ABSTRACT

This is primarily a by-catch fishery and the data base does not permit a precise analytical assessment. Catch curves suggest that removal levels of 8,000-10,000 $t$ in the late 1960's and 1970's produced mortality rates of 0.30 to 0.35 which are above $\mathrm{F}_{0} .1(0.24)$. The stock now appears to be in a relatively stable condition and hence a TAC of 5,000 should be continued for 1983.

RESUME

Cette pêche est constituée surtout de prises accessoires et la base de données ne permet pas de faire une évaluation précise. Les courbes indiquent, en raison des prises de 8000 à 10000 t réalisées à la fin des années soixante et soixante - dix, que le taux de mortalité se situait entre 0,30 et 0,35 , valeurs supērieures au $\mathrm{F}_{0,1}(0,24)$. Le stock semble actuellement relativement stable, si bien qu'on devrait maintenir le TPA à 5000 t pour 1983.

## INTRODUCTION

This stock has been under quota management since 1973. Catches and TAC's are listed in Table 1. This fishery has been almost entirely by Canada since 1970. Nominal catches averaged around 9,200 t 1967-73 and about 4200 t 1974-81. Although this fishery is primarily a by-catch fishery there has been some directed catch also (Table 2).

## ASSESSMENT

Catch rates have remained relatively stable (Table 2 ) in the past several years, although the amount of directed effort was rather small.

Results of research vessel surveys are listed in Table 3. These are abundance estimates (numbers) from a group of selected strata within the American plaice depth range that have been fished each year since 1973. The large fluctuations indicated in the total abundance make these results rather suspect in a population consisting of such a large number of year-classes.

A catch curve using commercial catch numbers-at-age per unit effort (Fig. 1) for 1978-81 commercial data indicated average fishing mortalities of about 0.30 to 0.35 in the fully recruited age groups (assuming $M=0.20$ ). This mortality rate probably reflects removals of about 8,000 to $10,000 \mathrm{t}$ annually. F 0.1 for this stock has been calculated at 0.24 (Brodie and Pitt, 1981), hence a TAC of $5,000 \mathrm{t}$ would seem appropriate. The data base is not
available to permit a precise analytical assessment. It should be emphasized again that this is primarily a by-catch fishery and the catch level will perhaps be a function of the otter trawler fleet effort particularly in the 3Ps cod fishery.
