Abstract

The commercial Atlantic salmon fishery moratorium, implemented in insular Newfoundland in 1992, entered its 12th year in 2003. Returns of small and large salmon in 2003 improved over 2002 (a below average year) for most rivers. However, in relation to the moratorium means, many rivers declined or remained similar. Increased recruitment of small salmon for most rivers on the northeast, east, and northwest coasts, corresponding to greatly increased spawning escapements in 1992-1996 as a result of the closure of the commercial fishery, have not materialized. The proportion of large salmon in total returns in 2003 decreased from 2002 and the moratorium means in most cases. Conservation egg requirements were met or exceeded in only ten out of 24 rivers or sections of rivers in 2003. Virtually all rivers in insular Newfoundland were closed to angling for varying periods (mainly in August) in 2003, due to low water levels and high water temperatures. Recreational fishery catches of small and large salmon, effort expenditure, and catch rate for insular Newfoundland overall in 2003 were below average. Sea survival increased over 2002 for Campbellton River, Rocky River, and Western Arm Brook while decreases were noted for Northeast Brook, Trepassey and Conne River. In the case of Conne River, survival in 2003 was the lowest on record. Smolt production in 2003 decreased from 2002 in four out of five rivers, the exception being Campbellton River. When smolt production decreases, returns of small salmon are expected to be lower in the following year, unless correspondingly there are increases in marine survival that offset decreased numbers of smolts. The converse holds when there are increases in smolt production.

Résumé

Entré en vigueur à l'île de Terre-Neuve en 1992, le moratoire sur la pêche commerciale du saumon atlantique, commençait sa douzième année en 2003. Dans la plupart des rivières, les remontes de petits et de gros saumons ont été meilleures en 2003 qu'en 2002 (année de remontes inférieures à la moyenne). Toutefois, les remontes dans de nombreuses rivières ont baissé ou sont restées stables par rapport aux moyennes sur la durée du moratoire. Dans la plupart des rivières sur les côtes est, nord-est et nord-ouest, il n'y a pas eu d'augmentation du recrutement de petits saumons correspondant aux échappées grandement accrues de 1992 à 1996 à la suite de la fermeture de la pêche commerciale. Dans la plupart des cas, la proportion de gros saumons dans les remontes totales a diminué en 2003 par rapport à 2002 et à la moyenne sur la durée du moratoire. En 2003, la ponte a été suffisante pour satisfaire les besoins de conservation dans seulement dix des 24 rivières ou tronçons de rivières. En 2003, la pêche à la ligne a été fermée dans pratiquement toutes les rivières de l'île de Terre-Neuve durant diverses périodes (surtout en août), en raison de niveaux d'eau bas et de températures de l'eau élevées. En 2003, les captures, l'effort et le taux de capture de la pêche récréative du saumon dans l'ensemble de l'île de Terre-Neuve ont été inférieurs à la moyenne. Par rapport à 2002, la survie en mer a augmenté chez les saumons des rivières Campbellton et Rocky et du ruisseau Western Arm, tandis qu'elle a diminué chez ceux des rivières Trepassey et Conne et du ruisseau Northeast. En 2003, la survie du stock de la rivière Conne était la plus faible jamais enregistrée. Dans quatre rivières sur cinq (l'exception étant la rivière Campbellton), la production de saumoneaux a baissé de 2002 à 2003. Lorsque la production de saumoneaux diminue, on s'attend à ce que la remonte de petits saumons diminue l'année suivante, à moins que la survie en mer augmente de façon à compenser le nombre réduit de saumoneaux. L'inverse s'applique lorsque la production de saumoneaux augmente.

Introduction

This paper presents the general status of Atlantic salmon stocks in Salmon Fishing Areas (SFAs) 3-14A of the Newfoundland Region (Fig. 1) in 2003. Catch and effort data from the recreational fishery, counts and total returns at fishways and counting fences, and egg depositions in relation to conservation requirements are examined in relation to historical data and management measures in effect in 2003.

Management measures, past and present

The moratorium on the commercial Atlantic salmon fishery in insular Newfoundland continued in 2003. The implementation of the moratorium in 1992 was accompanied by a commercial license retirement program and followed a major management plan introduced in 1984 (O'Connell *et al.* 1992a; May 1993; Mullins and Caines MS 1994), elements of which were continued into the quota years of 1990 and 1991 (O'Connell *et al.* MS 1992b) and the moratorium years (1992-2002). These regulations continue a long-standing history of management programs designed to prevent stock declines and to allow populations to rebuild (May 1993).

A quota on the number of small salmon (< 63 cm in fork length) that could be retained in the Atlantic salmon recreational fishery was introduced in each SFA in 1992 and 1993. The quota was assigned for each SFA as a whole as opposed to individual river quotas. Only hook-and-release fishing was permitted after the quota was caught in each SFA. Quotas were eliminated in 1994. The seasonal bag limit for the retention of small salmon was lowered from eight to six fish in 1994, three to be caught prior to July 31 and three after that date. Hook-and-release fishing only was permitted after the bag limit of three was reached in each time period. These measures remained in effect in 1995-1997. Returns of small salmon to many rivers in insular Newfoundland in 1997 were substantially lower than expected (Dempson *et al.* MS 1998; O'Connell *et al.* MS 1998). As a result of this and uncertainties regarding levels of future returns, the management plan for 1998 was much more conservative than for previous years. The seasonal bag limit for the retention of small salmon in insular Newfoundland was reduced to one, pending the results of an in-season review. As a result of the findings of the in-season review, anglers were allowed to additionally retain three small salmon from July 4 until the end of the angling season. Beginning on July 8, 1998 only the use of barbless hooks was permitted. As in previous years, the retention of large salmon (≥ 63 cm in fork length) was not permitted in insular Newfoundland in 2002.

A three-year management plan was implemented in 1999, a significant component of which was the introduction of a River Classification System for insular Newfoundland, used to develop retention levels based on the health of individual stocks, without jeopardising conservation goals. This was a major departure from previous years when stocks were managed on a more regional or SFA basis. Details of the three-year plan and a description of the River Classification System are provided in Anon. (1999). A five-year management plan was introduced in 2002 (Anon. 2002), wherein the River Classification System, though variously modified, was retained.

Special management measures were in effect for several rivers in 2003 and a number of rivers were closed for the season, details of which are provided in Anon. (2003). More details on openings and closures throughout the season on a river-specific basis, including times when rivers were closed due to high water temperatures and low water levels, are presented in Table 1.

As was the case for the period 1995-2002, there were fall hook-and-release fisheries (September 8-October 7) in Gander River (SFA 4) and in Humber River (SFA 13) in 2003. A fall fishery was also introduced for Exploits River in 2002 and continued in 2003 with the same opening and closure dates as for Gander and Humber rivers applying.

For the five-year period immediately preceding the commercial salmon fishery moratorium, the average number of recreational fishery licenses sold in Newfoundland and Labrador was 24493. Maximum license sales prior to the moratorium were recorded in 1988 (26445). By comparison, sales during the moratorium years were as follows:

Year	Licenses sold
1992	25718
1993	26508
1994	22596
1995	21489
1996	25553
1997	21403
1998	18490
1999	17927
2000	17244
2001	17876
2002	15937
2003 (preliminary)	16000

There has been a significant overall decline ($P = 0.0000$) in the numbers of licenses sold since 1992 ($y = -986.34x + 0.000022$; $r^2 = 0.847$).

Methods

Fishway, counting fence, swim-through survey (five rivers in Bay St. George), and egg deposition data were added to that presented in O'Connell *et al.* (MS 2003). Recreational fishery data are provided for the period 1994-2003 and were derived from the License Stub Return System. The information for 2003 is preliminary at this stage. Recreational fishing effort was presented as rod days, defined as any day or part of a day on which an angler fishes.

Recreational fishery catch and effort data in 2003 were compared to means for 1994-2002. Counts, total returns (which typically are counts at counting facilities or from

swim-through surveys plus angling removals below counting facilities or before swim-through surveys plus an adjustment for hook-and-release mortality), and percent of conservation egg requirement achieved in 2003 were compared to the pre-salmon moratorium mean 1984-1991. This mean involves the years 1984-1989 in which there were major management changes in the commercial fishery in the Newfoundland Region (O'Connell *et al.* 1992a) and includes 1990 and 1991 when quotas were in effect in each SFA in insular Newfoundland (O'Connell *et al.* MS 1992b). The mix of management measures in effect during 1984-1989 on the one hand and the imposition of commercial quotas in 1990 and 1991 on the other, should be kept in mind when making evaluations involving the pre-moratorium mean. Two means were used for the moratorium years, 1992-1996 and 1997-1992. The first corresponds to the period when fish otherwise caught in the commercial fishery escaped to rivers thereby increasing spawning escapements in many rivers, while the second is the period during which the progeny of the increased spawners were to return (see also below).

References for river-specific methodologies used for the calculation of total river returns of small and large salmon and percent of conservation egg requirement achieved can be found in CSAS (2001, 2002a, 2002b, 2003). **Since recreational fishery data were not finalized for 2003, total returns and percent of conservation egg requirement achieved values are still preliminary where appropriate.**

Means and 95% confidence intervals for ratios were calculated according to Cochran (1977).

Results and Discussion

Smolt-to-adult (small salmon) survival

The smolt-to-adult survival (repeat spawners included) of 6.8% for Campbellton River in 2003 (adult year) increased over 2002 (Table 2); the highest survival for this river occurred in 1994 (9.0%). A survival of 5.5% was observed for Northeast Brook, Trepassey (SFA 9) in 2003, a decrease from that of 2002, which in turn was the highest since 1996. Rocky River (SFA 9) recorded a survival of 4.0% in 2003, an improvement over that of 2002. Survival for Conne River (SFA 11) in 2003 (2.4%) was the lowest on record, markedly below the 8.1% achieved in 2000. The highest survival for Conne River (10.2%) was reached in 1988. There were no smolt counts for Highlands River since 2001 and hence survival cannot be determined. Survival for Western Arm Brook (SFA 14A) in 2003 (9.4%) improved slightly over 2002 and was the second highest of the moratorium years (the record high of 12.1% occurred in the pre-moratorium year 1979).

Fig. 2 shows graphically trends in sea survival for the rivers mentioned above. Survival adjusted for marine exploitation (from Dempson *et al.* MS 1998) is also shown for Conne River, Northeast Brook, Trepassey, and Western Arm Brook. During the moratorium years, estimates of sea survival from smolts to adult small salmon are assumed to represent natural survival rates. Pre-moratorium adjusted (for commercial harvest)

survival rates approaching 15% were achieved in Conne River and Northeast Brook, Trepassey. Ocean survival for both of these stocks fell throughout the late 1980s and early 1990s. Despite major changes to fisheries and corresponding reductions in marine exploitation, sea survival rates for Conne River and Northeast Brook, Trepassey remain low, as highlighted by the adjusted sea survival rates. The same statement holds for Western Arm Brook, if several years prior to 1985 (the earliest year shown in Fig. 2) presented in Table 2 were adjusted for marine exploitation.

Smolt production

The number of smolts counted at Northeast Brook, Trepassey in 2003 was approximately one-half the record number counted in 2002. Declines from 2002 were also noted for Rocky River (56%), Conne River (4%), and Western Arm Brook (19%) while Campbellton River showed an increase (8%).

Recreational fishery, counts, and total returns

Recreational catches of small and large salmon for insular Newfoundland (SFAs 3-14A combined) are presented in Appendix 1a. Data for insular Newfoundland were also rolled into four subdivisions, Northern Peninsula East and Eastern (SFAs 3-8), South (SFAs 9-11), Southwest (SFAs 12-13), and Northern Peninsula West (SFA 14A) and are shown in Appendix 1b-e. Data for each individual SFA are shown in Appendix 1f-q. Calculation of catch per unit of effort (CPUE) is in terms of small and large retained and released fish combined. Counts of small and large salmon and associated pre-moratorium and moratorium means are presented in Tables 3 and 4.

Entire Insular Newfoundland (SFAs 3-14A)

Recreational fishery

The total catch of small salmon (retained + released fish) and retained catch of small salmon in 2003 were the lowest of the time series (Fig. 3). The number of large salmon released was similar to 2002 and remained well below the 1994-2002 mean. Effort was also similar to 2002 and below average. Catch per unit of effort (CPUE) in 2003 decreased from the above average level of 2002.

Northern Peninsula East and Eastern (SFAs 3-8)

Recreational fishery

Total and retained catches of small salmon in 2003 were similar to 2002 and remained below the 1994-2002 means (Fig. 4). The number of large salmon released and effort expenditure were the lowest recorded. CPUE was similar to 2002 and slightly above average.

Total returns – northeast coast

SFA 3: The counting fence in Northwest Branch tributary of Main River (Sop's Arm) has not operated since 1999.

SFA 4: Information on total returns of small (Table 5 and Fig. 5) and large (Table 6 and Fig. 5) salmon is available for Exploits River (Bishop's Falls), Gander River, and Campbellton River. Returns of small salmon to Exploits River in 2003 increased over 2002 and all means (Table 7) while returns of large salmon increased over 2002 and all means except that of 1992-2002 where there was no change (Table 8). Returns of small salmon to Campbellton River in 2003 showed a slight increase over 2002 and were similar to the mean for 1997-2002, but below the 1992-1996 mean. Returns of large salmon in 2003 increased over 2002 but remained below the means. Returns of small salmon to Gander River in 2003 were similar to 2002 and the 1997-2002 mean and well above the 1984-1991 mean, but below the 1992-1996 mean. Returns of large salmon were similar to 2002 and the 1992-1996 mean, above the 1984-1991 mean, and below the 1997-2002 mean.

The proportion of large salmon in total returns to Exploits River in 2003 decreased from 2002 and the 1997-2002 mean, increased over the 1984-1991 mean, and was similar to the 1992-1996 mean (Table 9 and Fig. 6). The proportion for Campbellton River increased slightly over 2002 but remained below the means while for Gander River the proportion in 2003 was similar to that of 2002, above the means for 1984-1991 and 1992-1996 but below the mean for 1997-2002.

Total returns – east coast

SFA 5: Information on total returns of small (Table 5 and Fig. 7) and large (Table 6 and Fig. 7) salmon is available for Middle Brook, the lower Terra Nova River, and Northwest River, Terra Nova National Park. Returns of small salmon to Middle Brook in 2003 increased over 2002 and were similar to the 1984-1991 mean, but declined from the means for 1992-1996 and 1997-2002 (Table 7). Returns of large salmon were similar to 2002, showed an increase over the 1984-1991 mean, but remained below the 1992-1996 and 1997-2002 means (Table 8). Returns of small salmon to lower Terra Nova River increased over 2002 and all means except that of 1992-1996 which showed no change. Returns of large salmon increased over 2002 and the 1984-1991 mean, remained below the 1992-1996 mean and were similar to the 1997-2002 mean. Returns of both small and large salmon to Northwest River in 2003 increased over 2002 and the means.

Proportions of large salmon in total returns to Middle Brook and Terra Nova River in 2003 decreased from 2002, increased over the means for 1984-1991, but decreased from the means for 1992-1996 (except for Middle Brook which remained similar) and 1997-2002 (Table 9 and Fig. 8). The proportion for Northwest River was similar to 2002 and slightly below the means.

South (SFAs 9-11)

Recreational fishery

Total and retained catches of small salmon, the number of large salmon released, and effort expenditure in 2003 were among the lowest recorded (Fig. 9). CPUE, however, was average.

Total returns

SFA 9: Information on total returns of small (Table 5 and Fig. 10) and large (Table 6 and Fig. 10) salmon is available for Northeast Brook, Trepassey and Rocky River. Total returns of small salmon to Northeast Brook in 2003 increased over 2002 and the means (Table 7). Returns of large salmon increased over 2002 and were similar to the mean for 1997-2002, but decreased from the means for 1984-1991 and 1992-1996 (Table 8). Returns of small salmon to Rocky River in 2003 also increased over 2002 and the means. Large salmon returns were similar to 2002, decreased relative to the 1997-2002 mean but increased over the 1984-1991 and 1992-1996 means.

The proportion of large salmon in total returns to Northeast Brook in 2003 increased over 2002 but remained below the means (Table 9 and Fig. 11). The proportion for Rocky River decreased from 2002 and the 1997-2002 mean and increased over the means for 1984-1991 and 1992-1996 (slightly).

SFA 11: Information on total returns of small (Table 5 and Fig. 10) and large (Table 6 and Fig. 10) salmon is available for Conne River and Little River. Returns of small salmon to Little River in 2003 decreased from 2002 and the 1997-2002 mean but remained above the means for 1984-1991 and 1992-1996 (Table 7). Returns of large salmon decreased relative to 2002 and all means except that of 1984-1991 which showed an increase (Table 8). Returns of both small and large salmon to Conne River in 2003 decreased from 2002 and all means.

The proportions of large salmon in total returns to Little River and Conne River in 2003 decreased from 2002 and all means (Table 9 and Fig. 11).

Southwest (SFAs 12-13)

Recreational fishery

Total catch of small salmon in 2003 decreased from 2002 and the mean while the number of small salmon retained was average (Fig. 12). The number of large salmon released increased over 2002 but remained below the mean. Effort expenditure increased over 2002 and was about average while CPUE on the other hand was the lowest on record.

Total returns

SFA 13: Information on total returns of small (Table 5 and Fig. 13) and large (Table 6 and Fig. 13) salmon is available for Highlands River, Crabbes River, Middle Barachois River, Robinsons River, Fischells River, Flat Bay Brook, and Harry's River. All rivers had increases in returns of small salmon in 2003 compared to 2002 except Flat Bay Brook which remained similar (Table 7). Returns of large salmon to Highlands River, Crabbes River, Fischells River, and Harry's River in 2003 increased relative to 2002 while the remaining rivers had decreases (Table 8). For both small and large salmon, Highlands and Harry's rivers showed increases over the 1992-1996 means and compared to the 1997-2002 means, all rivers except Middle Barachois, Robinsons, and Flat Bay had increases.

Proportions of large salmon in total returns in 2003 increased over 2002 for Highlands, Crabbes, Fishells, and Harry's rivers but decreased in the remainder (Table 9 and Fig. 14). Compared to the means, all but Fischells and Harry's rivers had declines.

Northern Peninsula West (SFA 14A)

Recreational fishery

Total and retained catches of small salmon and the number of large salmon released in 2003 decreased from 2002 and the means (Fig. 15). Effort expenditure increased over 2002 though still below the mean while CPUE went from above average in 2002 to below average in 2003.

Total returns

Information on total returns of small (Table 5 and Fig. 16) and large (Table 6 and Fig. 15) salmon is available for Lomond River, Torrent River, and Western Arm Brook. Returns of small salmon to Lomond River in 2003 were similar to 2002 and the 1997-2002 mean and increased over the 1984-1991 mean, but decreased from the 1992-1996 mean (Table 7). A similar pattern was shown by large salmon with the exception that returns in 2003 increased over 2002 (Table 8). Returns of small and large salmon to Torrent River in 2003 decreased from 2002 and the 1992-1996 and 1997-2002 means but remained above the 1984-1991 mean. Returns of small salmon to Western Arm Brook in 2003 were similar to 2002 and above the means while large salmon showed a decrease relative to 2002 but remained above the means.

The proportion of large salmon in total returns to Lomond River in 2003 increased over 2002 and the 1984-1991 and 1992-1996 means but was similar to the mean for 1997-2002 (Table 9 and Fig. 17). The proportion for Torrent River was similar to 2002, above the 1984-1991 and 1992-1996 means, but below the mean for 1997-2002. Except in relation to the 1984-1991 mean, the proportion for Western Arm Brook declined.

Net marks

The incidence of net-marked fish has been determined at counting facilities for a number of rivers throughout insular Newfoundland since 1994. The results for small and large salmon combined are presented below:

River	1994	1995	1996	1997	1998	1999	2000	2001	2002	2003
Gander River	15.9	8.9	12.2	15.9	2.9	5.2	3.9	3.7	3.0	4.6
Campbellton River	6.2	5.0	4.3	4.3	5.8	4.1	11.4	4.9	3.7	7.5
Middle Brook				15.8	11.6	4.5	7.7	3.0	7.0	4.2
Terra Nova River				2.9	1.2	3.1		4.8	4.1	3.0
Northeast Riv., Plac.							7.5			
Conne River	18.6	7.1	6.2	7.2	3.7	4.0	3.3	8.0	2.6	6.1
Harry's River			0.6	9.3	1.8	0.1	2.6			
Humber River		1.4	2.6	7.6	4.1	2.4				

The incidence of marked fish in 2003 increased over the record low of 2002 for Campbellton River. It should be noted that, unlike the other rivers, marks recorded for Campbellton River include all marks (e.g. resulting from encounters with predators, etc.) and not just net marks. Fish were counted with a video system in this river and it is not possible to accurately distinguish the various markings. It was possible to determine the incidence of net marks for the remaining rivers. After 1999, values for Gander River were determined at the fishway in Salmon Brook tributary and at the counting fence in other years; the incidence for 2003 was the highest since 1999. For Middle Brook and Terra Nova River, there was a decrease relative to 2002, being most pronounced for Middle Brook. Conne River showed an increase over 2002. Net marks were likely the result of encounters with both legally set gear for other species and illegal gear in the marine environment and with illegal gear in freshwater. It is not possible to estimate the extent of such removals, therefore, total returns considered in the context of being equivalent to total production during the moratorium, have to be regarded as minimum values.

Percent of conservation egg requirement achieved

Northern Peninsula East and Eastern (SFAs 3-8)

Northeast coast, SFA 4

The Exploits River as a whole achieved just over half of its conservation egg requirement in 2003 while the lower Exploits segment exceeded requirement (Table 10 and Fig. 18); the middle and upper Exploits remained well below requirement, being most pronounced for the latter. Percent achieved in 2003 exceeded 2002 for the whole Exploits and for all segments separately; with the exception of the upper Exploits, this also applied in relation to the means. It should be noted that values included in the pre-moratorium

mean (1984-1991) for the upper Exploits were the result of artificial stocking of this segment while egg deposition in subsequent years resulted from natural spawning of adults ascending the Red Indian Lake fish passage. The Exploits River was the site of major Atlantic salmon enhancement programs beginning in the late 1950s and extending to the early 1990s (O'Connell *et al.* 1983; O'Connell and Bourgeois 1987; Bourgeois *et al.* MS 2001).

Egg deposition in Campbellton River exceeded conservation requirement in all years. The percent met in 2003 increased over the record low observed in 2002 but was below the means.

Gander River has not attained conservation requirement since 1999. The percent achieved in 2003 decreased from 2002 and the moratorium means but remained above the pre-moratorium mean.

East coast, SFA 5

Middle Brook achieved conservation egg requirement in all years of the moratorium. The percent achieved in 2003 increased over the moratorium low of 2002 and the pre-moratorium mean, but remained below the moratorium means.

Terra Nova River has yet to attain egg requirement. It should be noted however that accessible habitat for anadromous Atlantic salmon in this river more than doubled with the establishment of a fish passage at Mollyguajeck Falls in 1985, as part of an enhancement initiative that started in that year (O'Connell *et al.* MS 2000). Initial enhancement activity started in 1952 with the construction of a fishway around impassable falls in the upper river (O'Connell *et al.* MS 2000; Mullins *et al.* 2003). The level of attainment of egg requirement in 2003 was the highest since 1995, surpassing 2002 and the means.

The percent of egg requirement reached in Northwest River in 2003 was the highest on record. In 1948, the area above Northwest Falls was made accessible to anadromous salmon with the blasting of a fish passage (Cote *et al.* 2001). Prior to 1948 only the first 3.2 km of the river were accessible.

Data for Indian Bay Brook are only available for 1997-1999 and conservation egg requirement was achieved in all years.

South (SFAs 9-11)

SFA 9

There is no information available for Biscay Bay River since 1996. Northeast Brook, Trepassey has reached egg requirement in all years of record. The level achieved in 2003 was the highest since 1986, well above 2002 and the means.

Rocky River was the recipient of Atlantic salmon enhancement initiatives during the period 1984-1996 which included an operational fishway around an impassable waterfall at the mouth (Bourgeois 1998; Mullins *et al.* 2003). This river achieved half of its egg requirement in 2003, which was an increase over 2002 and the means.

SFA 10

For the first time, there was no information available for Northeast River, Placentia in 2003. This river exceeded egg requirement in all years.

SFA 11

Little River attained egg requirement in 2003. The level decreased from 2002 and the 1997-2002 mean, but increased over the 1984-1991 and 1992-1996 means. This system was stocked with swim-up fry in the 1980s and 1990s (Bourgeois *et al.* MS 1997).

The level of egg requirement met in Conne River in 2003 was one of the lowest on record, below 2002 and the means.

Southwest (SFAs 12-13)

SFA 13

Of the seven rivers with data available for 2003, only Highlands River and Flat Bay Brook virtually achieved egg requirement (99%). Compared to 2002 and the 1992-1996 means, all rivers increased (except Middle Barachois which remained the same in relation to 2002). Highlands, Crabbes, Fischells, and Harry's rivers increased over the 1997-2002 means while the remainder had decreases.

There is no information available for Pinchgut Brook for 2003 or for Humber River since 1999.

Northern Peninsula West (SFA 14A)

Lomond River achieved egg requirement in 2003. Compared to 2002 and the pre-moratorium mean there was an increase but in relation to the moratorium means there were decreases.

Torrent River likewise achieved egg requirement in 2003, decreasing from 2002 and the moratorium means while increasing over the pre-moratorium mean. An enhancement program was carried out in this river in 1965-1976, which included the construction of a fishway around an impassable waterfall located 2 km from the mouth (Mullins *et al.* 2003).

Egg requirement was achieved in Western Arm Brook in 2003; there was a decrease compared to 2002 but an increase in relation to the means.

Summary and Conclusions

Returns of small and large salmon in 2003 improved over 2002 (a below average year) for most rivers. However, many rivers declined or remained similar in comparison to the moratorium means. The proportion of large salmon in total returns decreased from 2002 and the moratorium means for most rivers. Greatly increased spawning escapements in most rivers on the northeast, northwest, and east coasts in 1992-1996, immediate benefits of the moratorium, should have resulted in corresponding increases in small salmon recruitment beginning in 1997 and 1998 (depending on smolt age composition). This has not occurred and in fact, except for Western Arm Brook, average returns in 1997-2002 were lower than in 1992-1996. Some rivers in southern Newfoundland did not receive the same immediate benefits from the closure of the commercial fishery as was evident in northern areas and indeed returns of small salmon were lower during moratorium years than prior to the moratorium in Northeast Brook, Trepassey and Conne River. With respect to large salmon, with only a few exceptions (Northwest River, Northeast Brook, Trepassey, and Conne River), returns during the moratorium years showed an overall increase relative to pre-moratorium years, and for most, average returns in 1997-2002 were higher than in 1992-1996. Prior to the closure of the commercial salmon fishery, marine exploitation rates for the period 1984-1991 averaged 45.3% on small salmon and 74.2% on large salmon (Dempson *et al.* 2001). In spite of the closures and restrictions placed on fisheries since 1992, overall abundance continues to be low.

Conservation egg requirements were met or exceeded in only ten out of 24 rivers or sections of rivers in 2003. It should be noted that rivers that have undergone enhancement activities in the past 10-20 years (Exploits, Terra Nova, and Rocky), resulting in the opening up of vast amounts of habitat, are still in the developmental stage and are not expected to achieve conservation requirements in the near future.

Virtually all rivers in insular Newfoundland were closed to angling for varying periods (mainly in August) in 2003, due to low water levels and high water temperatures (Table 1). This most likely affected angling effort and catches to some extent (historically, most angling activity and the bulk of catches occur in June-July). For insular Newfoundland overall (Fig. 3), catches of small and large salmon, effort, and the catch rate in 2003 were below average.

Sea survival in 2003 increased over 2002 in three of the five rivers with smolt and adult counts. For Conne River, sea survival in 2003 was the lowest on record. Smolt production decreased from 2002 in four of the five. When smolt production decreases, returns of small salmon are expected to be lower in the following year, unless correspondingly there are increases in marine survival that offset decreased numbers of smolts. The converse holds when there are increases in smolt production.

Table 4. Counts of large salmon from fishways and counting fences in insular Newfoundland 1974-2003 by Salmon Fishing Area (SFA). Also shown are means, coefficients of variation, 95% confidence limits (LCL and UCL), and percentage change for 2003 in relation to 2002, and the 1984-1991, 1992-1996, and 1997-2002 means. Partial counts are in parentheses and are not included in statistical calculations. Adjusted counts are bold.

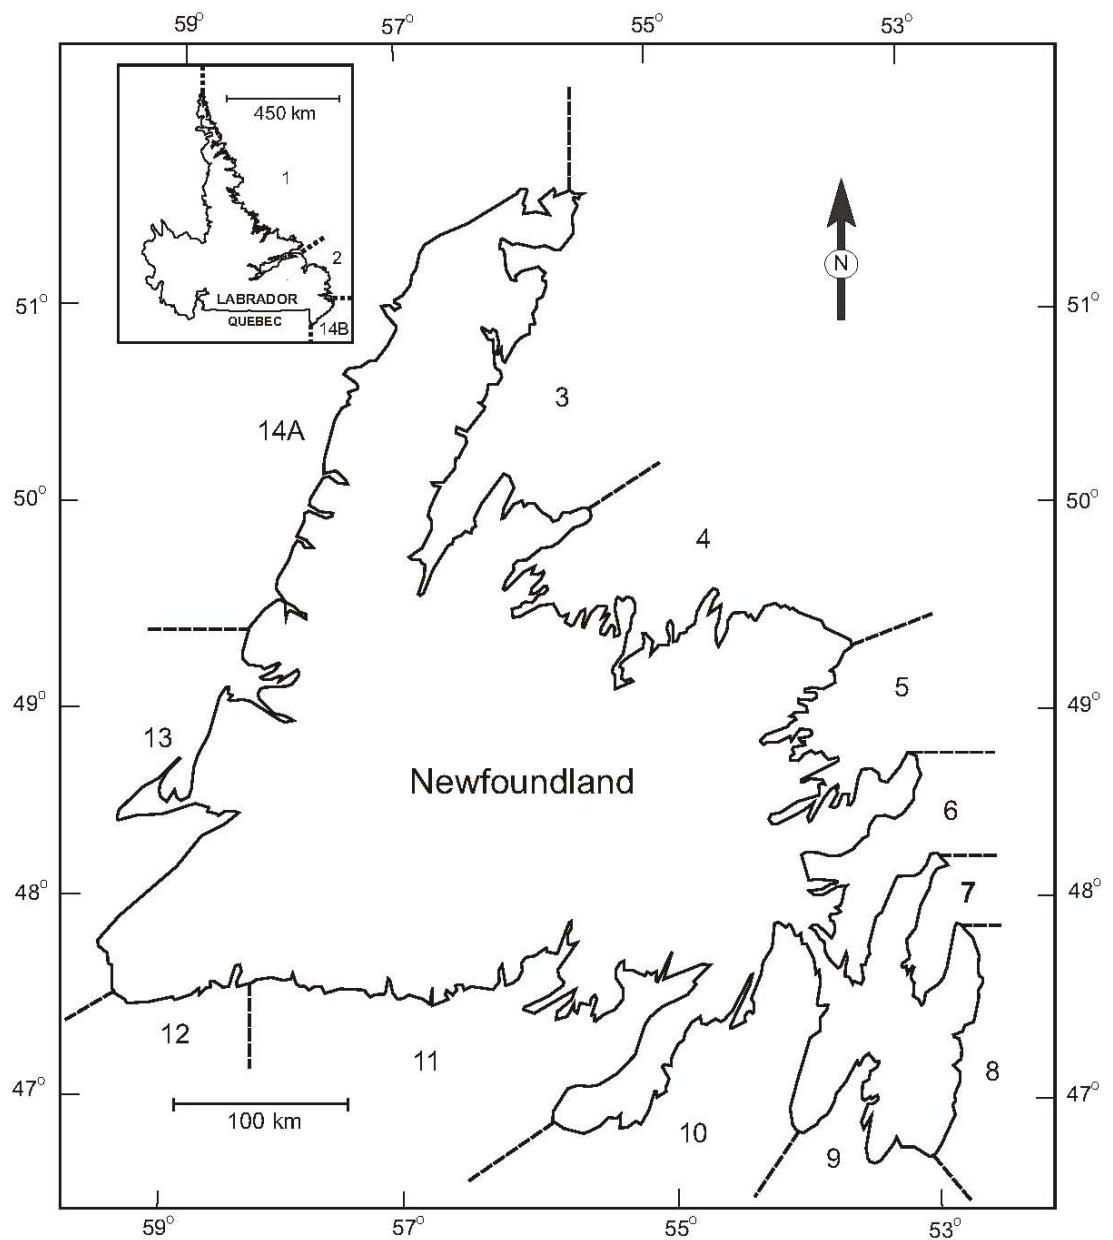

Fig. 1. Map showing the 14 Salmon Fishing Areas of the Newfoundland Region.

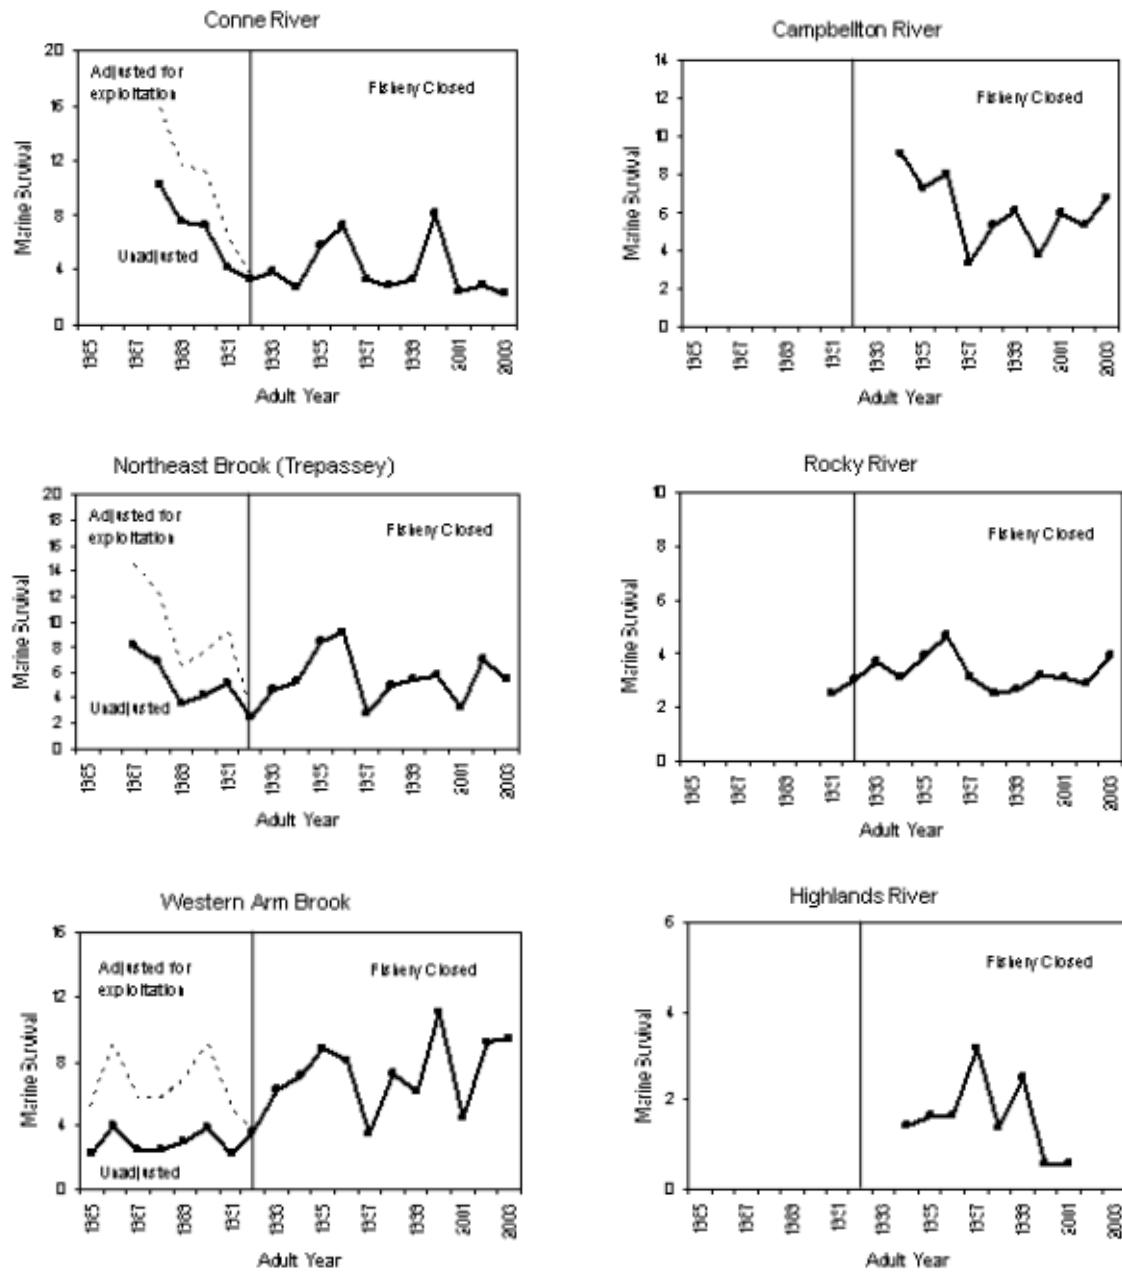

Fig. 2. Estimates of marine survival from smolts in year i to adult small salmon in year $i+1$. Dashed line represents marine survival adjusted for average marine exploitation rate (from Dempson et al. MS 1998).

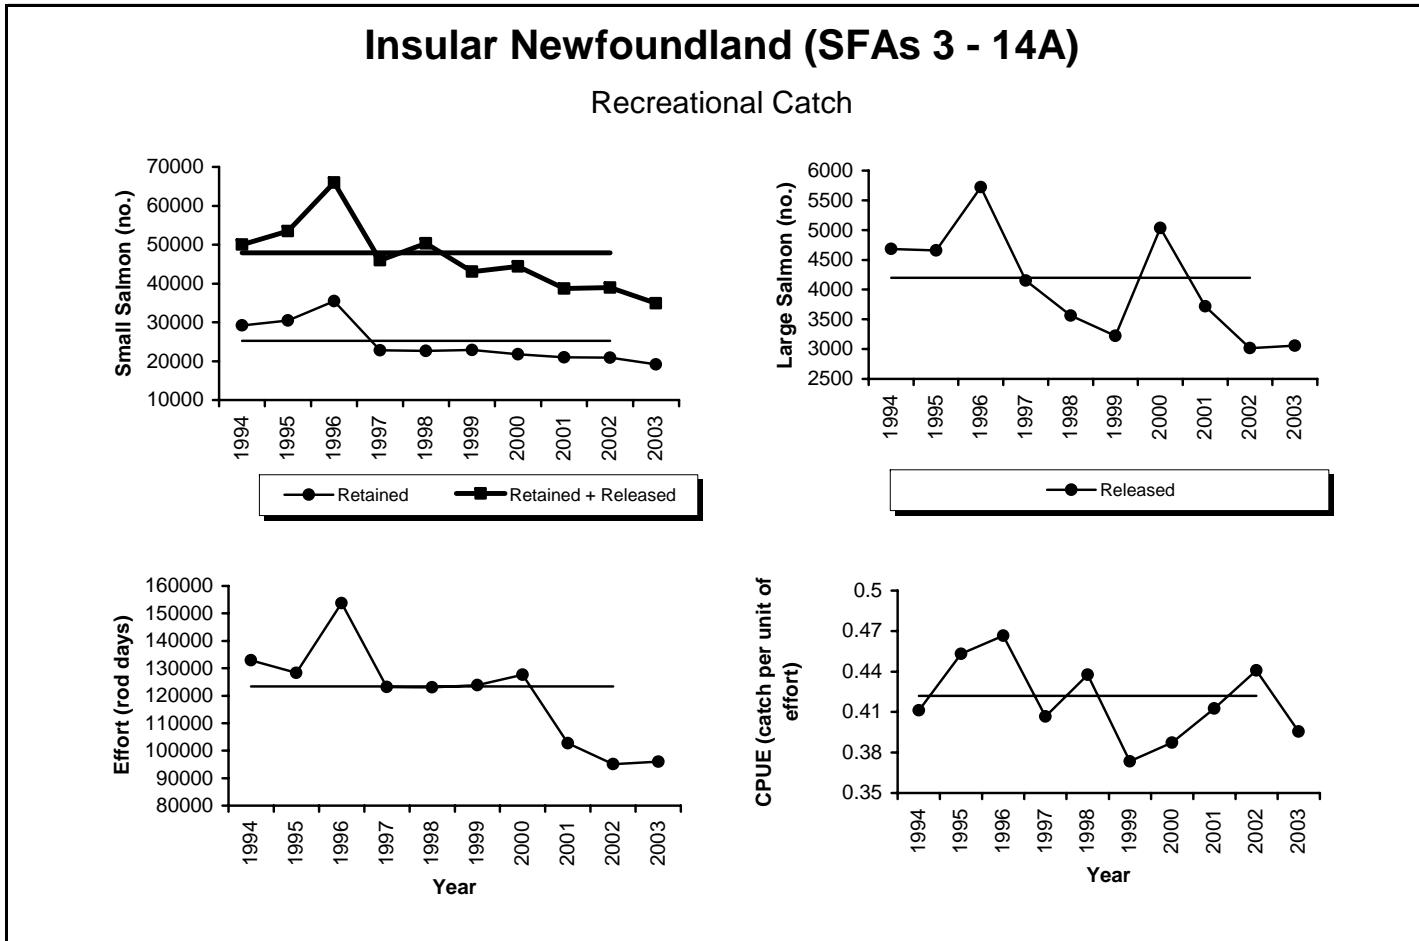

Fig. 3. Recreational catch of small salmon (retained and retained plus released), large salmon released, effort, and CPUE, 1994-2003, for Insular Newfoundland (SFAs 3-14A). The thin horizontal line represents the 1994-2002 mean for small salmon retained, large released, effort and CPUE, and the thick horizontal line the 1994-2002 mean for retained and released small salmon combined.

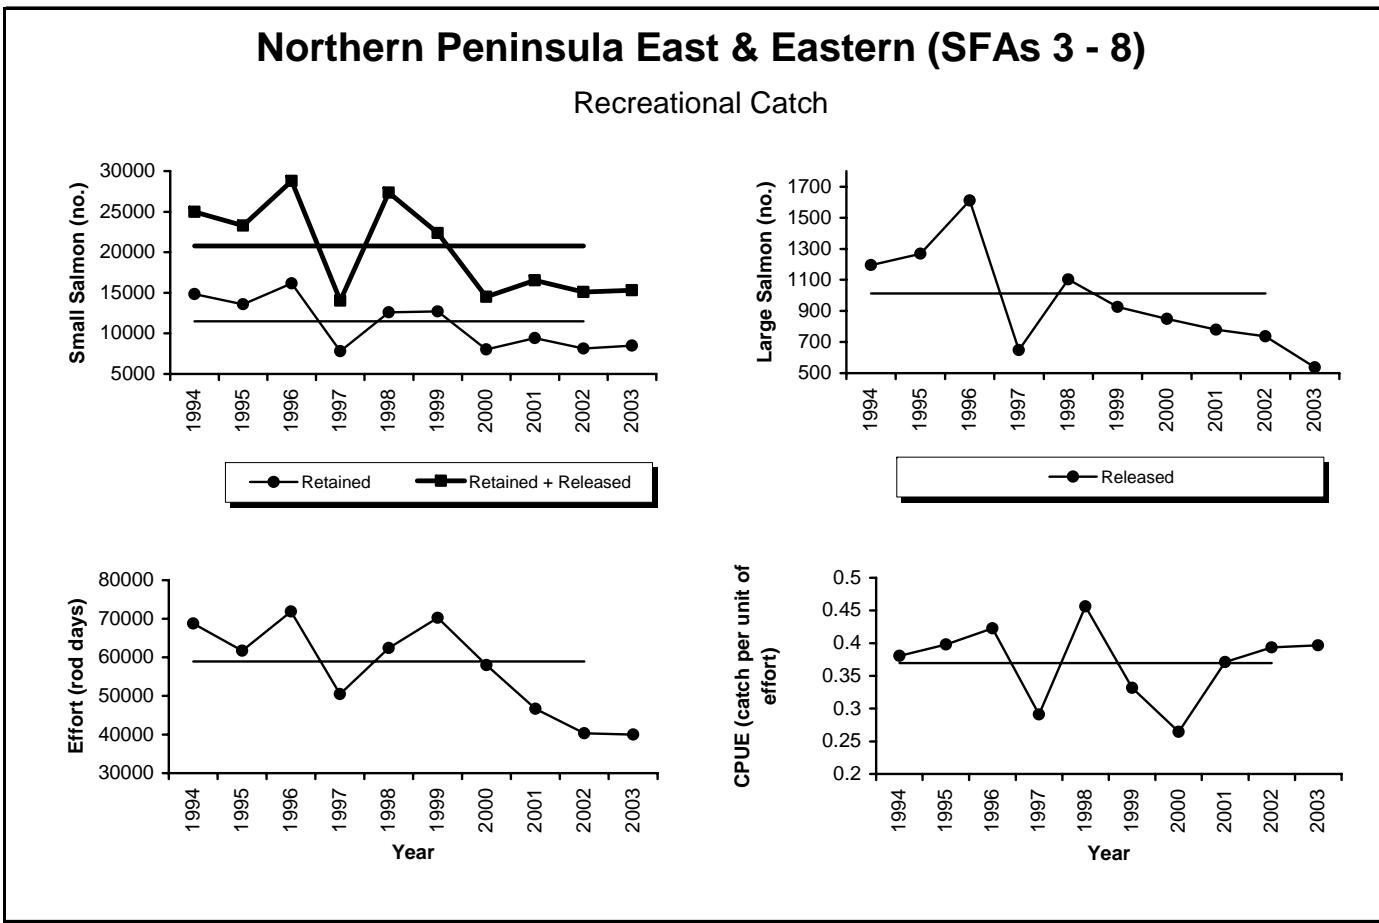

Fig. 4. Recreational catch of small salmon (retained and retained plus released), large salmon released, effort, and CPUE, 1994-2003, for Northern Peninsula East & Eastern (SFAs 3-8). The thin horizontal line represents the 1994-2002 mean for small salmon retained, large released, effort and CPUE, and the thick horizontal line the 1994-2002 mean for retained and released small salmon combined.

NORTHEAST COAST

Total Returns

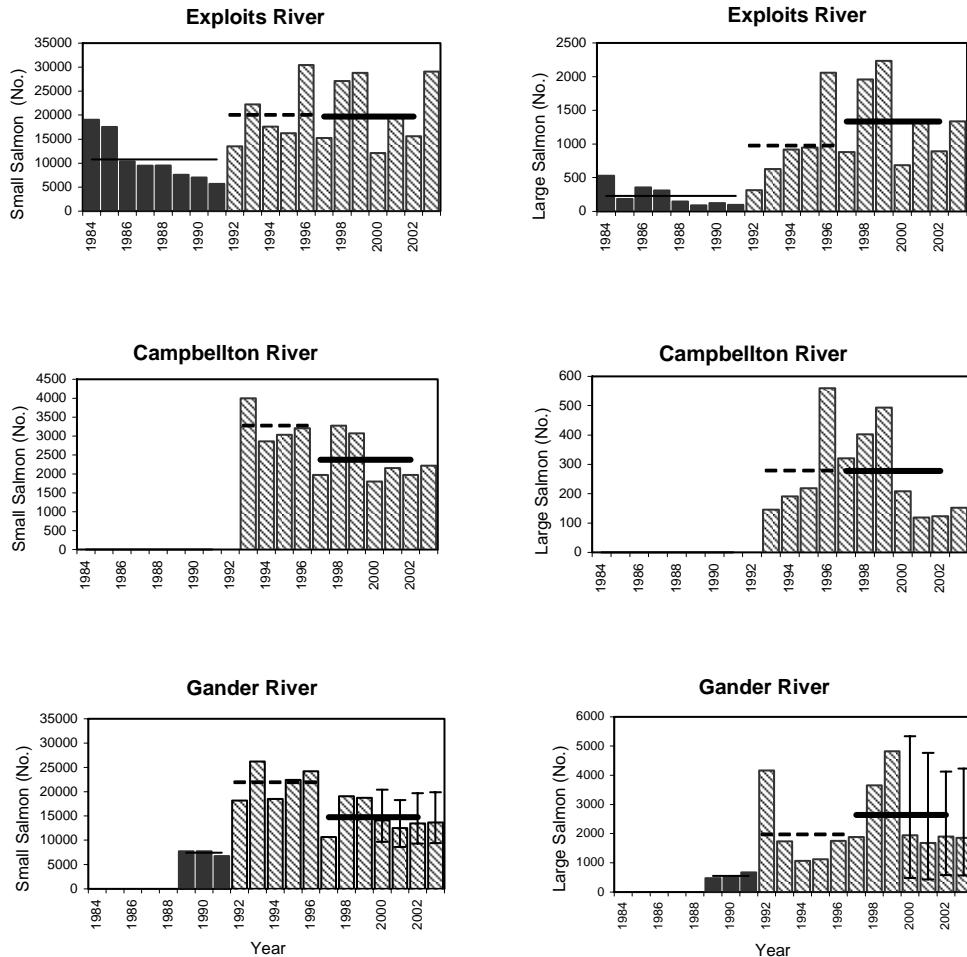

Fig. 5. Total returns of small and large salmon to Exploits River, Campbellton River and Gander River (northeast coast), 1984-2003. The thin solid horizontal line represents the 1984-1991 mean, the broken line the 1992-1996 mean, and the thick solid line the 1997-2002 mean. The dark gray bars represent the pre-moratorium years and the cross-hatched bars the moratorium years. Vertical lines are estimates of the 5th to 95th percentiles.

Northeast Coast

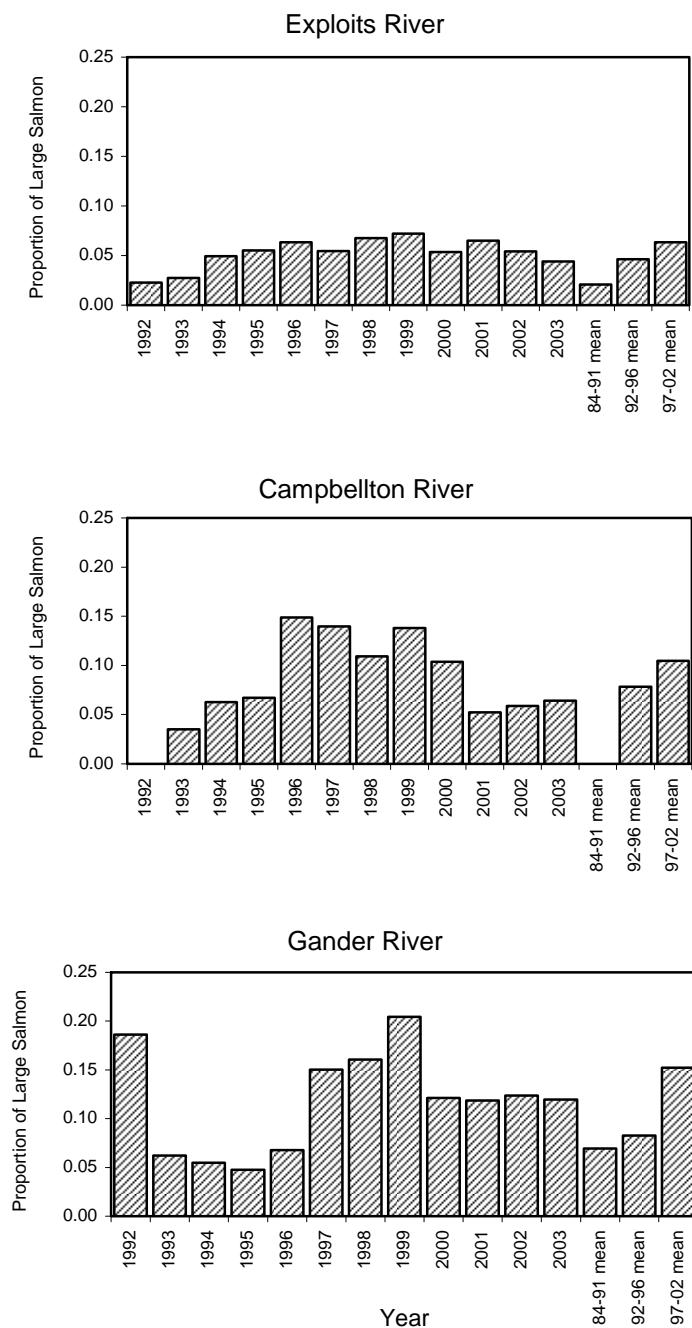

Fig. 6. Proportion of large salmon in total returns to Exploits River, Campbellton River and Gander River, (northeast coast), 1992-2003, and the 1984-1991, 1992-1996 and 1997-2002 means.

EAST COAST Total Returns

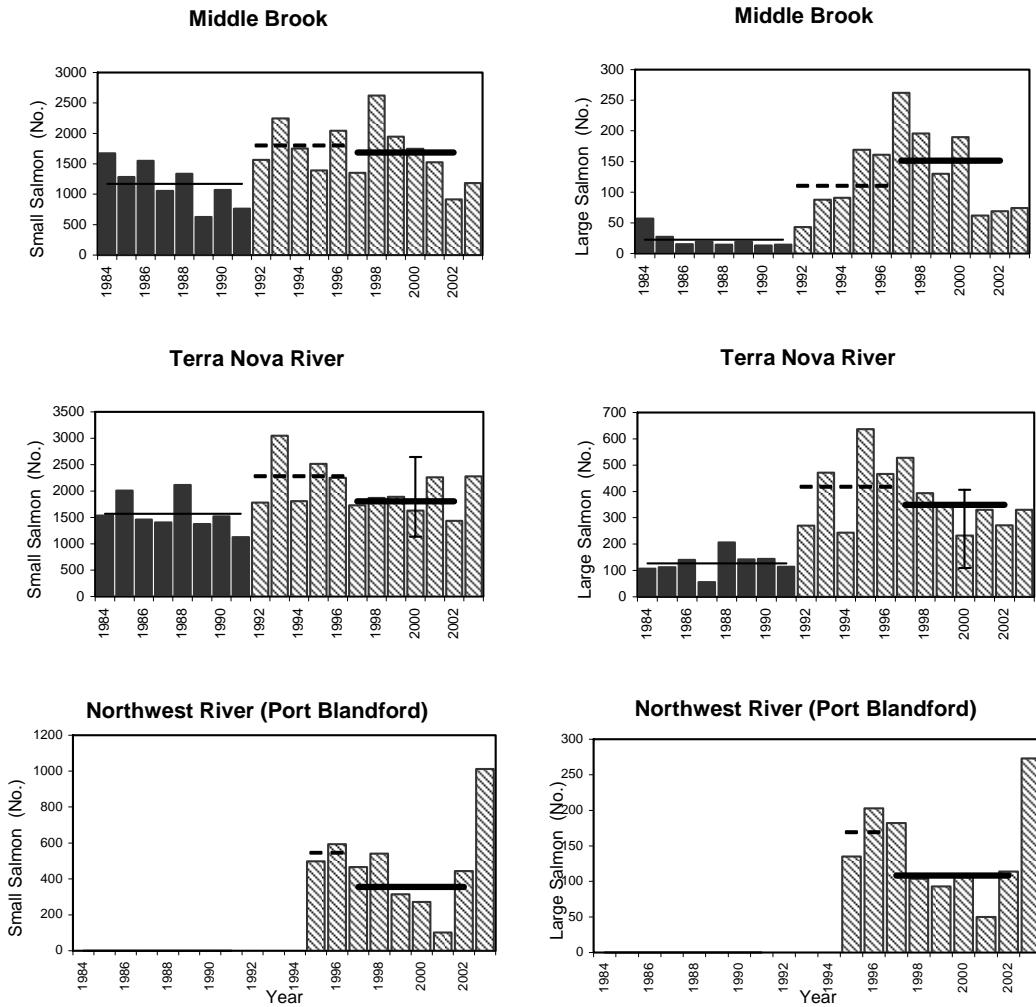

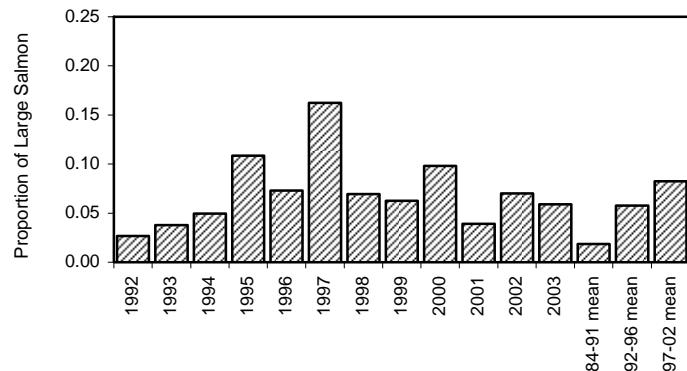

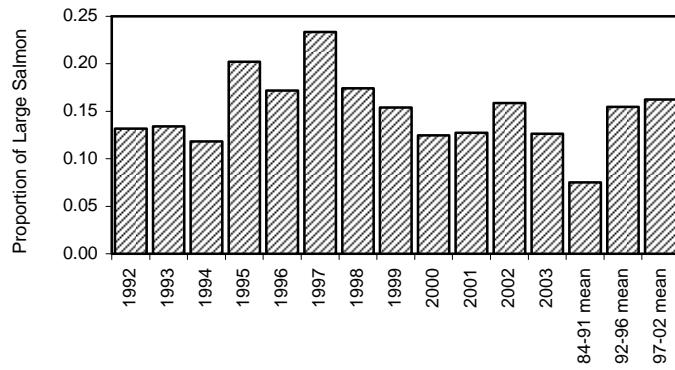

Fig. 7. Total returns of small and large salmon to Middle Brook, Terra Nova River and Northwest River, Port Blandford (east coast), 1984-2003. The thin solid horizontal line represents the 1984-1991 mean, the broken line the 1992-1996 mean, and the thick solid line the 1997-2002 mean. The dark gray bars represent the pre-moratorium years and the cross-hatched bars the moratorium years. Vertical lines are estimates of the 5th to 95th percentiles.

East Coast

Middle Brook

Terra Nova River

Northwest River (Port Blandford)

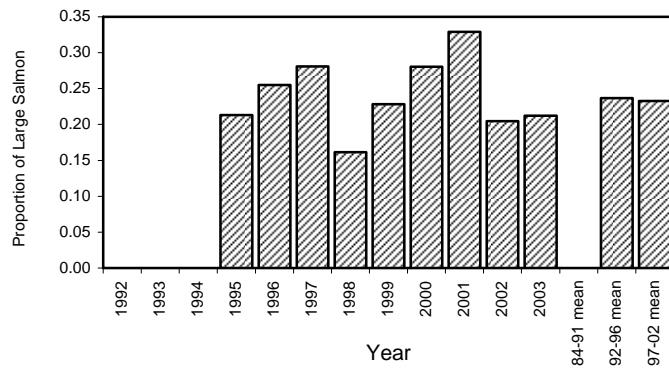

Fig. 8. Proportion of large salmon in total returns to Middle Brook, Terra Nova River and Northwest River, Port Blandford, (northeast coast), 1992-2003, and the 1984-1991, 1992-1996 and 1997-2002 means.

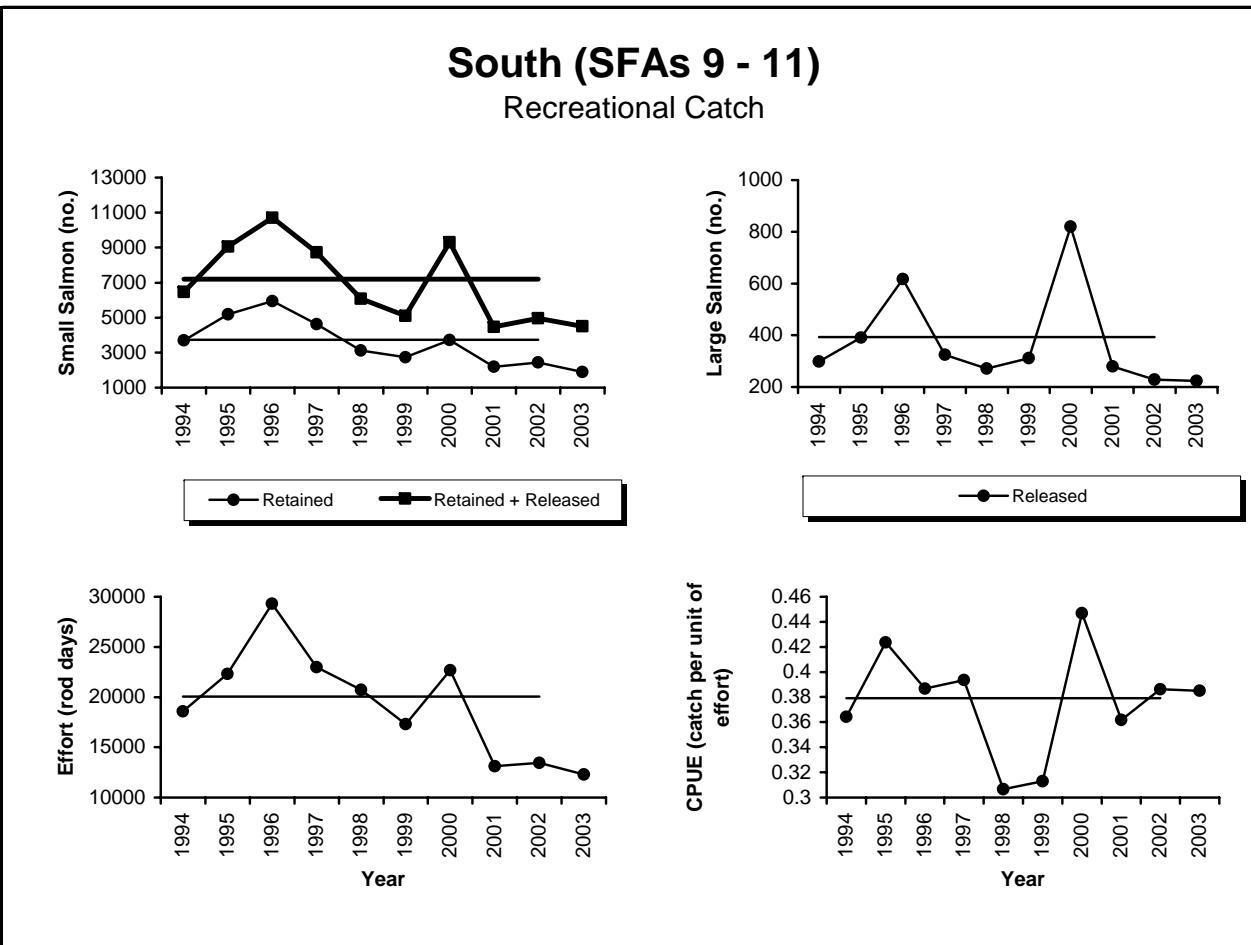

Fig. 9. Recreational catch of small salmon (retained and retained plus released), large salmon released, effort, and CPUE, 1994-2003, for South (SFAs 9-11). The thin horizontal line represents the 1994-2002 mean for small salmon retained, large released, effort and CPUE, and the thick horizontal line the 1994-2002 mean for retained and released small salmon combined.

SOUTH COAST Total Returns

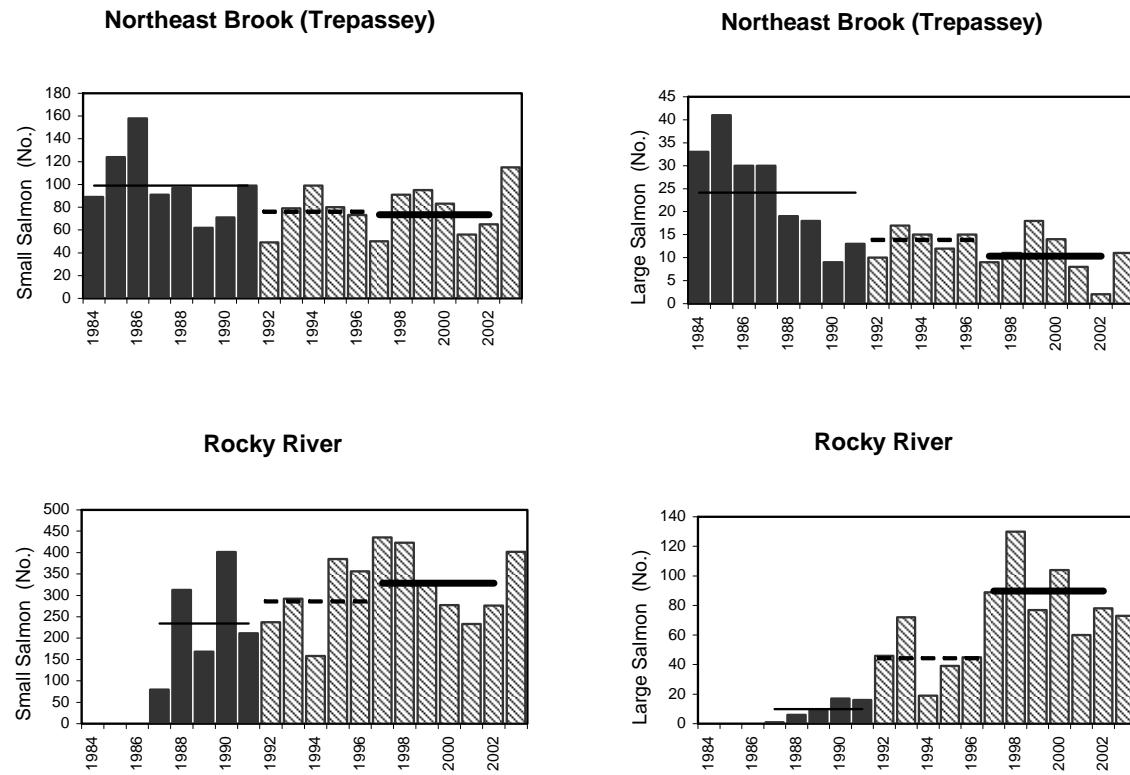

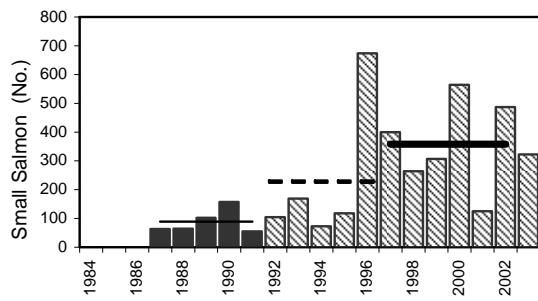

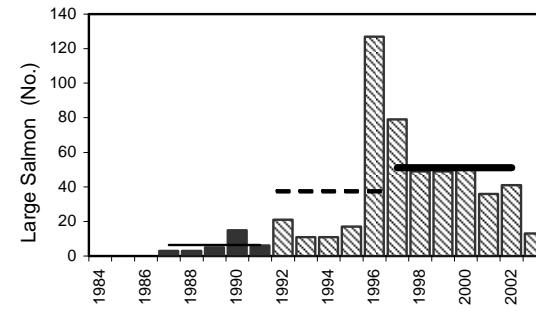

Fig. 10. Total returns of small and large salmon to Northeast Brook (Trepassey), Rocky River, Little River and Conne River (south coast), 1984-2003. The thin solid horizontal line represents the 1984-1991 mean, the broken line the 1992-1996 mean, and the thick solid line the 1997-2002 mean. The dark gray bars represent the pre-moratorium years and the cross-hatched bars the moratorium years. Vertical lines are estimates of the 5th to 95th percentiles.

SOUTH COAST Total Returns

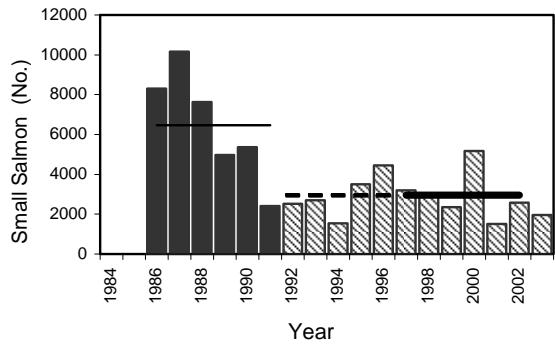

Little River

Little River

Conne River

Conne River
