had to wait until the $20^{\text {th }}$ of October for the $5^{\text {th }}$ survey of German Bank.

## Acknowledgements:

A sincere thank you is extended to all captains who provided me with information throughout the fishing season. Thanks to Donna Larkin of South West Seiners Co. Ltd., and Joy Fry of the Atlantic Herring Co-op for all of their help in producing this document. A special note of thanks to Captain Glenn d'Eon for providing me with fishing activity reports throughout the fishing season.

## Appendix A: Report of Fleet Activity

Table 5. Herring mean size ( mm ) and number of samples collected from length frequency purse seine catch sampling by fishing grounds for weeks 29 to 48 in calendar year 2003.

Figure 1. Herring purse seine catches ( t ) and total number of slips (landings) by week from Oct. 15, 2002 to Dec. 31, 2002 for the 2002-2003 quota year (data from the MARFIS commercial landings system).

Figure 2. Herring purse seine catches (t) and total number of slips (landings) for weeks 1 to 21 in the 2002-2003 quota year (data from the MARFIS commercial landings system).

Figure 3. Herring purse seine catches (t) and total number of slips (landings) for weeks 22 to 33 in the 2002-2003 quota year (data from the MARFIS commercial landings system).

Figure 4. Herring purse seine catches (t) and total number of slips (landings) for weeks 34 to 41 in the 2002-2003 quota year (data from the MARFIS commercial landings system).

Figure 5. Herring purse seine catches ( t ) and total number of slips (landings) by week from Oct. 15, 2003 to Dec. 31, 2003 for the 2003-2004 quota year (data from the MARFIS commercial landings system).

Figure 6. Herring purse seine catches ( t ) and total number of slips (landings) by week from Jan. 1, 2004 to Feb. 4, 2004 for the 2003-2004 quota year (data from the MARFIS commercial landings system).

[^0]:    * This series documents the scientific basis for the * La présente série documente les bases evaluation of fisheries resources in Canada. As such, it addresses the issues of the day in the time frames required and the documents it contains are not intended as definitive statements on the subjects addressed but rather as progress reports on ongoing investigations.

    #### Abstract

    scientifiques des évaluations des ressources halieutiques du Canada. Elle traite des problèmes courants selon les échéanciers dictés. Les documents qu'elle contient ne doivent pas être considérés comme des énoncés définitifs sur les sujets traités, mais plutôt comme des rapports d'étape sur les études en cours.

    Research documents are produced in the official language in which they are provided to the Secretariat.
