#### Abstract

* This series documents the scientific basis for the evaluation of fisheries resources in Canada. As such, it addresses the issues of the day in the time frames required and the documents it contains are not intended as definitive statements on the subjects addressed but rather as progress reports on ongoing investigations.

Research documents are produced in the official language in which they are provided to the Secretariat.

This document is available on the Internet at: Ce document est disponible sur l'Internet à:

#### Abstract

Landings in the southwest Nova Scotia/Bay of Fundy spawning component in 2004 ( 78,000 t) were about 10,000 t lower than the previous year and near the average of the last decade. There continues to be signs of deterioration in the state of the stock. The 2004 catch was dominated by age 2 and 3 recruits and there was an absence of older fish. SSB on both Trinity Ledge and Seal Island spawning areas remain well below historical levels. The truncated catch at age and the rapid decline of individual year-classes indicates that total mortality may be considerably higher than estimated. There has also been little progress towards defined conservation objectives in recent years.

Acoustic surveys of spawning grounds indicate a relatively stable spawning stock biomass (SSB) in recent years. Combination of the absolute SSB estimate from acoustic surveys with fishery catch at age data in a virtual population analysis (VPA) implies a rapid and substantial biomass increase ( 5 -fold over the past 5 years) which has not been seen in the surveys and is inconsistent with the truncated age composition. A VPA calibrated with the trend in acoustic surveys suggests a relatively stable SSB of less than 200kt and a high fishing mortality ( F ). The pattern of residuals is acceptable, and this scenario matches observations recorded in the fishery (i.e. no large increase in biomass, high fishing mortality leading to truncated age structure).

Landings of 4,050 t from the 2004 offshore Scotian Shelf banks were below average since the fishery was reactivated in 1996. The 2004 fishery was dominated by catches of age 4 and 5 fish. In contrast, bottom trawl research survey catches from the past seven years have been the highest on record and herring were widely distributed on banks west of Sable Island.

Biomass estimates from acoustic surveys of the major coastal Nova Scotia spawning components were substantially lower for all surveyed areas in 2004 with large decreases for the Little Hope and Eastern Shore areas. There was no surveying from the Glace Bay area due to technical problems. Recorded landings showed a relatively large increase for the Eastern Shore area and decreases in the other main areas. The Bras d'Or lakes fishery was closed in 2004 and there was also no sampling.

There was an increase in landings in the traditional New Brunswick weir and shutoff juvenile herring fishery to 20,700 t from 9,000 t in 2003 but there is still a trend of decreasing landings over the past ten years.

## Résumé

En 2004, les débarquements de reproducteurs capturés dans le secteur sud-ouest de la Nouvelle-Écosse / baie de Fundy se sont chiffrés à 78000 t , soit environ 10000 t de moins que l'année précédente et l'équivalent approximatif de la moyenne des dix dernières années. L'état du stock continue de montrer des signes de détérioration. Les prises de 2004 comprenaient principalement des recrues d'age 2 et 3 . Les poissons âgés en étaient absents. La biomasse du stock reproducteur dans les frayères du récif de la Trinité et de l'île Seal demeure très inférieure à ses niveaux historiques. La répartition tronquée des prises selon l'âge et la baisse rapide de l'effectif des classes d'âge révèlent que la mortalité totale pourrait être considérablement plus élevée que prévu. Au cours des dernières années, les progrès vers les objectifs de conservation ont été insuffisants.

Les relevés acoustiques réalisés sur les frayères dénotent une stabilité relative de la biomasse génitrice, ces dernières années. Une analyse de population virtuelle (APV) fondée sur l'estimation de la biomasse génitrice absolue d'après les relevés acoustiques, combinée aux données des prises selon l'âge dans le cadre de la pêche laisse croire à une hausse rapide et importante de la biomasse (de l'ordre du quintuple sur les cinq dernières années), qui n'a pas été observée dans les relevés et qui n'est pas compatible avec la structure d'âge tronquée. Une APV étalonnée d'après la tendance observée dans les relevés acoustiques permet de penser que la biomasse génitrice est relativement stable, se chiffrant à moins de 200 kt , et que la mortalité par pêche $(F)$ est haute. Le profil résiduel est acceptable et ce scénario concorde avec les observations provenant de la pêche (notamment faible augmentation de la biomasse, forte mortalité par pêche entraînant une structure d'âge tronquée).

En 2004, les débarquements de géniteurs capturés sur les bancs du large de la plate-forme Néo-Écossaise se sont chiffrés à 4050 t , soit un niveau inférieur à la moyenne depuis la réouverture de la pêche en 1996. Les prises de 2004 comprenaient principalement des harengs d'âge 4 et 5 . Cependant, dans les relevés de recherche au chalut de fond des sept dernières années, les prises ont atteint des sommets records et les harengs étaient très largement répartis sur les bancs situés à l'ouest de l'île de Sable.

Les estimations de la biomasse effectuées à partir des résultats des relevés acoustiques des principaux groupes de reproducteurs sur les côtes de la Nouvelle-Écosse ont été substantiellement plus faibles pour chacune des zones ayant fait l'objet d'un relevé en 2004, des baisses importantes ayant été enregistrées dans les secteurs de Little Hope et d'Eastern Shore. Des problèmes techniques ont empêché la réalisation des relevés dans le secteur de Glace Bay. Les débarquements déclarés affichent une augmentation relativement grande pour le secteur d'Eastern Shore et des baisses dans les autres principales zones. La pêche dans les lacs Bras d'Or a été fermée en 2004 et il n’y a pas eu d'échantillonnage.

Au Nouveau-Brunswick, les débarquements de la pêche traditionnelle de harengs juvéniles à la fascine et à la senne de plage ont augmenté, se hissant à 20700 t , par rapport aux 9000 t de 2003, mais on constate toujours une tendance à la baisse pour les dix dernières années.

## 2004 Evaluation of 4VWX Herring

## Introduction

Atlantic herring is a pelagic species found on both sides of the North Atlantic. Herring spawn in discrete locations, to which they are presumed to home. Herring first mature and spawn at three or four years of age ( 23 to 28 cm or 9 to 11 in ), then begin a predictable annual pattern of spawning, overwintering, and summer feeding, which often involves considerable migration and mixing with members of other spawning groups. Most fishing takes place on dense summer feeding, overwintering, and spawning aggregations.

The 4VWX management unit contains a number of spawning areas, separated to various degrees in space and time. Spawning areas in close proximity with similar spawning times, and which share a larval distribution area, are considered part of the same complex. These undoubtedly have much closer affinity than spawning areas that are widely separated in space or time, and do not share a common larval distribution. Some spawning areas are large and offshore, whereas others are small and more localized, sometimes very near shore or in small embayments. The situation is complicated further as herring migrate long distances and mix outside of the spawning period both with members considered part of the same complex and with members of other spawning groups. For the purposes of evaluation and management, the 4VWX herring fisheries are divided into four components (Figure 1):

1. SW Nova Scotia/Bay of Fundy spawning component
2. Offshore Scotian Shelf banks spawning component
3. Coastal (South Shore, Eastern Shore and Cape Breton) Nova Scotia spawning component; and
4. SW New Brunswick migrant juveniles.

Each component has several spawning areas, and there is mixing of fish among spawning components. Industry and management have explored means of managing the complexity within each component (such as distributing fishing effort among spawning areas according to their relative size) and of taking appropriate account of interaction among components (such as fishing restrictions on some areas of mixing).

Fisheries in the 4VWX area in recent years have been dominated by purse seine, weir and gillnet, with relatively minor landings by shutoff, trap and midwater trawl (Table 1,2).

Since 1995, the herring stock assessment and related research has been enhanced by a number of projects undertaken with the assistance of the fishing industry. These include industry sampling of biological characteristics of the catch, acoustic surveys using industry vessels and tagging.

The Georges Bank spawning component (Figure 1) is not included in this evaluation except to document Canadian herring landings from that area (Table 1). This fishery is included in the Gulf of Maine stock complex and has been recently evaluated separately (DFO 2003a).

## 1) Objectives and Management

The 2003-2006 Scotia-Fundy Herring Integrated Fisheries Management Plan (DFO 2003b) sets out principles, conditions, and management measures for the 4VWX herring fisheries. The main principle stated in the plan is "the conservation of the herring resource and the preservation of all of its spawning components".

Three conservation objectives developed and reviewed by Sinclair (1997) appear in the plan:

1) To maintain the reproductive capacity of herring in each management unit through:

- persistence of all spawning components in the management unit;
- maintenance of biomass of each spawning component above a minimum threshold;
- maintenance of a broad age composition for each spawning component; and
- maintenance of a long spawning period for each spawning component.

2) To prevent growth overfishing:

- continue to strive for fishing mortality at or below F0.1

3) To maintain ecosystem integrity/ ecological relationships ("ecosystem balance").

- maintain spatial and temporal diversity of spawning
- maintain herring biomass at moderate to high levels

There is evidence that most of these objectives are not being met despite the efforts that have been made in recent years. There is also a need to better define these objectives in terms of minimum thresholds and to explicitly list the spawning components in terms of spatial and temporal expectations.

An "in-season" management process, first implemented in the southwest Nova Scotia fishery during 1995, continued to be used widely within the 4VWX management area (DFO 1997, Stephenson et al. 1996, 1999a). The approach encouraged surveying using the commercial fleet under scientific direction prior to fishing ("survey, assess, then fish" protocol) to ensure that effort was distributed appropriately among various components of the stock (particularly among spawning components) according to the relative size and current state of each component. The use of this approach in recent years has improved data collection
and enabled modifications to management decisions to be made with the involvement of participants and on the basis of up-to-date information.

Collaborative research efforts with the fishing industry have been important in recent years. A major portion of the herring industry (including the purse seine sector and major processors) forms the Herring Science Council (HSC), and some members of the fixed gear sector have undertaken a separate Joint Project Agreement with DFO to undertake collaborative scientific projects. The herring industry has continued to provide biological sampling and samples while the purse seine and gillnet sectors undertook key acoustic surveys. Under the auspices of the HSC a dedicated field biologist also takes part in initiatives such as tagging, summary of fleet activities (Appendix A), and analysis of acoustic records from fishing trips.

## 2) SW Nova Scotia/Bay of Fundy Spawning Component

### 2.1 The Fishery

Herring fishing locations, NAFO unit areas used for catch and sample aggregation, and fishing areas defined by groupings of 10 mile squares (i.e. 10 minute squares of latitude and longitude) are shown in Figures 2 to 5.

The 2004 catch limit for this component was 83,000 t, a decrease of 10,000 t from the previous year (Table 3, Figure 6). Eighty percent of the catch limit was initially allocated to the mobile gear sector and $20 \%$ to the fixed gear sector, as has been done historically. Transfer of quota to the mobile fleet occurred late in the season.

Total landings from this component in 2004 (78,030t) were 11,300t lower than the previous year, and close to the average for the last decade (Table 3). Decreased landings by the purse seine sector accounted for most the decline, with minimal landings by the gillnet sector (225t) and the Nova Scotia weirs (3,130t) showing an increase from only 900t in 2003.

The temporal and spatial distribution of the purse seine fishery was similar to that of the recent decade except for the Scots Bay area (Table 4-5). The largest purse seine fisheries occurred on the German Bank and Scots Bay spawning grounds, and on summer feeding fish off Long Island, N.S. and around Grand Manan (Figure 7). There was a substantial increase in the 2004 landings for Scots Bay to 24,900t, the highest on record for this area. The next most important area in terms of overall landings, German Bank, experienced a sharp decline in the landings from about 20,000t to 14,000t.

During the 1970's and 1980's, a large fishery took place on over-wintering aggregations in Chedabucto Bay. In recent years however, there has been no fishing effort in this area as traditional vessels have been successfully fishing
elsewhere. In some years there has been a small fishery on over-wintering herring in January off Halifax Harbour (Chebucto Head), but the majority of the fall and winter herring landings for the past several years have come from the New Brunswick side of the Bay of Fundy (Figure 8-10) and take place from Oct. to Feb.

The summer purse seine fishery took place in the same areas as in previous years (Figure 9). A large part of this fishery was directed on the major spawning grounds in Scots Bay and on German Bank (Figure 11, 12) where recent catches are primarily within the pre-defined acoustic survey areas (Melvin and Power 1999). The Trinity Ledge spawning ground, which is still recovering, is closed to purse seine gear from Aug. 15 to Sept. 15 but there were acoustic surveys followed by some catch (250t) by drift gillnet gear (Figure 13). There was no drift gillnet fishery in the Spectacle Buoy area in 2004. This small fishery of $<500$ t has occurred only sporadically in recent years during the month of June. Additional catches by drift gillnet gear occurred in Sept. to Oct. in the Little Hope/Port Mouton spawning grounds. There were also set gillnet catches along the Eastern Shore to the east of Halifax and near Glace Bay in Cape Breton (Figure 14).

Catches in the Nova Scotia weirs of 3,130 t were substantially higher than the recent lows of 2000 and 2003 (Table 3; Figure 15). The annual variation has been attributed to problems in availability of fish to this fixed stationary gear as there continues to be substantial catches by purse seine in the nearby Long Island area on the Bay of Fundy side of Digby Neck. The seasonal timing of the Nova Scotia weir landings has shifted in the last 3 years with a higher proportion of landings now as late as Aug. and Sept. as compared with the traditional early fishery seen in May and June previously (Table 6). Catches in recent years for the Nova Scotia weirs have been highly variable and not as consistent in their amount or timing as in the previous decade. There has been a decline in the total number of herring weirs but the catch per weir (t) for the Nova Scotia weir fishery has remained high (Table 7).

## Catch and Effort

Catch and effort which were examined for gillnet data in the previous assessment showed little trend and are considered unrepresentative due to the very small amount of effort (Power et al., 2004). This trend in reduced catch and effort continued in the 2004 fishing season and so this data was not reexamined.

Purse seine landings make up most of the overall catch and are allocated $80 \%$ of the TAC in the SW Nova Scotia/Bay of Fundy component under the current management plan. The purse seine catch has fluctuated between 60 and 100 thousand tones since 1989 with a steady increase in recent years reflecting increases in the TAC (Table 8, Figure 16). The overall number of boats fishing and days fished has been dropping since 1990 due to some fleet rationalizations. This has resulted in increases in catch per boat and catch per day in recent years.

### 2.2 Resource Status

## Acoustic Surveys

Automated acoustic recording systems deployed on commercial fishing vessels were used to document the distribution and abundance of Atlantic herring in NAFO Division 4VWX through industry vessel surveys and fishing excursions (Melvin and Power 1999). Regularly scheduled surveys, at approximately 2-week intervals, were conducted on the main spawning components and the spawning stock biomass for each component was estimated by summing these results (Power et al. 2005).

In 2004, four surveys were conducted in Scots Bay, two on Trinity Ledge and three on German Bank following established protocol and providing adequate coverage of these spawning areas consistent with previous years. Additional data from fishing nights in Scots Bay and German Bank were also examined and used as appropriate.

Biomass estimates for Scots Bay, Trinity Ledge and German Bank calculated as in previous assessments were approximately 106,600t, 6,500t, and 367,600t for a total surveyed SSB of 481,700t in the traditional survey areas, a slight decrease from the previous year (Table 9). The SSB for Scots Bay was down by about 25\% and is of concern, especially in light of the increased effort and landings for this area. The spawning period in Scots Bay based on catches and samples was the longest recorded. German Bank had a slight increase in SSB despite only three structured surveys over a limited time period. The duration of spawning on German Bank was contracted and no structured surveys occurred on German Bank in October.

The documented amount of spawning fish on Trinity Ledge was lower than in the past three years but survey coverage was limited. There were no surveys and no reports of spawning herring on Lurcher or Seal Island spawning grounds.

## Spawning ground turnover rates

The current acoustic survey method on spawning grounds is dependent on periodic turnover of spawning fish on the grounds. Acoustic surveys are required to be separated by at least 10 to 14 days to allow for turnover and to prevent double counting (Power et al. 2002). This aspect of the assessment method was the subject of investigation in 2001 and of intensive sampling for maturity stage in since the 2002 fishing seasons. The results are summarized by Melvin et al. (2003, 2004, Power et al. 2005) and were used to assist in the evaluation of turnover timing and the inclusion or exclusion of specific acoustic surveys.

## Exploitation Rates on Spawning Grounds

The acoustic surveys were explored in and attempt to estimate partial exploitation rates for spatially and temporally different spawning groups. This is useful information for assessing the impact of fishing on individual spawning units as well as for the overall stock component (Table 10). For this analysis only the three major spawning components (i.e. Scots Bay, German Bank, Trinity Ledge) that have received consistent survey effort were included. Since there are also questions about comparability of acoustic surveys, in terms of the area of survey coverage among years, only data since 1997 are shown and only data since 1999 are included in the overall averages (Table 10-A1). Catches throughout the year from the spawning grounds were assumed to be site specific (Table 10-C1), while catches from all other areas were considered non-spawning and were allocated based on the relative spawning ground SSB proportions (Table 10-A2, C2). In addition the SSB for Seal Island and Spectacle Buoy were allocated to the German Bank spawning area. The exploitation rates were calculated for both the actual catch on the spawning grounds and the overall adjusted catch as Catch / SSB (Table 10-P1, P2).

Calculation of exploitation rates by component since 1999 showed that the larger grounds (German Bank and Scots Bay) have an overall exploitation of 14 to 31\% while Trinity Ledge had higher levels (up to $146 \%$ ) which may be a problem of catch allocation as well as inconsistent survey effort over the period. The overall exploitation rate for the $4 W X$ stock ranged between 14 and $18 \%$, which are at or slightly below the target of F0.1 $=0.22$ (exploitation of 18\%). These rates are dependant on the assumption that the acoustic survey SSB is correct and that catches have been properly allocated.

## Fleet Activity

A summary of daily fishery information compiled by the Herring Science Council and DFO confirmed that the fishery on this component was largely as expected in location and timing, and that there were substantial amounts of herring in some areas other than spawning grounds (Appendix A). In recent years there has been an increase in market for juvenile herring for both lobster bait and to offset a shortfall in weir landings which has been a traditional source of juveniles.

## Tagging

From 1998 to 2002, the Pelagics Research Council/Herring Science Council, in partnership with Fisheries and Oceans Canada, tagged herring on spawning grounds and on the major Nova Scotia overwintering grounds. Although this project has concluded, tags continue to be returned. The information on tags returned from this study has been summarized by Waters and Clark (2005).

## Sampling and Catch at Age

Comprehensive biological sampling continued with substantial involvement of the fishing industry. A total of 1,485 samples comprising 172,700 fish were measured for length while 5,800 fish were sampled for age. The distribution of samples by gear and month is presented in Table 11. The sources of samples are shown in Table 12 with the bulk of samples coming from the processing industry, as has been the case since 1996. Additional samples were collected by: DFO personnel, observers deployed on purse seine vessels and from DFO research surveys. Sampling from the commercial fishery was well matched to the spatial and temporal distribution of the fishery. Additional sampling from research vessel surveys during the spring and summer resulted in widespread geographic coverage as in the past (Figure 17).

Age reading consistency tests are done in order to evaluate the accuracy and precision of age reading. In 2004 a sub-sample of 200 otoliths were selected from the 2004 collection for the purpose of a within reader test. This collection lacked the full range of ages and 20 were added to include 1 year old fish. There was good representation of the months, areas and gear types sampled during the year. The first ten otoliths were selected from each sample selected for this test. Otoliths were read and compared with previous age determinations. The results for read1 show an agreement of $88 \%$ with aged fish but did not include 1 y old fish. There was $93 \%$ agreement with aged fish for the second age reading which included 1 y old fish. The coefficient of variation was $1.9 \%$ (Table 13, Figure 18).

Consistent with previous assessments, the catch at age was constructed using the MFD 'Catch at Age' application (version 9beta) which is a Marine Fish Division windows based program for computing catch at age statistics as part of the stock assessment process. Data files used by 'Catch at Age' were created with the 'CATCHFRM' application that was used to select fish sample data from the Pelagic Samples Database. These data included a $2 \%$ adjustment for the shrinkage due to freezing on the length measurements for frozen samples (Hunt et al. 1986). The length-weight relationships, which are also required as input to the 'Catch at Age' application, were calculated using an Oracle SQL*Plus script. The catch at age statistics were then calculated from length frequency and age-length key samples expanded to total catch using appropriate monthly length-weight relationships. The data were grouped or combined and then age-length keys were applied to length frequencies to produce catch at age statistics by NAFO unit area, gear-type and month.

## Age Composition of the Catch

Under $\mathrm{F}_{0.1}$ fishing and constant average recruitment, the age composition of the population caught in the fishery would be expected to be similar to that shown in Figure 19. There would be peak abundance at age 4, substantial fish surviving older than age 6 and a buildup of fish at ages 11+. This expected or ideal age
structure has been used in recent assessments for comparison with the actual catch at age which has been characterized by a predominance of younger ages 23 and few fish older than six years old (Stephenson et al. 1999b, 2001; Power et al. 2002, 2003,2004).

In the 2004 fishery, the 2001 year-class (at age 3) dominated the catch at age by weight (about 36\% of the weight of herring landed). The 2001 and 2002 yearclasses were similar by number (35-36\%) in the catch (Table 14, Figure 20). The pattern of dominance by age 2 and 3 fish was seen across all gear components except gillnet where age 5 fish were most prominent by number and weight, reflecting the selectivity of the gear (Table 14, Figure 21). The catch at age was also broken down by unit area, month and fishing ground for the purse seine sector which made up the majority of the overall catch (Table 15,16,17; Figure 22-24). Once again, age 2 and 3 predominated in most areas and months, except for German Bank (area 4Xq) off southwest Nova Scotia where age 4 was the highest by number and weight.

The historical time series of catch at age was extended to include the current fishing year and is shown as total number caught as well as percent by age (Table 18-19). The series shows very few fish older than age 7 in recent years and has been dominated by ages 2 through 4 since 1998 (Figure 25). The series is primarily made up of fish age 6 and younger but older ages were a feature when strong year-classes (i.e. 1976 and 1983) were progressing through the fishery (Figure 26).

Age composition in the fishery deteriorated further in 2004, and remains a concern. The proportion of age $4+$, $5+$ and $7+$ were derived from the catch at age in numbers to determine trends in the older fraction of the catch (Figure 27). Age 7+ has shown a declining trend since 1990 corresponding to the demise of the 1983 year-class, which was the last very strong year-class in this component. Age 5+ is more variable but has also exhibited a declining trend in recent years. Age 4+ has declined since 1996 except for 2002 with recruitment of the strong 1998 yearclass. There are few old fish (few age 7+; only $10 \%$ age $5+$ by number) and the proportion of age 4+ in the catch has declined to about 20\%. The rapid decline of year-classes (including the strong 1998 year-class) implies a high total mortality.

The trend toward catches at younger ages results in reduced yield and is reflected as an increase in the average number per ton from the overall catch at age (Figure 28). This indicator has doubled from about 6000 fish per ton (average fish of 167 g ) in the 1980's and 1990's to about 12,000 fish per ton (average fish of 83g) in the current year. These levels of removals per ton have not been observed since 1975, which was just prior to the closure of the meal fishery, the implementation of individual boat quotas and the conversion to a food fishery by the industry (lles 1993). There is cause for concern for a recruitment fishery on younger ages when there is a lack of knowledge on the size of these incoming year-classes.

## Weight at Age

The average weights at age showed little change for all ages in the most recent years (Table 20 and Figure 29), and were within the range of data observed historically (Power and Iles 2001). The most recent 5 year and 10 year average weights at age are consistently lighter than the overall series average (Figure 30) and reflect a general decline in weight at age that occurred for all ages in the mid 1980's.

## VPA Analysis

Acoustic survey results have been used in previous assessments as absolute estimates of SSB and approximately 500kt have been recorded in each of the past six years. However, there are several indicators that SSB is not this high. An SSB of about 500kt would have been expected to result in substantial growth of the population since the late 1990s, improved age composition and low fishing mortality, given reasonable recruitment and the landings of recent years (less than 80kt in 2004). Such growth in the population and expansion of age composition has not been observed in the surveys or fishery. In recent assessments, it has been noted that the declining proportion of older fish in the population suggested that the total mortality on this stock was much higher than that implied by the ratio of catches to acoustic SSB.

Age specific indices of abundance were constructed from the acoustic survey data using samples appropriate for each survey conducted by area and year for 1999 to 2004 and applying the biomass estimates that were determined (Table 11, Figure 31-32). These indices were then used as the primary input for tuning or calibration of the VPA. The catch at age from the fishery is also used to reconstruct the population history using virtual population analysis (VPA) (Table 18, Figure 26). Population reconstruction from the catch at age requires some assumptions to be made about conditions in the terminal year. One assumption is about the exploitation pattern at age (partial recruitment); examination of this pattern since 1990 suggests that an exploitation pattern at age of $0.2,0.4,0.7$ and 0.9 for ages 2-5 and 1.0 for age 6 and older is a reasonable approximation (Figure 33). Other assumptions for the population reconstruction follow traditional approaches, i.e. $\mathrm{M}=0.2$ and $\mathrm{F}_{10}=$ population weighted average for ages 6-9.

The remaining specification required to conduct a population reconstruction is the magnitude of the population abundance at age 7 in 2004; two illustrative reconstructions were initially completed.
a) Illustrative VPA absolute: the population abundance at age 7 was chosen such that the spawning biomass in the terminal year approximated the absolute magnitude of the acoustic survey biomass index, about 500,000 mt.
b) Illustrative VPA flat trend: the population abundance at age 7 was chosen such that the trend in spawning biomass was flat, corresponding to the flat trend displayed by the acoustic survey biomass trend.

These results were then used as a starting point for a calibrated or tuned VPA using the acoustic index as either an absolute index or as a proportional index. The acoustic survey estimates may be used as absolute estimates of spawning biomass or for the relative trends in biomass. In the initial analysis, the acoustic index in absolute terms was related to population numbers. The results were very similar to the illustrative absolute with population numbers and fishing mortality (Table 22-23, Figure 34-35) showing an SSB of about 600kt. Combination of the absolute SSB estimate from acoustic surveys with fishery catch at age data in a virtual population analysis (VPA) implies a rapid and substantial biomass increase ( 5 -fold over the past 5 years) which has not been seen in the surveys and is inconsistent with the truncated age composition. SSB levels of over 400kt have only been seen a few times over the 40 year history of this fishery. It is therefore apparent that the absolute SSB from acoustic surveys result in an overestimate. Potential reasons for an overestimate of SSB include uncertainty regarding the residence time on spawning grounds, as well as the possibility of double counting and inappropriate target strength coefficient for converting backscatter signal to biomass. The diagnostics for this run shows an unacceptable pattern of residuals with large negative residuals for ages 2 and 3 for all years and large positive residuals for ages 4 to 9 for all years (Figure 36-37).

Use of the acoustic survey data as a relative or proportional index of abundance resulted in a more consistent analysis. Acoustic surveys of spawning grounds indicate a relatively stable spawning stock biomass (SSB) in recent years. A VPA was calibrated with the trend in age structured acoustic survey results, using fishery catch statistics and sampling for size and age composition of the catch for the years 1965-2004 as basic input. These VPA results suggest a relatively stable SSB of less than 200kt and a high $F$ (much greater than FO .1 ) in recent years. This scenario matches observations from the survey (relatively constant SSB) and the fishery (including little increase in biomass and a reduced age composition). The results were very similar to the Illustrative flat trend with population numbers and fishing mortality (Table 24-25, Figure 38-39) showing an SSB of less than 200kt and high F . The pattern of residuals is acceptable with a mixture of moderate size positive and negative residuals (Figure 40-41). This scenario matches more closely what has been recorded in the fishery with little increase in biomass and high fishing mortality leading to reduced age composition.

Diagnostics for the VPA as proportional include results for the parameters being estimated by the model (Table 26). The population abundance at age 7 in 2005 was estimated as 4,874 million with a moderately high standard error of $47 \%$ and a low bias of $9 \%$. The other parameters estimated were the Q's or catchabilities for ages 2 to 9 which also had moderate SE's of $36-40 \%$ and low bias of $6-8 \%$. The trend of increasing Q's at age and the lack of the typical dome or flat-top trend at
older ages is unusual and may be due to the short time series and lack of older fish in the population (Figure 42).

Calculations of total mortality ( $\mathrm{Z}=$ Fishing mortality + Natural mortality) were calculated using the acoustic and fishery catch at age data. Z calculations are typically quite variable but can often be used to detect broad patterns and for confirmation of VPA results. The $Z$ values were calculated using ages 4 to 8 compared with ages 5 to 9 in the following year.

The acoustic age composition is assumed to be representative of the overall spawning biomass. The results for 2000 to 2004 have high values of $Z$ between 0.5 and 1.5 with one negative value (Figure 43). There is no apparent trend as the series is very short; however these values appear consistent with the higher F's estimated from the proportional VPA.

Total mortality may also be derived from the fishery catch at age but requires the assumption that effort has been stable over the period being analyzed. This assumption may be valid for the recent decade with catches in the range of 60 to 90kt (Figure 16). Similar to the acoustic series, the $Z$ values are high and variable but with no trend in recent years (Figure 44).

Projection results and risk analysis are provided in terms of the consequences of various catch quotas (yield) (Table 27, Figure 45). To have a low to neutral risk of exceeding $\mathrm{F}=0.2$ requires a catch of about 25,000 t or less. Because of the incoming recruitment, catches as high as 40,000 t still have a neutral to high chance for $40 \%$ biomass increase. These results are also shown in terms of exploitation rate and expected biomass change for various yields (Figure 46).

Fishery catches are considered reasonably reliable and it is not thought that large amounts of unreported catch have occurred in recent years. Age interpretation appears to track strong and weak year-classes historically and there is consistency of age interpretation between and within readers across years. Acceptance of the absolute acoustic survey biomass implies a rapid and substantial biomass increase, five fold over the past 5 years, with an associated reduction in fishing mortality rate from over 1.0 to 0.3 (Figure 35)

There is strong support for the interpretation of stock status that the trend in biomass has been flat over recent years and the total biomass is less than half of the acoustic survey estimate (Figure 38). It should be emphasized that the acoustic index only provides information on about $50 \%$ of the total biomass with younger ages estimated with average partial recruitment. In addition, biomass levels of over 400kt have only been seen a few times over the 40 year history of this fishery. About half of the catch biomass in recent years was comprised of ages 2 and 3 and there is no information about the 2003 year-class (age 2 in 2005) and the estimate of the 2002 year-class (age 3 in 2005) is very dependent on the assumed partial recruitment of 0.2.

### 2.3 Sources of Uncertainty

The evaluation of stock status in this area relies in large part on the spawning stock biomass estimates derived from industry acoustic surveys. There is considerable variability around individual acoustic survey estimates (standard errors are in the range of 10-60\%) although studies of individual weir catches indicate that acoustic biomass estimates are within $15 \%$ of the amount of fish harvested. Uncertainty may also arise from assumptions concerning the residence time of herring on spawning grounds, target strength estimates and the temporal coverage of surveys in relation to the extent of spawning.

### 2.4 Ecosystem Considerations

Herring is prominent in the diet of many fish, seabirds and marine mammals, and should be managed with these interactions in mind. At present, use of a natural mortality rate of 0.2 and maintenance of SSB at moderate to high levels are assumed to account for these interactions.

Recent management initiatives to protect spawning components are intended to maintain the spatial and temporal diversity of herring spawning. Increased fishing on juveniles, which are of mixed or unknown stock affinity, is inconsistent with this objective.

### 2.5 Outlook

Recent assessments of the SWNS/BOF spawning component suggested that fishing mortality should remain below F0.1 (about $20 \%$ exploitation rate) for a number of years in order to rebuild spawning stock biomass in all spawning areas and to expand the age composition so as to meet the explicit biological objectives of management.

The 2004 fishery was 11,000t less than in the previous year. Although acoustic surveys continue to show an SSB of approximately 500,000t, there continues to be deterioration in the state of the stock and some of the conservation objectives specified for this fishery are not being met. There is an absence of older fish in the population and increased targeting of juveniles. While there is spawning on Trinity Ledge and a small amount of spawning has been observed in recent years near Seal Island, the SSB on both Trinity Ledge and Seal Island spawning areas remain well below historical levels.

The rapid decline in year-classes (failure to reach older ages), even in the strong recent 1998 year-class, indicates high total mortality. It seems that the current catch is substantially higher than what would be consistent with a moderate F. Although these high exploitation rates have not resulted in a reduction of surveyed spawning biomass (presumably due to reasonable recruitment), the rebuilding that these recruits may have represented has been lost.

Recent catches have been mostly consistent with the survey, assess, fish protocol of less than $20 \%$ of surveyed biomass. However the catch at age indicates that total mortality may be considerably higher. The increased trend to catch juveniles could compromise SSB, expansion of age composition and reoccupation of spawning grounds.

### 2.6 Management Considerations

An evaluation of progress against biological objectives in the management plan (DFO 2003b) indicate that most objectives are not being met (Table 28). In particular there are limited signs of recovery for the Trinity Ledge and Seal Island spawning components and there are few fish older than age 7 in the catch indicating high total mortality and the rapid decline of year classes. Also there is apparent high total mortality and targeting on 2 year olds. Although there has been limited fishing on Trinity Ledge in recent years, the current high exploitation rate (including the catch of these fish outside of the spawning area) appears to be impairing recovery. Some objectives appear to have been met, in particular on spawning components like German Bank and Scots Bay, where the SSB is apparently at stable levels in recent years.

The in-season management approach, which spreads the effort in the fishery spatially and temporally among spawning components, is seen as beneficial in achieving the conservation objectives. The "survey, assess, then fish" protocol is effective in spreading the catch appropriately among spawning components in proportion to their relative size and is considered an important safeguard.

Acoustic surveys have become critical to stock status evaluation. Surveys conducted in 2004 conformed to the proposed survey design. It is important that there be continued attention to coverage and survey design in order to assure year-to-year consistency in all spawning areas.

This assessment has confirmed a further deterioration in the state of the resource noted in the previous assessment. However, the change in use of acoustics as a relative rather than absolute abundance index has resulted in large change in the perception of the resource. As indicated earlier, the apparent absolute SSB is inconsistent with most other information. Possible reasons for the overestimate of SSB by the acoustic surveys have been proposed but more work is required.

## 3) Offshore Scotian Shelf Banks Spawning Component

### 3.1 The Fishery

A foreign fishery during 1963-1973 is estimated to have removed as much as 60,000t per year from the offshore Scotian Shelf banks (Stephenson et al. 1987). Few herring were caught after the extension of jurisdiction in 1977 until 1996, when a fishery was initiated by the 4WX purse seine fleet and 11,700t was taken (Table 3).

Since 1996 a fishery has taken place on feeding aggregations on the offshore banks primarily in May and June with catches ranging from 2,000 to 20,000t (Table 3). The variability in catch levels was often due to problems of fish being too deep, weather and market conditions rather than in the abundance of herring in these areas.

In 2004, fishing took place in June, in the vicinity of the Patch, the Bullpen and MacKenzie Spot. (Table 1, Figure 47). Landings of 4,000t from the 2004 fishery on the Scotian Shelf Banks were below the nine year average (approx. 9,000t) (Figure 48).

In 2004, herring continued to be caught as by-catch in the domestic bottom trawl fishery on the Scotian Shelf edge and slope with 110t reported (Table 1). There was no midwater trawl activity on the offshore Scotian Shelf banks in 2004.

The 1999 to 2001 year-classes (ages 3 to 5) made up most of the age composition of the Scotian Shelf fishery with age 5 dominating in both number and weight (Table 29, Figure 49).

### 3.2 Research and Industry Surveys

## Industry Surveys

Fleet activity/catch in the spring/early summer fishery on the offshore banks of the Scotian Shelf continued to decrease in 2004. Acoustic recorders were activated on a few occasions but insufficient quantities of fish were observed to warrant analysis. Consequently there were no industry surveys of the area in 2004 and no acoustic biomass estimates were available from the Scotian Shelf (Power et al. 2005).

## July Bottom Trawl Survey

Previous results from the summer bottom trawl survey showed few herring on the Scotian Shelf during the 1970's, increasing amounts during the 1980's and a relatively widespread distribution in recent years (Harris and Stephenson 1999, Power et al. 2004, Stephenson et al. 2001).

Offshore herring catches from this survey in 2004 were the highest in the 35-year time series, with an average of over 350 fish per standard tow for strata 55 through 78 (Table 30, Figure 50). Survey catches of the past seven consecutive years have been the highest on record. It should be noted, however, that in 2004 a replacement survey vessel (Teleost) was used while following standard survey methods. As of yet there have been no inter-vessel conversion factors established for differences in fishing efficiency by species and results for 2004 need to be used with caution.

Increasing trends are also similar for the combined strata from each of the areas 4W and 4X (Table 30, Figure 51). The strata areas used for selection of trawling stations in this bottom trawl survey series are shown in Figure 52. Herring were again widely distributed on banks west of Sable Island (Figure 53) and were comparable to average catches from the last ten years (Figure 54). The overall size distribution for catches from all strata in $4 W X$ shows that the bottom trawl catches a complete spectrum of herring from 5 cm up to 40 cm (Figure 55); however there are few fish larger than 35 cm in recent years.

The survey data for areas $4 W X$ combined were also analysed by age to produce stratified mean numbers per tow over the series (Table 31, Figure 56). There was a lack of consistency with the large year-classes observed in the fishery and a lack of tracking of these year-classes from year to year. There have been two major changes in the catch rates by bottom trawl over the series; the first is with to the introduction of the Alfred Needler in 1987 and a second large increase since 1994. There is also the issue of using uncalibrated Teleost catches for 2004. The plot by age and year shows a lack of older ages in the catch over the past decade but does not appear to track strong year classes consistently (Figure 57).

The proportion of age 4+ and 7+ were derived from the bottom trawl catch at age to determine trends in the older fraction of the catch (Figure 58). Similar to the trend seen in the fishery catch at age the 7+ fraction has shown a declining trend since 1990 corresponding to the demise of the 1983 year-class, which was the last very strong year-class in this component. Age 4+ is highly variable and does not follow the declining trend observed in the catch.

## Fall Herring Research Survey

There has been no fall herring research survey on the Scotian Shelf since 2002 when the research vessel Alfred Needler was used.

### 3.3 Outlook and Management Considerations

The summer bottom trawl research survey demonstrates that there is a considerable abundance of herring widely spread over the offshore banks of the Scotian Shelf. Information from previous assessments indicated the presence of at
least some autumn spawning on Western Bank in recent years. There is very little new information to add and no reason to change the previous outlook:

- Recorded landings in the foreign fisheries of 13,000t to 60,000t between 1969 and 1973 did not appear to be sustainable.
- The initial catch allocation for 2004 should not exceed the 12,000 t reference value used in the recent fishing plans.

There continues to be insufficient documentation of stock size, distribution and spawning behaviour for this component. Industry, DFO Science and Management are encouraged to continue to work together to improve the biological basis for management. There continues to be the need for industry surveys to estimate abundance.

## 4) Coastal (South Shore, Eastern Shore and Cape Breton) Nova Scotia Spawning Component

### 4.1 The Fishery and Resource Status

In addition to traditional coastal fixed gear fisheries for subsistence and personal bait, there has been an increase in the number of active gillnet licenses in recent years aimed at spawning herring for the roe market (Clark et al. 1999). This was the ninth year for a fishery on spawning fish off Halifax/Eastern Shore and the eighth year of gillnet roe fisheries off Little Hope/Port Mouton and Glace Bay.

The recorded landings $(7,000 t)$ in 2004 in the four major gillnet fisheries along the coast of Nova Scotia were higher for the Eastern Shore, but lower for Little Hope/Port Mouton and Glace Bay. The Bras d'Or Lakes fishery remained closed (Table 32).

Biomass estimates from surveys of the major coastal Nova Scotia spawning components were much lower in 2004 with a large decrease in the estimated SSB for both the Little Hope (4Xo) and Eastern Shore (4Wk) areas (Table 33) (Power et al. 2005). In both areas, the reduction was partly attributed to difficulties of surveying in adverse weather conditions in 2004. There was no biomass estimate for the Glace Bay ( 4 Vn ) area because of equipment problems and there was no acoustic survey effort in the Bras d'Or Lakes. Although the results of acoustic surveys are reported here as absolute abundance, the discussion in the SW Nova Scotia/Bay of Fundy component suggests that they may overestimate SSB.

Management of these spawning components using "survey, assess, then fish ( $<10 \%$ )" protocol is considered useful when the components are considered to be healthy and of sufficient size. The history of the application of this protocol has had some mixed success due to some occasional problems in executing surveys (Table 33).

Exploitation rates for the coastal areas with acoustic survey estimates have been calculated as the proportion of landings against estimated SSB (Table 34).

## Little Hope

The fishery in the Port Mouton/Little Hope area occurred primarily in October with a total of 1,270 t of herring landed (Figure 59). Length samples were taken from October 2-4 with a mean size of 28 to 30 cm (Figure 60). Only one sample of spawning fish was available from Oct. 2 most in spawning condition (Figure 61). Sampling indicated that the catch was composed primarily of the 1999 year-class at age 5 (Table 35, Figure 62).

A total of two acoustic surveys took place on the spawning ground on Oct. 2 and Oct. 13, 2004 (Power et al. 2005). The overall acoustic estimate for this area was 15,600t (15\% SE).

## East of Halifax (4W Eastern Shore)

The roe fishery for the Eastern Shore area in September and October landed 4,200 t an increase of about 1,500t from 2003 (Figure 63). Sampling was limited to the two survey nights that took place and indicated that the catch was composed of large spawning fish mainly of the 1997-1999 year-classes (age 5-7) (Figure 6466 , Table 35).

Acoustic surveys undertaken by the Eastern Shore Fishermen's Protective Association in September and October 2004 estimated an SSB of 18,200t (9\% SE), substantially lower (decrease of $58,300 \mathrm{t}$ ) than recent years (Table 33) (Power et al. 2005).

## Glace Bay

The fishery off Glace Bay, Cape Breton took place in October with total landings of $1,500 \mathrm{t}$, which was a slight decrease from the previous year (Table 32, Figure 67). Length samples indicated large herring, mostly over 30 cm in total length (Figure 68), while maturity samples taken in September were primarily of spawning fish. Fish aged 7 (1997 year-class) dominated the catch (Figure 69, Table 35).

As a result of equipment problems, no acoustic survey information was available for 2004. This problem will be rectified in 2005.

## Bras d'Or Lakes

The fishery was closed in 2004. No sampling or acoustic surveys were undertaken in the Bras d'Or lakes to document the size distribution or abundance of herring.

### 4.2 Outlook and Management Considerations

There is no overall quota for the coastal Nova Scotia spawning component and apart from the areas mentioned above; the size and historical performance of various spawning groups are poorly documented. In addition to traditional fisheries for bait and personal use, there have been directed roe fisheries on the spawning grounds in recent years. As the inshore roe fisheries off Glace Bay, East of Halifax and Little Hope have developed, participants have contributed to sampling and surveying and the fisheries have attempted to follow the 'survey, assess, fish' protocol.

Management approaches and recent research efforts have improved knowledge in these three areas (Little Hope/Port Mouton, Halifax/Eastern Shore and Glace Bay), but there has been no increase in knowledge in adjacent areas. Individual spawning groups within this component are considered vulnerable to fishing because of their relatively small size and proximity to shore. As in the past five years, it is recommended that no coastal spawning areas should experience a large effort increase until much more information is available on the state of that spawning group, and there should be no new fisheries developed when there is uncertainty regarding stock composition and degree of mixing.

It has been noted since 1997 that the status of herring in the Bras d'Or Lakes is cause for concern. Spawning is still absent from some traditional areas and the observed biomass of spring spawners is very low. It is therefore appropriate to reiterate from a biological perspective, that no fishing take place on this spawning component.

## 5) SW New Brunswick Migrant Juveniles

The southwest New Brunswick weir and shutoff fisheries have relied, for over a century, on the aggregation of large numbers of juvenile herring (ages 1-3) near shore at the mouth of the Bay of Fundy. These fish have been considered to be a mixture of juveniles, dominated by those originating from NAFO Subarea 5 spawning components, and have therefore been excluded from the $4 W X$ quota.

The number and distribution of active weirs have decreased over the past decade, due in part to the conversion of sites to aquaculture, as well as the reduction in landings over the past decade in the Passamaquoddy Bay area (Table 3, 7). In the previous season (2003) there was a large drop in landings in the traditional New Brunswick weir and shutoff fishery to 9,000 t - the lowest since 1983 - and there was concern expressed for this fishery. In 2004 weir landings increased to 20,600t (Table 1, Figure 70), the highest since 1994, but there is still a trend of decreasing landings in this fishery in the past decade (Table 3, Figure 71).

The 2004 catch was dominated by the 2002 year-class (age 2) in number and the 2001 year-class (age 3) by weight. Mature herring (ages 4+) taken in this fishery are considered to be of 4WX origin (Table 36, Figure 72).

In 2002 the Fundy Weir Fishermen Association, Inc., in partnership with the New Brunswick Department of Agriculture, Fisheries and Aquaculture, the Grand Manan Fishermen's Association, Connors Brothers Ltd. and Fisheries and Oceans, Canada, initiated a tagging program, to be conducted over a three year period. The purpose of this project is to investigate the seasonal movements and migration of herring in the Bay of Fundy with the long-term goal of providing information on stock structure. Since the start of this project a total of 77,957 herring have been tagged and 2,741 tags have been recovered. The latest results to date are summarized by Waters and Clark (2005).

Preliminary results from tagging studies conducted on weir fish since August 2002 have indicated a link between the fish caught in the weir fishery and those caught in the fall and winter purse seine fishery off Grand Manan. The juvenile fish caught in the purse seine fishery are counted against the 4 VWX quota, whilst those caught in the weirs are considered to be of Subarea 5 origin. The recent US management plans (NEFSC 1998, 2004) assumes that all of the juvenile herring from this fishery originate from the US "coastal complex" $(5 Y+5 Z)$ which is reported to be at record high levels of abundance.

## 6) $5 Z$ Georges Bank

The activities of a single midwater trawler on the Canadian portion of Georges Bank (area 5Z) have also been included (Table 1). There were a total of only 16t reported from Aug. and Sept. from two landings. These catches were dominated by the 1999 year-class at age 5 in numbers and weight (Table 37).

## Acknowledgements

The authors would like to thank the following for their invaluable contributions to the provision of survey data and other assistance in the preparation of this report: Atlantic Herring Co-Op; Cape Breeze Seafoods; Comeau's Sea Foods Ltd.; Connors Bros. Ltd.; Herring Science Council; Eastern Shore Fishermen's Protective Association; Glace Bay herring gillnet group; Little Hope Management Committee; Scotia Garden Seafood Inc. and South-West Seiners.

| Annual landings by purse seiners are defined for the period from October 15 of the preceding year to October 14 of the current year. *Adjusted totals includes misreporting adjustments for 1978-84 (Mace 1985) and for 1985-93 (Stephenson 1993, Stephenson et al 1994) <br> All landings by other gear types are for the calendar year. |  |  |  |  |  |  |  |  |  |  |  |

Table 28. An evaluation of 2003-2004 fishery observations for the SW Nova Scotia/Bay of Fundy spawning component progress against biological objectives in the management plan for the fishery.

|  | Objective | 2003: Met | 2003: Not Met | 2004: Observations |
| :--- | :--- | :--- | :--- | :--- |
| $\mathbf{1}$ | Maintain reproductive <br> capacity |  |  |  |
| 1a | Persistence of all <br> spawning components | German Bank and Scots <br> Bay OK; Trinity <br> recovering | Limited signs of Seal Island component <br> Increased fishing on juveniles of mixed <br> origin inconsistent with this objective | Trinity reduced from 2003; no reports <br> from Seal or Lurcher areas |
| 1b | Maintain biomass of <br> each component | German Bank and Scots <br> Bay | Trinity Ledge and Seal Island <br> composition | Not met in all areas Few fish older than <br> age 7; only 20\% 4+. Rapid decline of <br> year-classes (including strong 1998 <br> year-class) |
| 1c | Maintain brod age | Further decline in proportion of older <br> ages |  |  |
| 1d | Maintain long spawning <br> period | German Bank and Scots <br> Bay | Trinity and Seal Island <br> Prevent growth over- <br> fishing | Fishing mortality at or <br> below F0.1 |
| 2a | Landings in recent years <br> less than 20\% of <br> surveyed SSB | High total mortality and targeting of 2 <br> year olds | High exploitation rate for Scots Bay. <br> May be higher than F0.1 if survey SSB <br> is overestimated. |  |
| 3 | Maintain ecosystem <br> integrity I ecological <br> relationships | Maintain spatial and <br> temporal diversity of <br> spawning | German Bank and Scots <br> Bay | Insufficient spawning at Seal Island and <br> Trinity Ledge |
| 3a | Maintain biomass at <br> moderate to high levels | Acoustic surveys <br> indicate moderate SSB | Nonger period for Scots |  |

# 2004 4WX Herring Fishery: Report of Fleet Activity 

L.M. Annis<br>Herring Science Council<br>P.O. Box 517, Yarmouth, NS, B5A 4B4

The herring industry in association with the Herring Science Council provides an annual summary of seiner fleet activity throughout the fishing season. This gives a general overview of the activities of the purse seine fleet and highlights important anecdotal information that may otherwise be lost. Information was gathered through association records, captain's reports and comments, through HSC and DFO staff, and from DFO landings and sample databases. The following is a summary of the activities for the 2003-2004 quota year purse seine fisheries.

## Offshore/ Scotian Shelf Banks

Summary

- Reactivated fishing area since 1996
- The 2004 Offshore/Scotian Shelf purse seine fishery took place on Weeks 22, 23, 24, 25.
- A grand total of $4,054 \mathrm{t}$ of herring was caught on the offshore banks, which was an increase from 2003 at 722 t caught.
- Weather was described as poor for the majority of the 2004 Offshore/Scotian Shelf fishery.

Week 22: May 30- June 5
Several boats fished the Offshore Banks this week. The fish were staying up in the water in this area. 151 t was landed from 3 slips this week on the Offshore Banks. Earlier in the week the weather was not that good. Fish size was reported to be between 10.5 and 12 inches.

Week 23: June 6 - June 12
The week started out with many boats making landings. In some parts of the week, the fish were staying on bottom and then the weather was not great again. 1987 t of herring was landed from 25 slips on the Offshore Banks

Week 24: June 13 - June 19
Eight seiners fished the Offshore Banks this week. The weather was quite windy. It was noted that fish were staying deep in the water column this week. 668 t was landed from 11 slips on the Offshore Banks. The fish caught ranged in size from 10-11 inches, and were for the food market. This week it was discussed if a survey could be done on the Offshore Banks, there was not a survey conducted this year.

Week 25: June 20 - June 26
Nine to ten boats fished the Offshore Banks this week. The week began with poor weather. Fish were again staying deep in the water. The fish size was between 10-11 inches and in food condition. 1248 t was landed from 15 slips on the Offshore Banks.

## South West Nova Scotia Component

The quota year for South West Nova is from the period October 15 to the following October 14, and so catches from October 15 to December 31, 2003 are included in the quota total. The 2004-year fishing weeks are summarized separately below.

## Summary

- The purse seine fleet concentrated their efforts on pre-spawning aggregations mainly on the Long Island Shore, the Grand Manan Banks, Gannett Dry Ledge, and Lurcher.
- Spawning aggregations were targeted on German Bank and Scots Bay.
- Weeks 1-5 showed activity in NB Coastal and the Grand Manan Banks. This was different from 2003, where activity was shown in weeks 1-8.
- Fishing started later in the spring at week 19: May 9-May 15, compared to 2003 when they started in Week 18: April 27- May 3, and 2002 when the fishery started at Week 16: April 13-19.
- The weather varied across the season with good weather and poor weather throughout.
- In May about 29\% of landings came from the Gannet Dry Ledge, June the majority of landings were from Lurcher Shoal at 32\%, July the greatest was 29\% from German Bank. In August 85\% of the landings came from Scots Bay. September the majority was from Scots Bay at $39 \%$ with landings from German Bank at 30\%. The month of October had $54.3 \%$ of landings were from the German Bank.

## 2003 Fishing Weeks

Week 42: October 19- October 25
This week 8 landings ( 331 t) were made from Grand Manan, 221 t were caught from 4 landings on the Long Island Shore, and 670 trom 12 landings were made from NB Coastal. Four landings of herring were made from German Bank, resulting in 153t.

Week 43: October 26- November 1
114 t of herring was landed from four landings at Grand Manan, and 509t was landed from 16 landings in NB Coastal.

Week 44: November 2- November 8
545 t of herring was landed from 13 landings at Grand Manan, and 465t was obtained from 8 landings in NB Coastal.

Week 45: November 9- November 15
This week 25 t was obtained from one landing at Grand Manan, 103 t landed from one landing on the Long Island Shore, and 245 t from 5 landings in NB Coastal.

Week 47: November 23- November 29
99 t were landed from one landing at Grand Manan, and 352 t were landed from four landings on the Long Island Shore.

Week 48: November 30- December 6
5 landings were made on the Long Island Shore this week which resulted in 257 t of herring.

Week 50: December 14- December 20
One landing was made this week at Grand Manan which resulted in 57 t of herring.

## 2004 Fishing Weeks

Week 1: January 4- January 10
662 t of herring were landed at Grand Manan from 20 landings and 336 t of herring was landed from 6 landings in NB Coastal.

Week 2: January 11- January 17
172 t of herring was landed from 7 landings that were made at Grand Manan.
Week 3: January 18- January 24
One landing was made this week in NB Coastal that resulted in 40 t of herring.
Week 4: January 25- January 31
89 t of herring were landed from one landing in NB Coastal this week.
Week 5: February 1- February 7
182 t of herring was landed from 10 landings made at Grand Manan, and 12 t of herring was obtained from one landing in NB Coastal.

Week 19: May 9- May 15
This week seining activity resumed in $4 W$. 853 t was landed from a total of 19 slips from Gannet Dry Ledge.

Week 20: May 16- May 22
Two landings were made from Grand Manan (166 t), 11 landings were made from the Long Island Shore (503 t), 9 landings were made from Lurcher Shoal (363 t), 6 landings came from Gannet Dry Ledge (263 t), and 5 landings came from German Bank (242 t).

Week 21: May 23- May 29
This week 828 t of herring was landed from Grand Manan (21 slips), 495 t was obtained from the Long Island Shore (15 slips), and 173 t was caught from Lurcher (3 slips).

Week 22: May 30- June 5
845 t was obtained from Grand Manan this week from a total of 21 landings. 486 t was landed from the Long Island Shore (14 landings), and one landing was made at Lurcher to yield 75 t of herring.

Week 23: June 6- June 12
Eight landings were made this week, seven from Grand Manan (220 t) and one from Lurcher (72 t).

Week 24: June 13- June 19
Eight landings on Lurcher this week caught a total of 458 t of herring. 12 landings on the Long Island Shore were to yield 295 t of herring, and two landings on Gannet Dry Ledge

Week 25: June 20- June 26
21 landings ( 837 t ) were made from Long Island Shore, 4 landings (203 t) from Gannet Dry Ledge, and 7 landings ( 373 t) from German Bank.

Week 26: June 27- July 3
2 landings (167 t) was made from Gannet Dry Ledge, 17 landings ( 526 t ) were made from the Long Island Shore. 35 landings ( 3187 t ) were made from Lurcher Shoal and nine or ten boats were active in this area. Fish ranged in size from 10-12 inches. Water temperature was about 53 degrees Fahrenheit. Most boats got the fish they needed this week. There were repots this week that 3-4 miles of herring was located in Bay Lobster and Pubnico Point in the shoal water. SW winds provided good weather this week.

Week 27: July 4- July 10
This week two landings were made from Grand Manan resulting in 41 t of herring. 448 t was caught from 14 landings on the Long Island Shore, 1589 t of herring was also caught from 20 slips from Lurcher, 1493 t was caught of 17 landings on Gannet Dry Ledge, and one landing was made from German Bank of 5 t . Toward the start of the week most boats got their fish. Fish were ranging in size from 10-12 inches. On July 7, the fish moved out of the area, heading North. There was between 15 and $25 \%$ small fish in landings on various days this week. Overall, the weather was good this week.

Week 28: July 11- July 17
This week German Bank was very active with 38 landings and 3351 t of herring landed. Between nine and eleven boats fished German Bank this week. Fish were showing on bottom in the daytime and then moving up in the water at night. As many as 20 whales were reported in this area. Fish size was between 10-12 inches. 117 t from 2 landings were landed from Gannet Dry Ledge, 163 t was landed from 8 landings on Long Island Shore, and 207 t was landed from 7 landings on Grand Manan. It was reported that there was a good body of fish in the shoal water inside of German Bank. There was
some windy weather this week, and on July 13th many boats did not go out for the night. Also toward the end of the week, fish were staying deep in the water at night.

Week 29: July 18- July 24
Herring was staying deep on German Bank this week, making them impossible to catch. The weather was also a factor on several days this week with high winds. One landing of 84 t was made on Gannet Dry Ledge, 17 landings ( 581 t ) was made on Grand Manan, 6 landings (159 t) were made on the Long Island Shore, and Scots Bay was targeted with 7 landings resulting in 435 t of catch. However it was reported that there was 4-6 miles of fish on bottom all over the rip on July 20th. Fish was both lean and in food condition. Fish size ranged from 10-11 inches. Sets in Scots Bay showed the herring was mixed.

Week 30: July 25- July 31
One landing was made on German Bank which resulted in a catch of 32 t .530 t from 15 landings was caught in Grand Manan, and 884 t from 19 landings were caught on the Long Island Shore. 22 landings were made in Scots Bay which resulted in 1678 t of herring caught. Up to eight boats fished Scots Bay this week. The fish were showing up at surface in small bunches. The larger fish were good roe fish, and the smaller fish in the sets were hard. The weather was good this week.

## Week 31: August 1- August 7

One landing of 15 t was made in Grand Manan, and 25 landings were made on the Long Island Shore which resulted in 834 t of herring. Eleven boats fished Scots Bay this week. 39 landings were made in Scots Bay with a total amount of 3103 t of herring caught. The weather was good for fishing. There was not a lot of fish showing, and they were showing up in small bunches. Again, the catches were mixed with larger roe fish and smaller hard fish. Due to rough weather, the first survey of Scots Bay was postponed from August 1st to August 2nd this week. During the survey the fish were showing in small bunches, and the survey, there seemed to be more fish showing. All boats were able to land fish after the survey.

Week 32: August 8- August 14
102 t of herring was landed from 4 landings on Grand Manan, and 32 landings were made on the Long Island Shore which resulted in 944 t of herring. Scots Bay was fished with a total of 46 slips and 3181 t of herring caught.

Week 33: August 15- August 21
286 t of herring was landed from 14 landings on Grand Manan, 219 t of herring was landed from 10 landings on the Long Island Shore, and 3 landings were made on German Bank resulting in 124 t of herring. 45 slips were from Scots Bay with a total of 4018 t of herring. Fish on German Bank were staying on bottom, and the seawater temperature was cold, at 48.9 degrees Fahrenheit. Fish caught on German Bank were mixed and small at 7-10 inches. In Scots Bay this week there was a good amount of fish, and all boats were able to make their sets in the area. The fish were bigger, and they are saying there was more fish on Aug 18th than on the survey. Fish were still
mixed this week. Up to 12 boats fished Scots Bay this week. The second survey of Scots Bay was cancelled for the night of August 15th due to poor weather, but was carried out on the night of August 16th.

Week 34: August 22- August 23
Six landings (103 t) were made on Grand Manan, five landings ( 217 t ) were made on the Long Island Shore, and 68 landings (5465 t) were made in Scots Bay. Up to 15 boats fished Scots Bay this week. Fish were again mixed, some roe fish and some hard. Fish size ranged from 10-11 inches. A few boats searched German Bank this week, and reported that the fish are staying hard on bottom or not coming there at all.

Week 35: August 30- September 4
The weather was good for fishing this week. 40 t (3 landings) were landed from Grand Manan, 20t (2 landings) from the Long Island Shore, 402 t (3 landings) from German Bank, and 3655 t (54 landings) from Scots Bay were landed this week. The third survey of Scots Bay was held this week. After the survey all boats landed fish. Reports from German Bank were that there was lots of fish on bottom at the spawn tow. The first survey of German Bank was held this week, the fish on German Bank was reported as roe fish with some hard. A good showing of fish was seen on the normal 'tow' area and everybody was able to catch their market. There was also some fish seen in the southern portion of the survey area and a large but narrow band (1-2 fathoms) of fish on bottom in the northwest portion of the survey area.

Week 36: September 5- September 11
3 landings ( 86 t ) were made on the Long Island Shore, 1 landing ( 41 t ) was made on Lurcher Shoal, 5 landings (187 t) were made from Gannet Dry Ledge, 9 landings ( 567 t ) were made from German Bank, and 21 landings (1040 t) were made from Scots Bay.

Week 37: September 12- September 18
11 landings ( 344 t ) were made on Grand Manan, 1 landing of 17 t was made on the Long Island Shore, 2 landings of 120 t was made at Trinity Ledge, 14 landings (527t) were made on Lurcher Shoal, and one landing of 44t was made on Gannet Dry Ledge. 27 landings resulted in 2005 t of herring from Scots Bay. German Bank had 7 landings of a total of 527 t of herring, and 3 landings of a total of 40 t of herring were made from Browns Bank. The second survey of German Bank was conducted this week, September 16th.

Week 38: September 19- September 25
13 landings (288 t) were made on Grand Manan, 13 landings ( 512 t ) were made on the
 made at Lurcher Shoal, 9 landings ( 718 t ) were made at Gannet Dry Ledge, 15 landings (1496 t) were made on German Bank, and 8 landings resulted in 289 t being caught from Scots Bay.

Week 39: September 26- October 2
37 t of herring was landed from 2 landings in Grand Manan, 1401 t was landed from 36 landings on the Long Island Shore, one landing of 38 t was made at Trinity, 218 t from 4 landings was made from Gannet Dry Ledge, and 2270 t was landed from a total of 26 slips on German Bank this week. The third survey of German Bank was conducted this week on September 30th. Some seiners fished through the weekend, with some companies taking fish from seiners though the weekend.

## Week 40: October 3- October 9

There was very good roe fishing on German. This was primarily on the spawn tow area at the start of the week but as the week progressed it extended further south to the tongue ground area. Two landings (161) were made from Grand Manan, 61 landings (3022 t) were made from the Long Island Shore, one landing of 19 t was made from Lurcher, and 2332 t was caught from 23 landings on German Bank.

Week 41: October 10- October 14
Some seiners fished over the Thanksgiving weekend. The focus became more on small fish than roe fish as the season end neared. There were also fewer boats in the fishery as some reached the end of their quota. This week there were no visible large aggregations of herring on German Bank. Where boats went to look for small fish, some small fish was caught. 561 t was landed from 14 slips on Grand Manan, 36 t was landed from 3 slips on the Long Island Shore, and 25 landings on German Bank produced 2301 t of herring. One landing of 5 t was also made on Browns Bank.

## Acknowledgements:

A sincere thank you is extended to all captains who provided me with information throughout the fishing season. Thanks to Donna Larkin of South West Seiners Co. Ltd., Joy Fry of the Atlantic Herring Co-op, and Jay Lugar from the HSC for all of their help in producing this document. A special note of thanks to Captain Glenn d'Eon for providing me with fishing activity reports throughout the fishing season.
