* This series documents the scientific basis for the evaluation of fisheries resources in Canada. As such, it addresses the issues of the day in the time frames required and the documents it contains are not intended as definitive statements on the subjects addressed but rather as progress reports on ongoing investigations.

Research documents are produced in the official language in which they are provided to the Secretariat.

This document is available on the Internet at:

<http://www.dfo-mpo.gc.ca/csas/>

* La présente série documente les bases scientifiques des évaluations des ressources halieutiques du Canada. Elle traite des problèmes courants selon les échéanciers dictés. Les documents qu'elle contient ne doivent pas être considérés comme des énoncés définitifs sur les sujets traités, mais plutôt comme des rapports d'étape sur les études en cours.

Les documents de recherche sont publiés dans la langue officielle utilisée dans le manuscrit envoyé au Secrétariat.

Ce document est disponible sur l'Internet à:

ABSTRACT

Fishery removals from the Western pollock stock component ($4X_{opqrs}+5Y_b+5Z_c$) averaged 6000 t since 2000 and contributed 92% of total landings in 2005. Mobile gear catch rates in 2006 were at the second lowest level in the time series. Catch rates for 2005 and 2006 were not comparable to those observed earlier in the time series when quotas were not limiting. The 2006 RV biomass index was at the highest observed level in the time series, and although this was an obvious year effect, there has been a general increasing trend since 2003. Other surveys indicated a general trend of increasing rather than decreasing abundance for pollock and supported recent trends from the DFO RV survey. Fishery weights at age, which are used as a proxy for population age 5+ weights at age, have been decreasing since about 1984. RV survey weights at age for these age groups did not show this same declining trend, indicating that the fishery weights may be influenced by changes in fishing patterns. Using a Modified Base VPA (which excludes 2005 and 2006 from the catch rate index), age 4+ biomass has increased from a low of about 7500 t in 2000 to 30000 t in 2006. The 2001 year class is estimated at nearly 15 million recruits and is the strongest since the 1980 year class. Reduced quotas and harvests have contributed to a decline in fishing mortality rates on ages 6-9, which is now just below the F_{ref} of 0.2. The range of harvest strategies in the 2007/2008 fishing year that are risk averse (25% risk of exceeding F_{ref}) to risk neutral (50% risk of exceeding F_{ref}) are about 4400 t to 5300 t.

Landings from the Eastern Component ($4X_{mn}+4VW$) traditionally come from the Tonnage Class (TC) 4+ sector, and have been following a declining trend. Since 1993, much of the Eastern Component was closed to cod-directed fishing, which further reduced pollock landings from that area. Research vessel (RV) summer survey biomass, while variable, has been declining since the late 1980s and is now at the third lowest level in the time series. Large scale directed pollock fisheries should not be considered until the Eastern Component rebuilds.

RÉSUMÉ

Les prélèvements de goberge dans le stock de la composante ouest ($4Xopqrs+5Yb+5Zc$) affichent une moyenne de 6000 t depuis 2000 et ont représenté 92 % des débarquements totaux en 2005. En 2006, les taux de prises pour les engins mobiles ont été les deuxièmes plus faibles de la série chronologique. Les taux de prises de 2005 et de 2006 n'étaient pas comparables à ceux observés précédemment dans la série chronologique, lorsque les quotas ne constituaient pas un facteur limitatif. En 2006, l'indice de la biomasse dérivé des relevés des navires de recherche (NR) a été le plus élevé jamais enregistré dans la série chronologique et, même s'il s'agissait de toute évidence d'un effet propre à cette année-là, on observe une tendance générale à la hausse depuis 2003. D'autres relevés indiquent que l'abondance de la goberge affiche une tendance générale à la hausse plutôt qu'à la baisse et viennent appuyer les tendances récentes observées dans les relevés des NR du MPO. Les poids des prises selon l'âge, lesquels sont utilisés comme valeur approximative pour le poids des individus d'âge 5+, diminuent depuis 1984 environ. Les poids selon l'âge dérivés des relevés des NR pour ces catégories d'âge n'ont toutefois pas montré cette tendance à la baisse, ce qui signifie que le poids des prises peut varier selon les régimes de pêche. Lorsqu'on a utilisé une analyse des populations virtuelles (APV) à base modifiée (qui exclut les années 2005 et 2006 de l'indice du taux de prises), la biomasse de l'âge 4+ est passé d'un creux d'environ 7500 t en 2000 à 30 000 t en 2006. On estime que la classe d'âge de 2001 compte à presque 15 millions de recrues et qu'elle est la plus forte depuis la classe d'âge de 1980. La baisse des quotas et des prises a contribué à la diminution des taux de mortalité par la pêche chez les individus des âges 6 à 9; ce taux est maintenant tout juste inférieur au niveau Fréf. de 0,2. Les stratégies d'exploitation à faible risque (25 % de risque de dépassement du niveau Fréf.) ou à risque neutre (50 % de risque de dépassement du niveau Fréf.) chiffreront les prises entre environ 4400 et 5300 t durant l'année de pêche 2007/2008.

Les débarquements de la composante est ($4Xmn+4VW$) sont d'ordinaire effectués par la catégorie de jauge (CJ) 4+ et affichent une tendance à la baisse. Depuis 1993, la pêche dirigée à la morue est fermée dans une grande partie de la composante est, ce qui réduit encore davantage les débarquements de goberge en provenance de cette composante. La biomasse dérivée des relevés des NR d'été, quoique variable, diminue depuis la fin des années 1980 et est maintenant la troisième plus faible de la série chronologique. Il ne faut pas envisager la pratique de pêches dirigées à la goberge à grande échelle au sein de la composante est avant que celle-ci se rétablisse.

INTRODUCTION

Pollock in the management unit 4VWX and 5Zc are assessed as a Western (5Zc, 5Yb, 4Xopqrs) and Eastern component (4Xmn, 4VW), following the recommendations of the Framework Assessment completed in 2004 (Neilson et al. 2004) (Fig. 1). This paper updates the last stock assessment for pollock in the Western Component completed by Neilson and Perley (2005) and includes updated information for 2005 (fishery data: Trimester 3) and 2006 (survey data and fishery data: Trimesters 1&2).

Advice was requested by Fisheries and Aquaculture Management on the stock status of pollock to inform management of the 2007/2008 fishery. The Terms of Reference for the Science Advisory Process Scientific Peer Review were to:

- Examine available data from various sources (e.g. surveys, commercial fishery and at-sea observer) for consistency with model predictions on population structure and industry observations, and recommend requirements for new information, monitoring or improved data collection.
- Update the advice using framework methodologies and the latest information from fisheries and research surveys.

THE FISHERY

Landings of pollock for the entire management unit in the fishing year ending March 31, 2006 were 6286 t against a quota of 6500 t (Fig. 2). Landings from April 1 through November 3, 2006 are 2651 t against a quota of 4500 t. Peak landings in 1987 were 46000 t but since 1999 they have been less than 10000 t. The TAC has rarely been restrictive except for a five year period in the late 1980s and more recently since 2004 (Fig. 2). Calendar year landings for 2005 were 7528 t and for 2006 (1 Jan. - 31 Aug.) were 2903 t (Table 1).

The pollock fishery has had significant changes in both area fished and in dominant gear type. The Western Component of the management unit usually contributes the largest proportion of the total landings (92% in 2005) (Fig. 3; Table 2). Landings from the Eastern Component traditionally come from the TC 4+ sector, and have been following a declining trend (Fig. 3; Table 3). Since 1993, much of the Eastern Component was closed to cod-directed fishing, which further reduces pollock landings from that area. Landings from the Western Component now come mostly from three unit areas (4Xp, 4Xq and 5Zc), whereas as recently as 1997, landings were spread among different unit areas to a greater extent (Fig. 4; Table 2). The seasonal pattern of the fishery in 2006 was similar to previous years, with most pollock catches occurring in summer months (Table 4).

Mobile gear catches (OTB 1-3) in 2006 occurred in outer Bay of Fundy, Crowell and Jordan Basins, northeastern Georges Bank and east of La Have Bank,

while gillnet catches were mostly from the Crowell/Jordan Basin areas (Fig. 5). The distribution of catches was similar to last year but with proportionately more catch in 4Xq in 2006. As indicated by Neilson and Perley (2005), the overall distribution of catches in recent years has contracted since the early 1990s.

Since the early 1980s the small mobile gear component (OTB 1-3) has accounted for most of the total landings, with a notable increase after 2001 (Fig. 6; Table 5). The percentage of total landings taken by gillnets has declined since 2000, however, in 2006 the gillnet share increased to 30% while small mobile declined to 63%. The contribution of larger trawlers to total landings (OTB 4+) has been steadily declining since 1988, but showed a modest increase from 2% in 2005 to 6% in 2006. The offshore sector is now using smaller vessels (TC 1-3, under the Temporary Vessel Replacement Program) to catch their allocation. Longline/handline landings continued to represent a small proportion of total catches and in 2006 were < 2%.

Industry Perspectives

The poor status of the pollock resource as described by the 2005 assessment is completely inconsistent with the perception of industry. During the Data Input Review meeting in Yarmouth (Oct. 23, 2006), fishermen reported that all gear sectors were seeing abundant signs of pollock in 2006 throughout the stock area, despite the fact that they were trying to avoid this species due to the low quota. They expressed concern over the usefulness of the commercial catch rate series as an index of abundance. Under current quota restrictions, most fishermen are avoiding pollock as much as possible and recent catch rates (i.e. 2005 and 2006) would not be comparable to those observed earlier in the time series when quotas were not limiting. Fishermen have also indicated that there are very few "pollock directed" trips now compared to the past (possibly only a few vessels actually direct for pollock now) so that not many trips would qualify for inclusion in the catch rate series. Further, they expressed concern over the lack of summer survey coverage on the Canadian portion of Georges Bank, an area that has become increasingly important to the fishery in recent years. There have also been reports of discarding of pollock in 2006, but the extent of this problem is not known.

SAMPLING AND CATCH/WEIGHT AT AGE

Port (shore) and observer (at-sea) sample collections contributed to over 21,000 and 16,000 pollock length measurements in 2005 and 2006 (Jan. 1- Aug. 31), respectively (Table 6). Sampling in 2005 and 2006 was considered adequate to characterize the catch at size and catch at age, with 1287 ages available for the 2005 fishery and 685 ages available to the end of the second trimester in 2006.

Comparisons of port and observer length measurements of pollock were made for months, areas and gear types where both types of samples were

available (Fig. 7). Both sample sources showed similar size compositions of pollock and indicated that discarding of smaller sized fish (high-grading) was not apparent during these trips. Lack of sufficient observer coverage both spatially and seasonally precluded the estimation of discards from the 2006 fishery.

The level of commercial fishery sampling was relatively low in the 1970s in NAFO Division 4X, thus the assessment presented here starts in 1982 when the level of sampling improved to reflect the fishery more accurately. To construct the catch at age (CAA) for 2006 (Trimesters 1 and 2) and update the CAA for 2005 (with data from Trimester 3), data for the Western Component were aggregated to the trimester level by gear type and tonnage class. Area 4Xu was prorated over the Western Component by allocating the proportion of landings attributed to 4Xmn versus the remaining unit areas in 4X. Samples were aggregated on a trimester basis for OTB 1-3 large mesh (cod end mesh > 110mm) and gillnet, and on an annual basis for OTB 1-3 small mesh (cod end mesh ≤ 110mm), OTB 4+, and longline/handline gear because of limited data. Small pollock are caught in the small mesh mobile gear used in the redfish fishery, so this gear type was kept separate in the CAA. Length-weight parameters were calculated from data pooled over the last ten years (1997-2006) from the summer research vessel (RV) survey for strata 474, 476 and 480-495 (the Western Component). Since no surveys were conducted in the spring or fall, the summer value is used for all three trimesters.

In general, larger pollock were captured by gillnet (mean = 66 cm Fork Length (FL)) compared to large and small mesh mobile gear (mean = 58 cm FL) (Fig. 8, upper panel). The small mobile gear captured a greater proportion of fish < 46 cm FL. The age composition of the catch differs among gear types, with predominant ages ranging from 5-8 for gillnet, 4-7 for large mesh mobile and 3-7 for small mesh mobile gear (Fig. 8, lower panel).

Strong and weak year-classes are apparent in the age structure and cohorts are readily tracked (Table 7, Fig. 9). Diminished numbers at age for older ages, a feature which first appeared in the 1990s, continues to the present. However, age 6 in 2005 (1999 year-class) was at its highest value since 1998. This strong year-class was first noted in the 2004 assessment. The 2006 fishery was dominated by ages 5 and 6, the 2001 and 2000 year classes, respectively. Catches up to the end of the second trimester were low due to reduced quota. For the 2006 fishery, ages 5-8 were above the ten year average from 1996-2005, while ages 3-4 were below the ten year average (Fig. 10). Ages 4 and 6 were above what was projected last year for the 2006 catch, and age 5 is close to projected amount.

In 2006, there was a slight increase in Weight at Age (WAA) for ages 4 and 6 and a slight decrease for ages 3, 5 and 7 (Table 8; Fig. 11). At the older ages there was an increase during the late 1990's, followed by a sharp decrease after 2002. In general, fishery weights at age have been decreasing since 1984, especially for ages 3-5 but they may be levelling off now. Fishery weights at age are used as a proxy for population age 5+ weights at age.

INDICES OF ABUNDANCE

Commercial Fishery Catch Rates

Commercial fishery catch rates (CPUE) for small mobile gear (TC 1-3) are used as tuning indices in this assessment and are based on individual standardized catch rates from four areas in the Western Component: NAFO Unit Areas 4Xq, 4Xp/5Zc, Bay of Fundy (4Xrs and 5Yb) and 4Xo. The main criteria for trips included in catch rate analyses is that they must be pollock directed (>50% of total catch is pollock) and the vessel must have five or more consecutive years in the fishery. A multiplicative model (Gavaris 1980, 1988a) with main effects of year (1982-2006), CFV number, month and cod end mesh type (diamond or square) was solved using standard linear regression techniques after \ln transformation of nominal CPUE (t/hr) data:

$$\ln(\text{CPUE}_{ijkl}) = \mu + \text{Year}_i + \text{Month}_j + \text{Vessel}_k + \text{Mesh Type}_l + e_{ijkl}$$

Analysis of variance results indicated that for each area, the overall regression and individual main effects were significant ($P < 0.5$) and that the model explained between 35-49% (multiple R^2) of the variability in the data. A weighting factor was applied to the standardized catch rates for each of the four areas to account for differences in trends, then they were averaged together to generate a single index for the Western Component. The weighting factor for each area was calculated as the number of productive 10' squares in that area in 1992 (a year of high landings) divided by the total number of productive 10' squares in all areas in 1992.

There has been a general declining trend in standardized catch rates for all areas since the early 1980s, followed by an increase in 2002 (Fig. 12; upper panel). The increase for 4Xp/5Zc continued to 2005 and then dropped off in 2006, while for the Bay of Fundy (BOF) and 4Xq, the decline began in 2004. The area-weighted CPUE for all areas combined is now at the second lowest level in the time series, the lowest occurring in 1998 (Fig. 12; lower panel). Catch rates in 2006 were constrained by reduced quotas and changes in fishing practices and appeared to be inconsistent with RV survey indicators.

The age-specific indices of abundance from the mobile gear sector of the fishery indicated a reduction in the abundance of older (ages 7+) fish since 1996 (Table 9; Fig. 13). In recent years, the 1999 year-class has been relatively strong, a trend which continued through to age 7 in 2006. The 2001 year class at age 5 was predominant in the series this year while early indications suggested that the 2003 year-class is weak.

DFO Research Vessel (RV) Survey

Indices from the summer DFO research vessel survey are also used in this assessment. The 2006 RV biomass index was at the highest observed level in the time series and although this was an obvious year effect, there has been a general increasing trend since 2003 (Fig. 14). Several good catches occurred in the Western Component area off southwestern Nova Scotia and in the outer Bay of Fundy, however catches in the Eastern Component continued to be very low (Fig. 15). Stratified area (sq mi) occupied by pollock in the Eastern Component has shown a more dramatic decline than the Western Component, especially after 2001 (60% decrease) (Fig. 16). While there has also been a decline in the Western Component it is not nearly as pronounced as in the east.

Consistent with the CPUE indices, the DFO RV indices showed that the 1999 year-class was strong in the 2003-2006 surveys and has resulted in improved numbers at age 7 in 2006 (Table 10, Fig. 17). The 2002 year class at age 4 is now much stronger than indicated last year, and the 2000 and 2001 year classes at ages 6 and 5 in 2006, respectively, have reached record high levels. Record high indices at all ages should be interpreted with caution since indices for all year classes are inconsistent with values seen previously.

RV survey weights at age (equivalent to mid-year population WAA) do not appear to have the same declining trend evident in the fishery weights at age for age 5+ (Fig. 18). Fishery WAA may be influenced by changes in fishing patterns.

Other Survey Indicators

The ITQ survey is not used as a tuning index but it provides qualitative information to compare with the DFO summer survey. In 2006 there were several good catches in 4Xpq (similar to the summer RV survey) but lower catches in the outer Bay of Fundy compared to the long term average (Fig. 19). There was also a large catch of small fish near the eastern boundary of the ITQ survey area in 4Xn. Trends in biomass indices for the ITQ and DFO summer surveys show some concurrence (Fig. 20). The ITQ survey biomass index does not show a large increase in 2006 but like the DFO survey biomass index, it gives an indication that biomass may be higher now than it was a few years ago. In contrast, the CPUE series indicates a trend of declining biomass in recent years.

The National Marine Fisheries Service (NMFS) has conducted stratified random surveys during spring and fall in the Gulf of Maine since the 1960s'. The 2006 NMFS spring and 2005 NMFS fall surveys show good catches in the western Gulf of Maine and moderate catches on northeastern Georges Bank (Fig. 21). The five year average for both series indicates that catches occur across the international boundary and that there is continuity with the Western Component in 4X. Both series, although not used for tuning indices in this assessment, indicate a trend of

increasing rather than decreasing biomass for pollock and support recent trends from the DFO RV survey (Fig. 22).

ESTIMATION OF CURRENT POPULATION STATE

Two Base VPA runs were conducted using the framework assessment formulation of Neilson et al. (2004) with a few modifications. The Base Model used CAA for ages 2-13 (1982-2006), CPUE indices for age 3-8 (1982-2006, power fit), RV indices for ages 3-8 (1984-2006, proportional fit) and natural mortality of 0.2. The Modified Base Model used the full RV series (1984-2006) but a truncated CPUE series excluding 2005 and 2006, years which had more restrictive quota and fewer pollock-directed trips. The adaptive framework, ADAPT (Gavaris1988b), was used to calibrate the sequential population analysis with the CPUE and RV survey age-specific abundance trend results. For this assessment, age 2 was assigned a fixed value based on recent observed recruitment and fishing mortality at age 9 for 2005 and 2006 was assumed to be equal to the population number weighted average fishing mortality on ages 7 and 8.

During the process of updating the mobile gear CPUE series, it was discovered that the weighting factor was incorrectly applied to the individual standardized series for each of the four areas. The Benchmark assessment method for applying the weighting factor involved *dividing* each area-specific standardized CPUE by the weighting factor for that area, which is not technically correct. The correct method involves *multiplying* the area-specific standardized CPUE by the weighting factor for that area. The end result is slightly lower catch rates prior to 1995, and slightly higher catch rates after 1995 (Fig. 23).

Using the Base VPA formulation, sensitivity runs were carried out to determine the impact that this change in CPUE calculation would have on age 2 recruitment, age 4+ biomass and age 6-9 F. In general, the difference in model results for recruitment, biomass and F are modest (Fig. 24). Age 2 recruitment and 4+ biomass are slightly more optimistic using the corrected method, with age 4+ biomass in 2006 estimated at 20500 t (vs 18500 t using the benchmark CPUE series). There was also a slight reduction in F on ages 6-9 in the VPA run using the corrected CPUE series. For this assessment, both the Base VPA and Modified Base VPA formulations use the corrected area weighting method for the CPUE series.

Comparison of Population Model Results

Age-specific residuals for the Base VPA are shown in Fig. 25. Residuals for the CPUE series were large and negative across all ages in 2006 (model predicts higher abundance than indicated by CPUE series) while for the RV series they were large and positive across all ages (model predicts lower abundance than indicated by survey indices). For the Modified Base VPA, residuals for the CPUE series in 2004 were large and negative for ages 3, 4, 7 and 8 (Fig. 26), but the magnitude was less than the Base VPA. Similarly, for the RV survey, there were large positive residuals on ages 4-6 in 2006, but comparatively not as bad as the Base model.

The population abundance estimates for the Base VPA show greater relative error in model fit and relative bias for ages 3 and 8 while the relative error for ages 4-6 is lower and the bias is smaller (Table 11). The population abundance estimates for the Modified Base VPA show a different pattern with high relative error and relative bias in model fit on ages 3 and 4 (Table 12). Survey calibration constants (q 's) for both VPA models increase with age up to age 7, then decline at age 8. While the age-specific estimates of population numbers and calibration constants are sometimes associated with high variance, they are comparable to those reported in the assessment of this resource in 2005.

A comparison of VPA model results indicates that age 2 recruitment for the 1999-2003 year classes is higher for the Modified Base VPA compared to the Base VPA (Fig. 27). Also, age 4+ biomass is higher from 2003 on and shows a steady increase to 2006. The 2006 4+ biomass is estimated at 30000 t (vs 20500 t for Base VPA). Fishing mortality on ages 6-9 is slightly lower in the Modified Base VPA and drops below F_{ref} in 2006. Results for population abundance, F and biomass are given in Tables 13-15, respectively for the Base VPA and in Tables 16-18 for the Modified Base VPA. The Modified Base VPA is considered to be a better approach because it excludes 2005 and 2006 from the catch rates series which are not considered to be comparable to other years in the time series.

Stock Trends and Current Status

The final assessment results were based on the Modified Base age-structured population model for the Western Component that incorporated indices of abundance from both the DFO summer research vessel survey (1984-2006) and standardized CPUE from the commercial fishery excluding the most recent two years (1982-2004). The 2001 year-class was estimated to be slightly higher than indicated last year and was the strongest at age 2 since 1980, followed by the 1999 year class (Fig. 28). Initial indications for both the 2002 and 2003 year-classes are that they are of moderate strength. Age 2 recruitment estimates for both the 2002 and 2003 year classes are at about 5 million recruits while the 2001 year class is estimated at 15 million.

Estimates of age 4+ (considered spawning stock) biomass declined from about 66000 t in 1984 to about 7500 t in 2000. Biomass has been rebuilding since 2000, increasing steadily to about 30000 t in 2006 (Fig. 28). Fishing mortality rates steadily increased from the early 1980s to above 1.0 by the early 1990s and remained high until the early 2000s. Subsequent reduced quotas and harvests have contributed to a decline in the fishing mortality rate on ages 6-9, which is now just below the F_{ref} of 0.2 (Fig. 29). The overall prognosis is considerably better than indicated from last year's assessment.

PROJECTIONS OF CATCH AND POPULATION BIOMASS

Projections were done using the Modified Base VPA results and used a 3-year average (2004-2006) for partial recruitment, fishery WAA and beginning of year WAA. The partial year (2006) was included in the calculations because in previous years, the increment of growth observed in the final trimester was inconsequential. Recruitment was set at 5 million for 2007 and 2008. It was assumed that removals for the remainder of quota year (March 31, 2007) would be about 1500 t with removals at F_{ref} for the next fishing year (2007/2008). The projected 4+ population biomass is estimated at 33402 t for 2007 and 36150 t for 2008. The projected 4+ yield in 2007 is estimated at 4887 t (Table 19) with the 2001 year class at age 6 representing 52% of the catch biomass.

For the Western Component, the range of harvest strategies in the fishing year that are risk averse (25% risk of exceeding F_{ref}) to risk neutral (50% risk of exceeding F_{ref}) are about 4400 t to 5300 t (Fig. 30). The population has a 50% likelihood of achieving a 10% increase in biomass over the 2007/2008 fishing year with removals as high as about 4400 t.

EASTERN COMPONENT

While most of the fishery now occurs within the Western Component, there remains a need to provide advice on the status of the resource on the Eastern Component. The distribution of catches from the 2006 RV survey is shown in Fig. 31. Only a few good catches of pollock occurred in 2006, all near the western boundary of the Eastern Component in 4Xn. The proportion of biomass from the eastern component in 2006 is about 2% of the total (Fig. 32) and total stratified biomass is now at the third lowest level in the time series since 1970. Smoothed estimates of total mortality from the RV survey remain high and have followed an increasing trend despite minimal landings (Fig. 33).

SOURCES OF UNCERTAINTY

The results of the assessment depend, in part, on indices of abundance from the commercial fishery. Trends in catch rates for 2005 and 2006 appear to be confounded by changes in the fishery and management practices not associated with trends in abundance. Further examination of this time series is required to ensure its future utility. Fishermen have also indicated that there are very few “pollock directed” trips now compared to the past (i.e. where pollock represent > 50% of catch by weight) so that not many trips would qualify for inclusion in the catch rate series. Pollock, being a semi-pelagic, schooling species, are less well sampled by the summer RV survey than other gadids. This creates high variability in the RV abundance index from year to year. There is a concern over the lack of summer survey coverage on the Canadian portion of Georges Bank, an area that has become increasingly important to the fishery in recent years. If the proportion of the population on Georges Bank has increased in recent years, the survey would underestimate the recent biomass series. Survey weights-at-age do not display the recent decline seen in fishery weights. The selection of weights at age is influential in population biomass estimates and recent trends are impacting on the calculation of biomass trends and reference points. Using survey weights at age could result in a greater proportional increase in biomass since 2000.

CONCLUSIONS AND ADVICE

For the Western Component, the range of harvest strategies in the fishing year that are risk averse (25% risk of exceeding F_{ref}) to risk neutral (50% risk of exceeding F_{ref}) are about 4400 t to 5300 t. This risk analyses does not incorporate the uncertainties as noted above and overstates the precision of the estimates of F_{ref} yield outcomes. Recommendations for the Eastern Component are the same as last year: “Large scale directed pollock fisheries should not be considered until the Eastern Component rebuilds”.

ACKNOWLEDGEMENTS

We thank the many members of the fishing industry who took time to participate in the process of stock assessment this year. We also thank MFD port samplers G. Donaldson and E. Williams for contributing sampling information, and Cecil Nelson for providing the ages. Kirsten Clark provided helpful editorial comments on an earlier draft of this document.

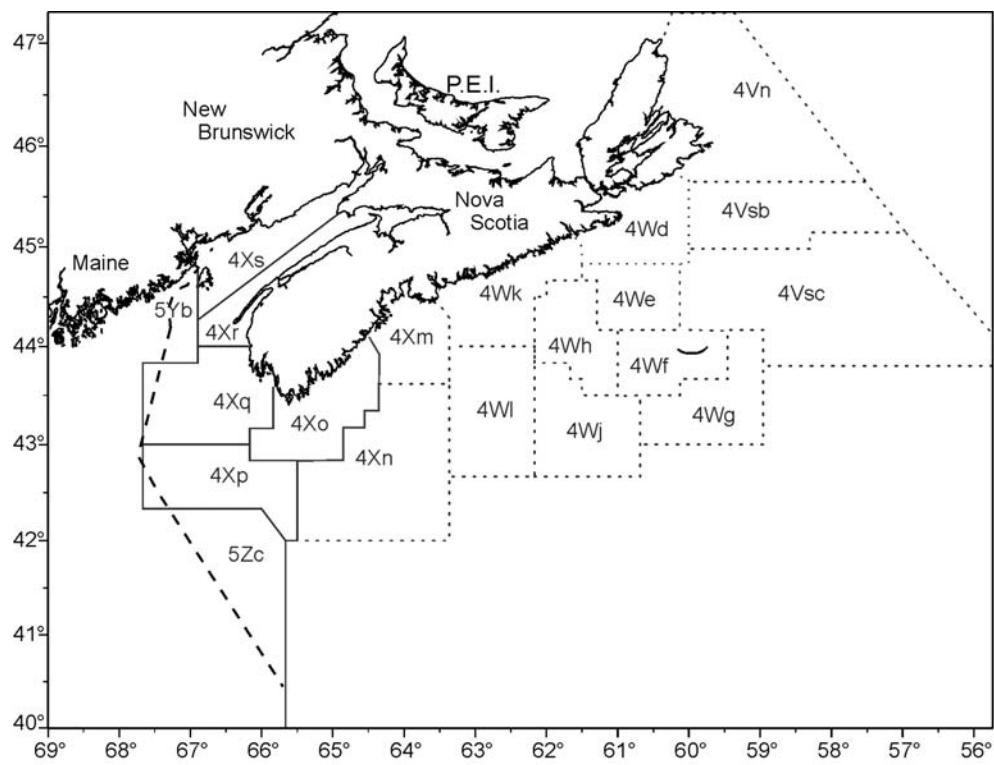

Fig. 1. DFO Statistical Unit Areas in the Scotian Shelf and Bay of Fundy and NAFO SubDivision 5Zc. Those areas forming the western component of pollock on the Scotian Shelf, Bay of Fundy and Georges Bank are outlined as solid lines, and those comprising the eastern component are shown dashed lines.

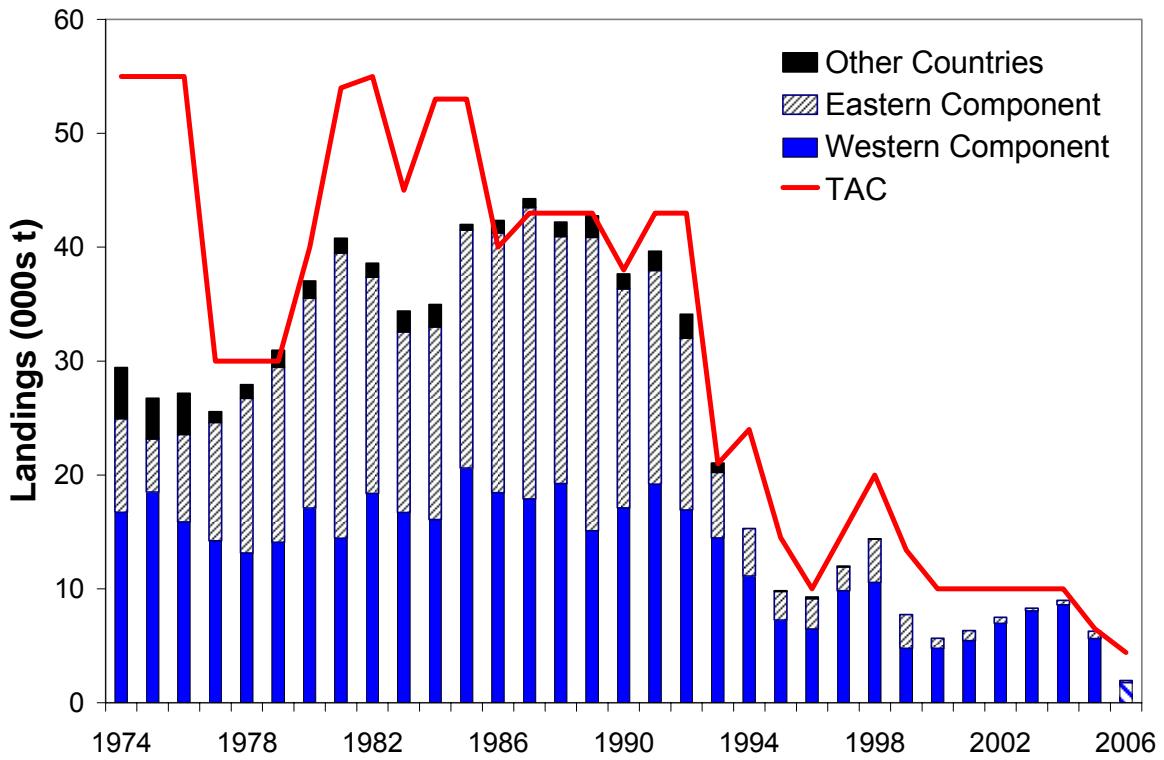

Fig. 2. Landings of 4VWX5Zc pollock, shown with respect to the Total Allowable Catch (TAC). The striped bar in 2006 signifies incomplete landings. Prior to 1999, the quota year was Jan. 1 to Dec. 31. In 1999, the quota year was Jan. 1, 1999 to Mar. 31, 2000. Subsequently, it is Apr 1 to Mar. 31. All landings are shown for quota years.

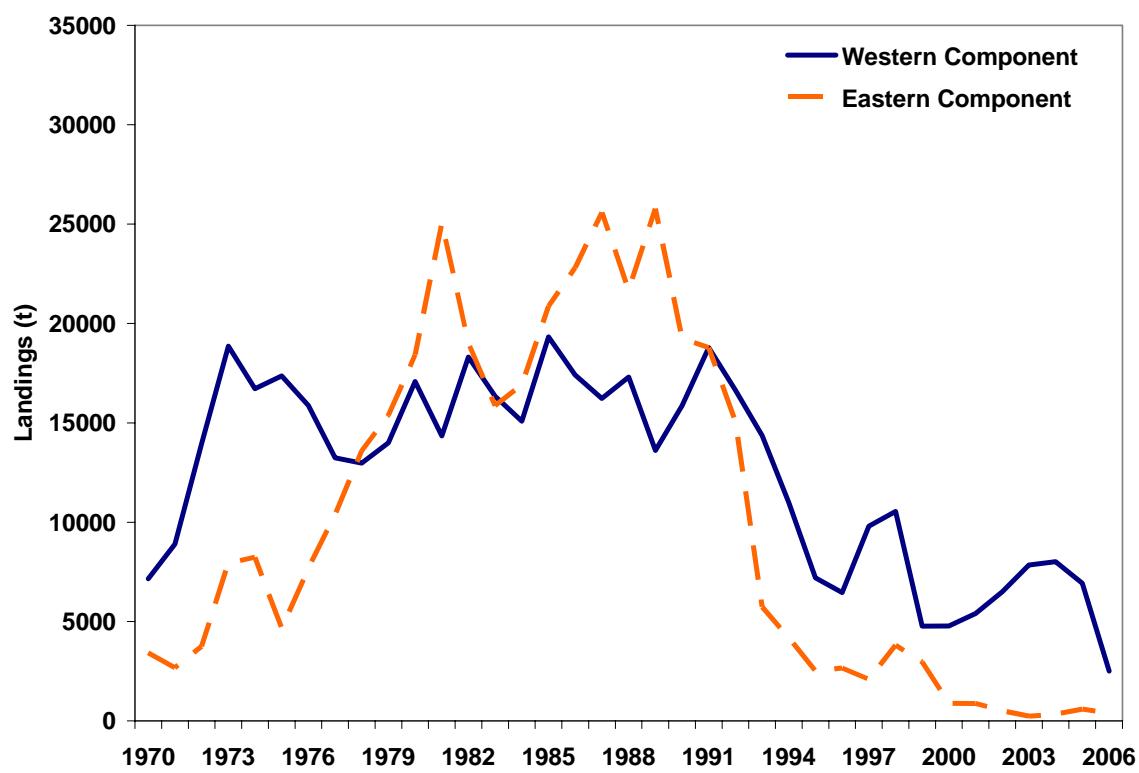

Fig. 3. Landings of pollock from the Eastern and Western Components, 1970-2006.

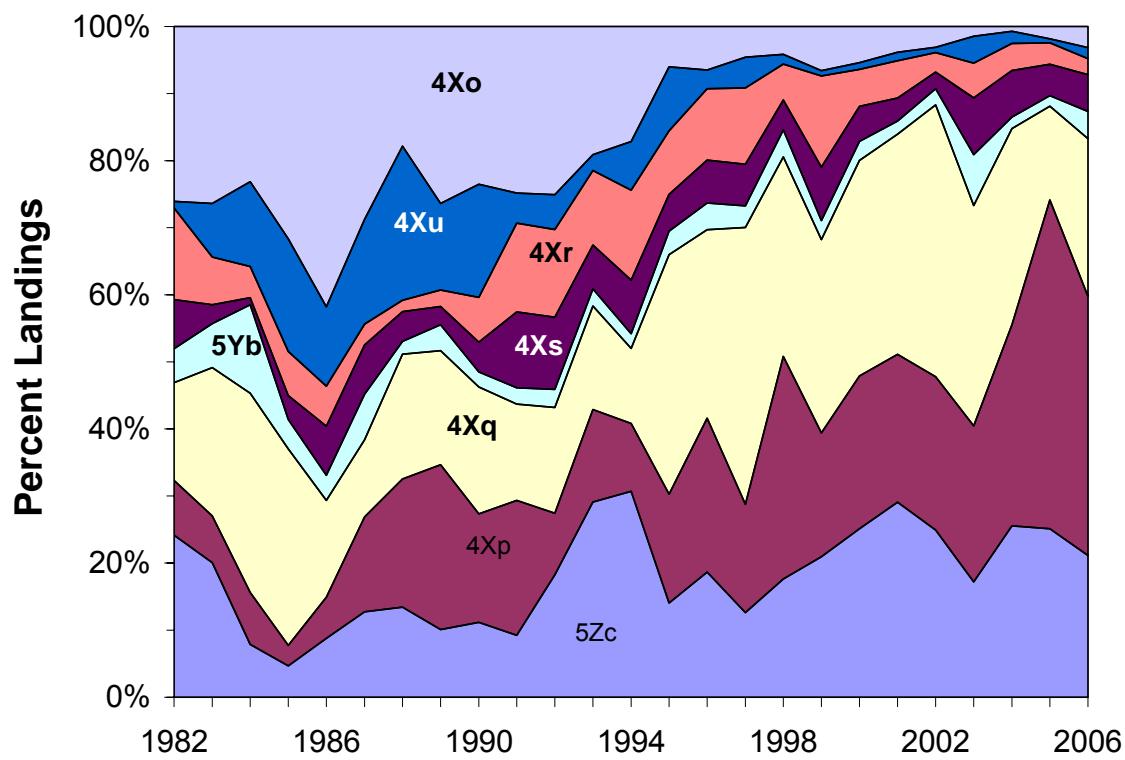

Fig. 4. Proportional landings of pollock by statistical Unit Area from the Western Component, 1982-2006.

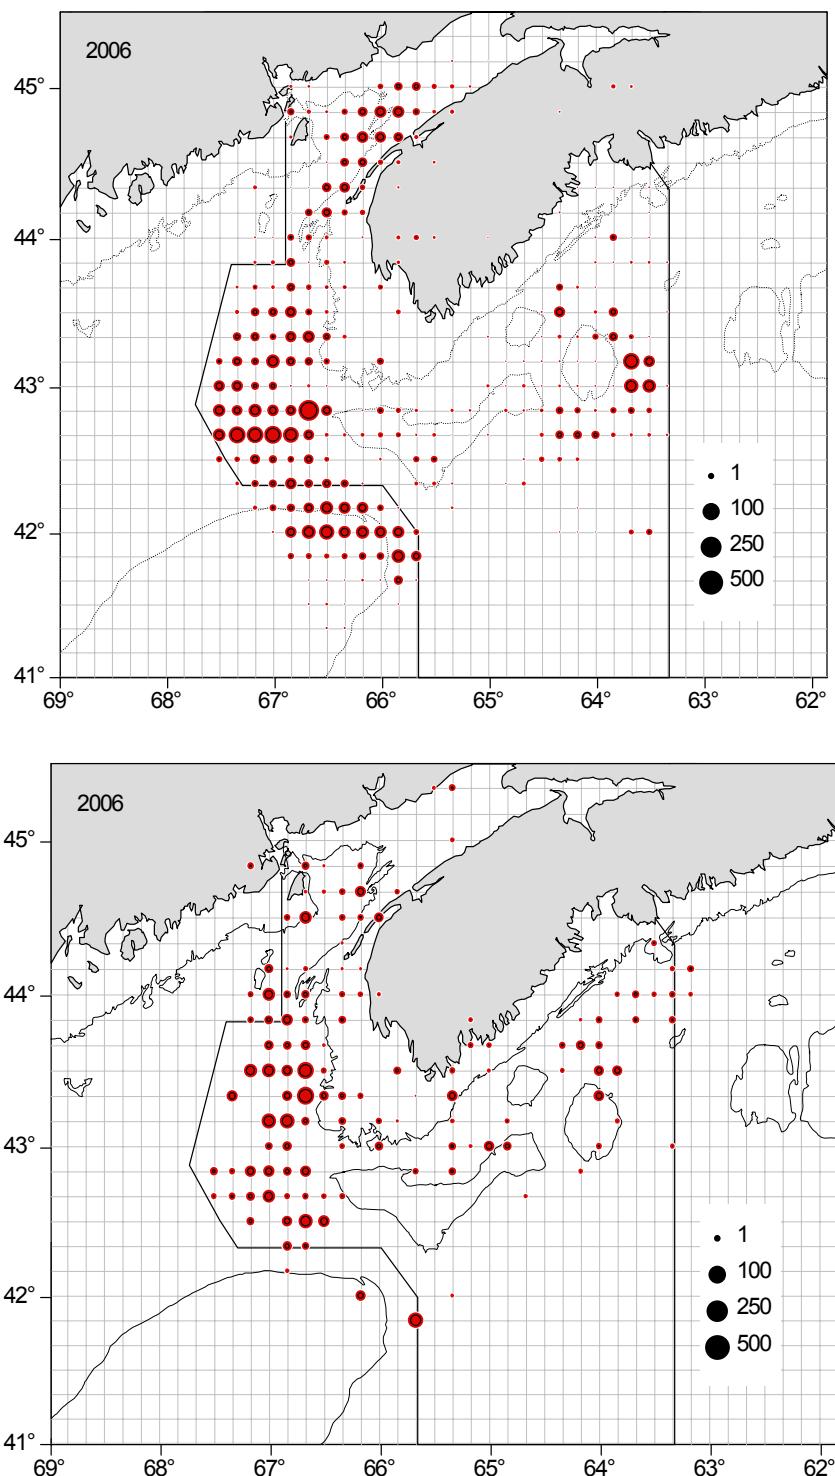

Fig. 5. Spatial distribution of pollock catches for small mobile otter trawl (TC 1-3) (upper panel) and gillnet (lower panel) by 10 minute squares for 2006 (1 Jan - 31 Aug).

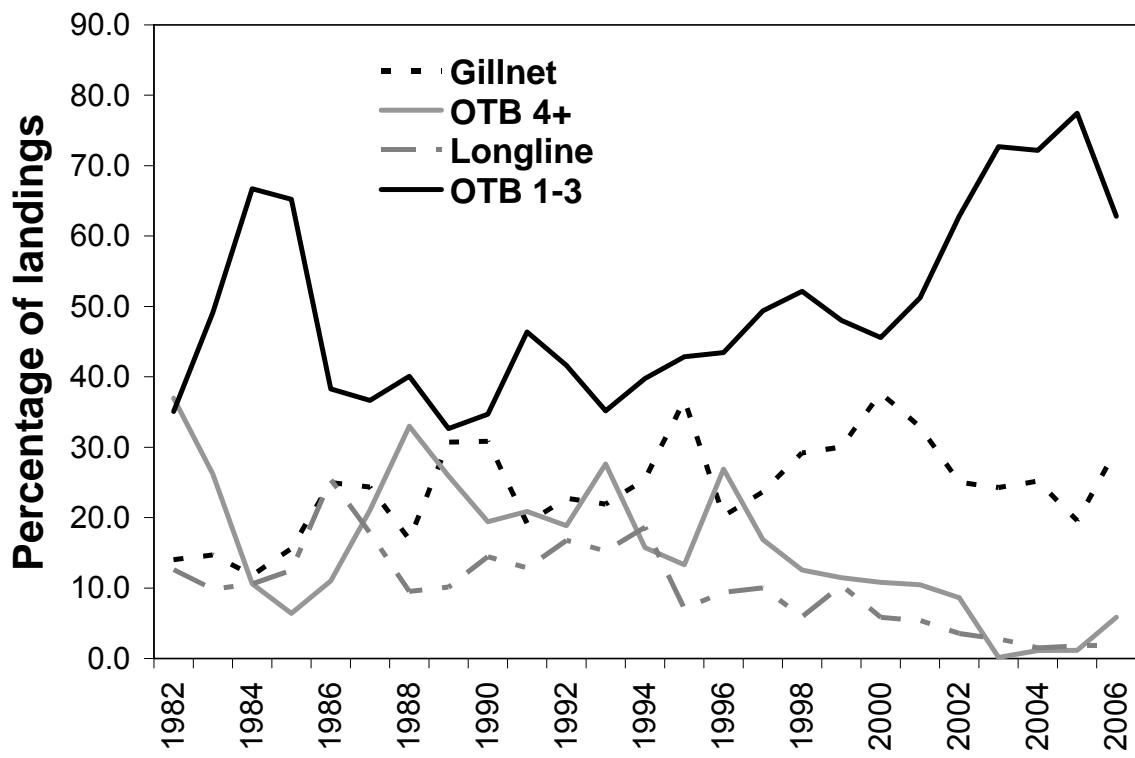

Fig. 6. Proportional landings of pollock by gear type from the Western Component, 1982 -2006.

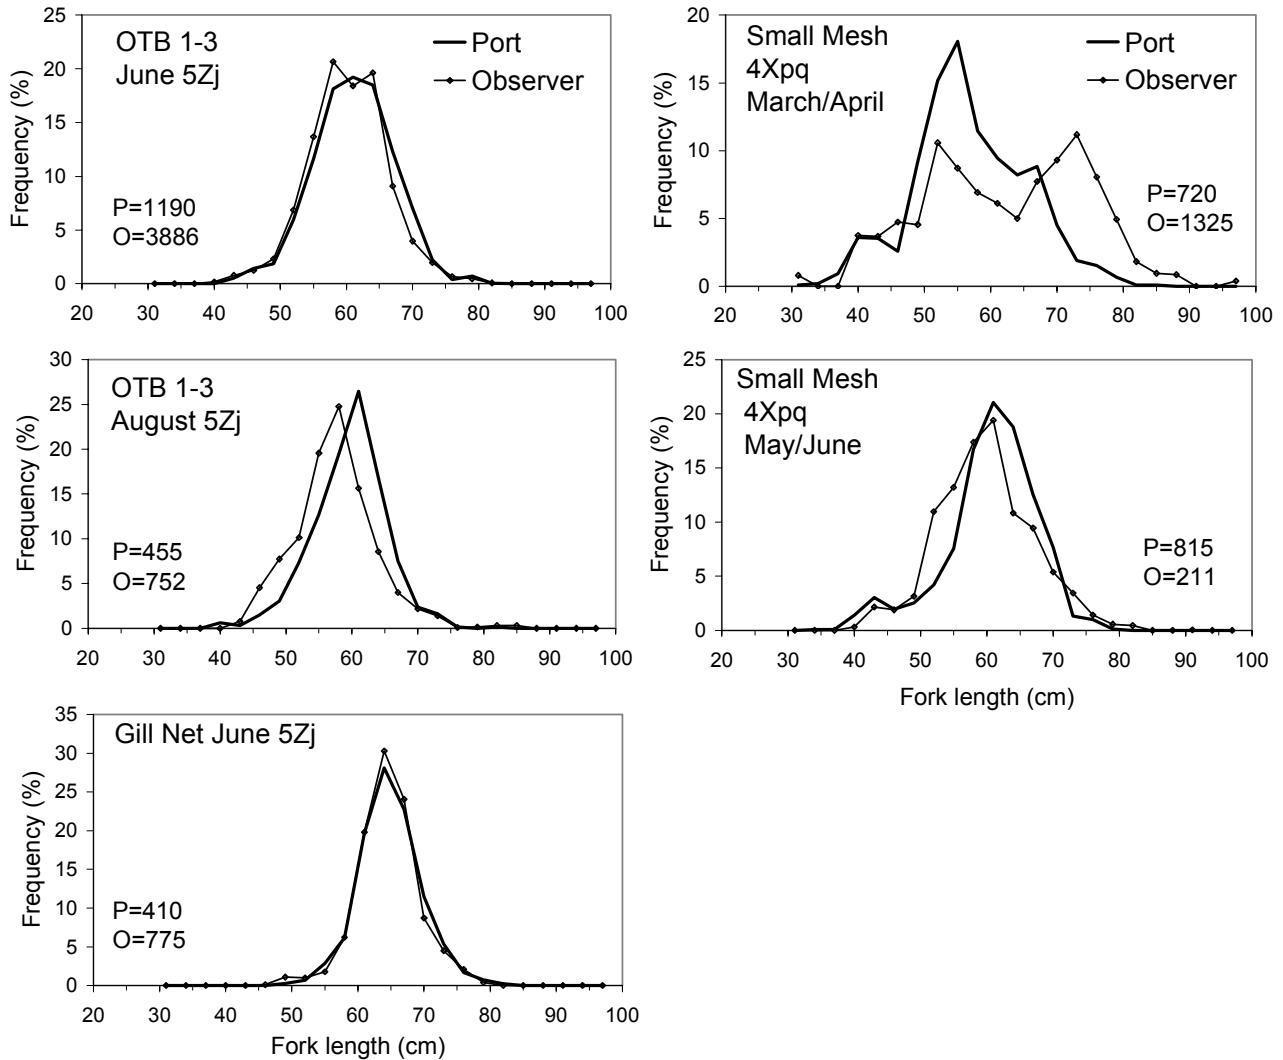

Fig. 7. Comparisons of 2006 port (dockside) and observer (at-sea) sample length measurements of pollock by area, month and gear type from the Western Component. Number of fish measured is shown for port (P) and observer (O) samples.

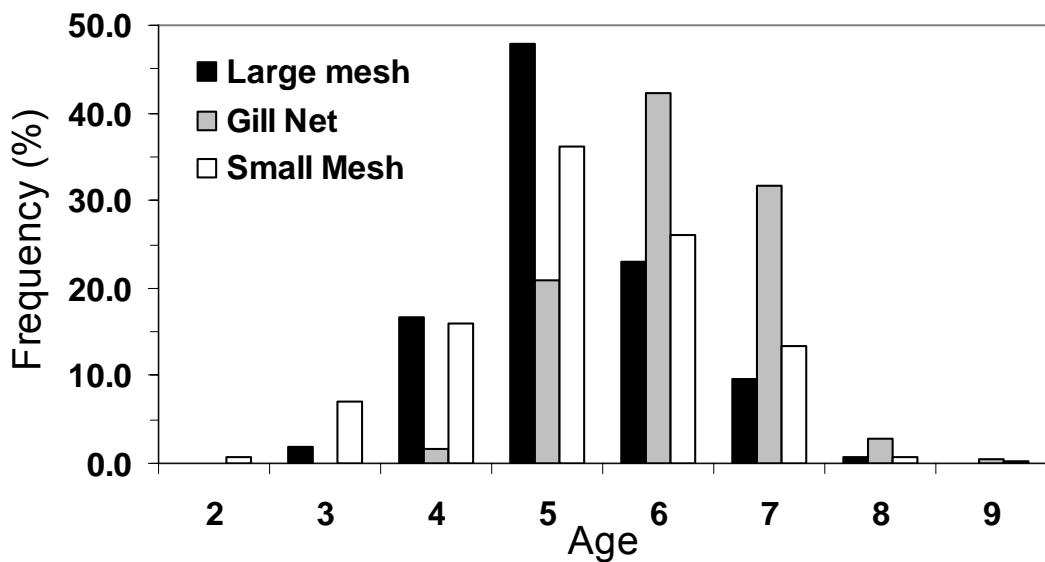

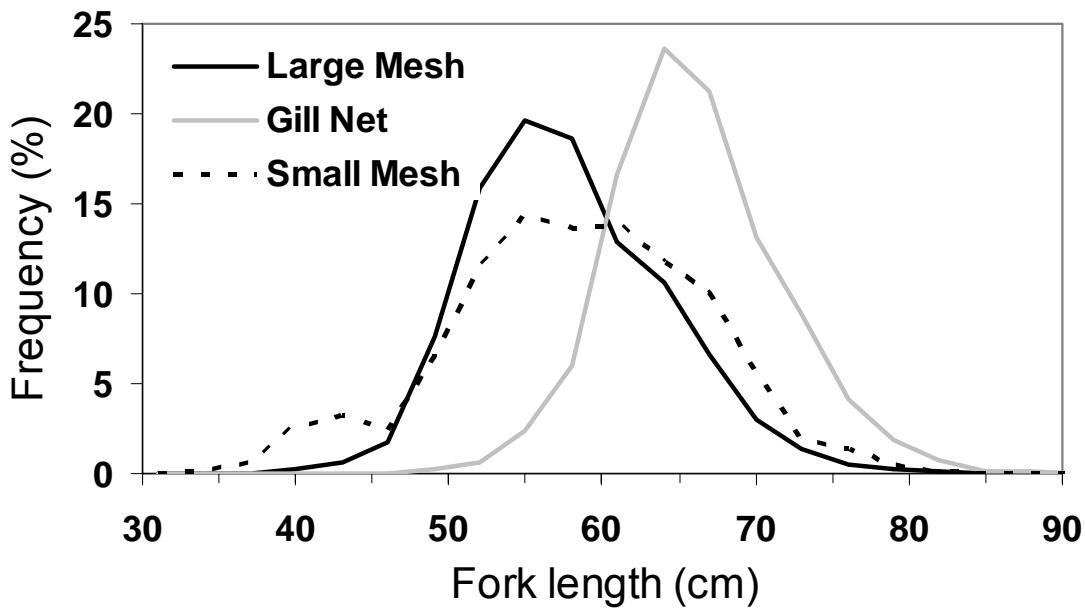

Fig. 8. Catch at size (upper panel) and age (lower panel) of pollock from gill net, large mesh otter trawl (cod end mesh >110mm) and small mesh otter trawl (cod end mesh ≤ 110mm) from the 2006 fishery (Jan. 1 - Aug. 31) in the Western Component area.

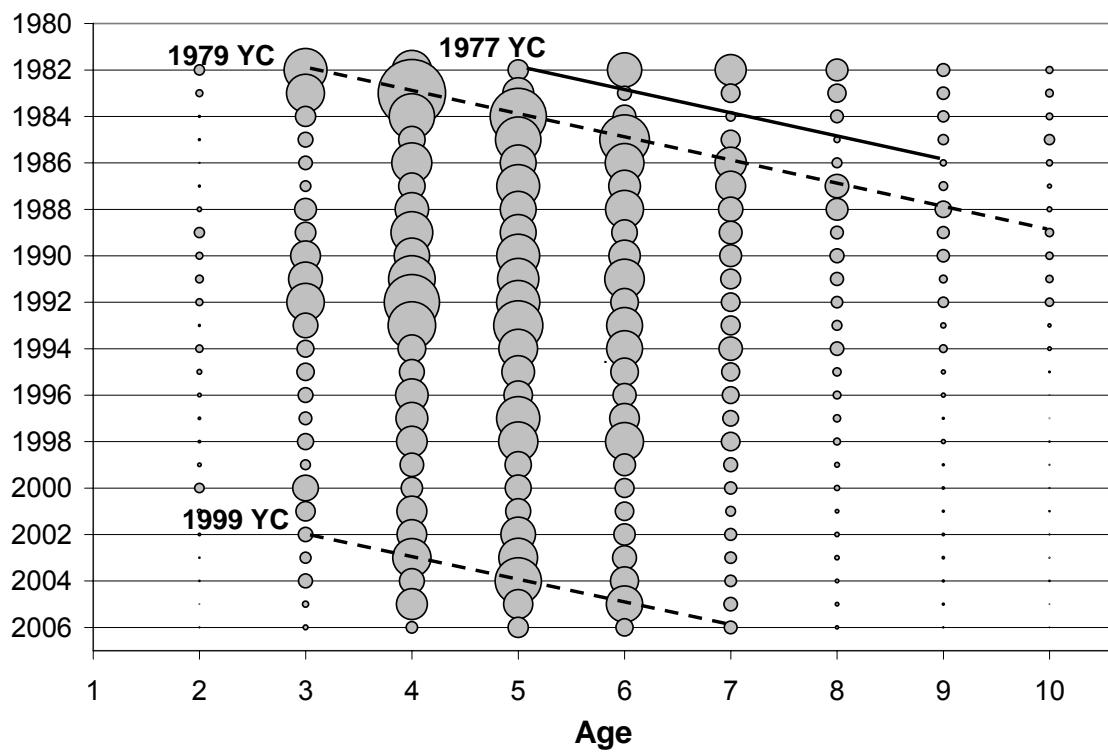

Fig. 9. Catch at age for pollock from the Western Component, 1982-2006. The area of the circle is proportional to the catch at that age and year. Two examples of strong cohorts are highlighted with a dashed line, and a weak cohort is indicated by the solid line.

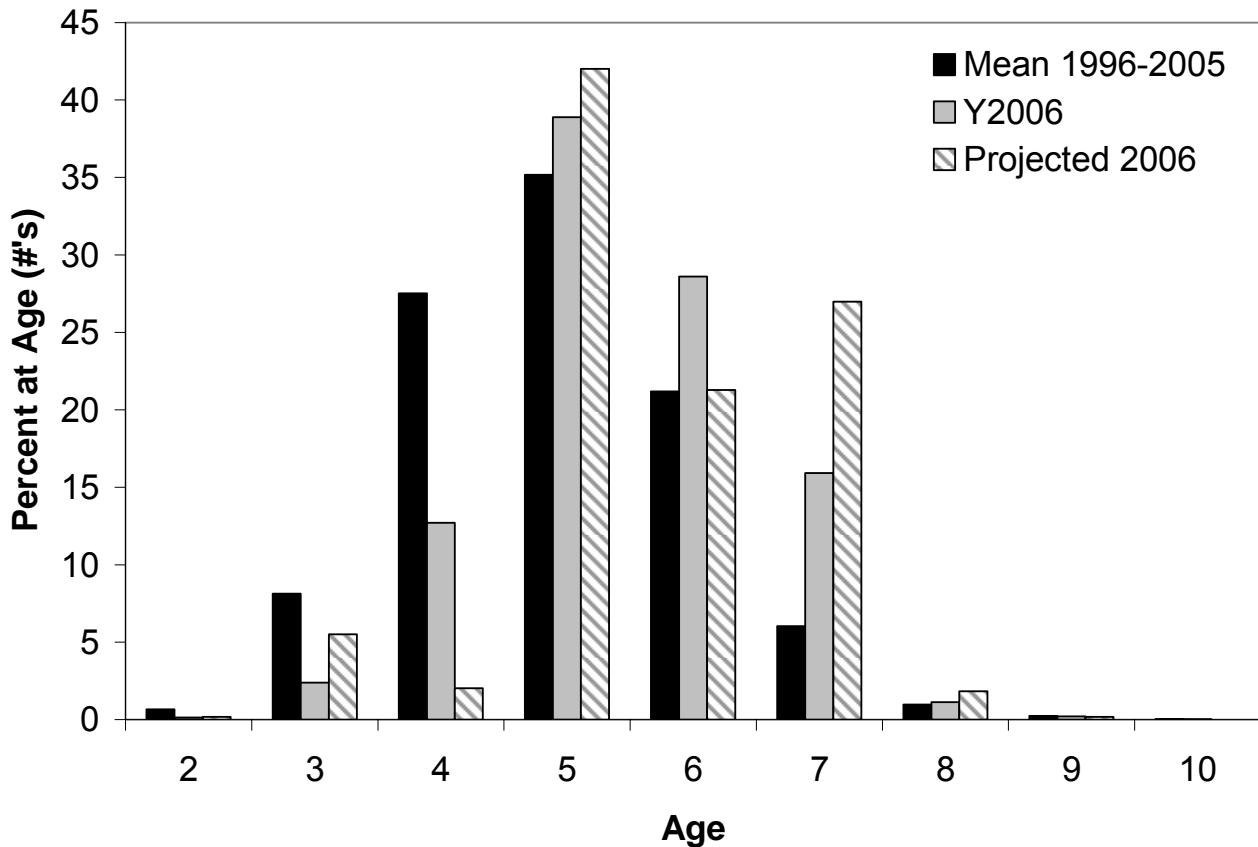

Fig. 10. Age composition of Western Component pollock catch in 2006 compared with the 10 year average from 1996-2005 and the projected catch for 2006 from last years' assessment.

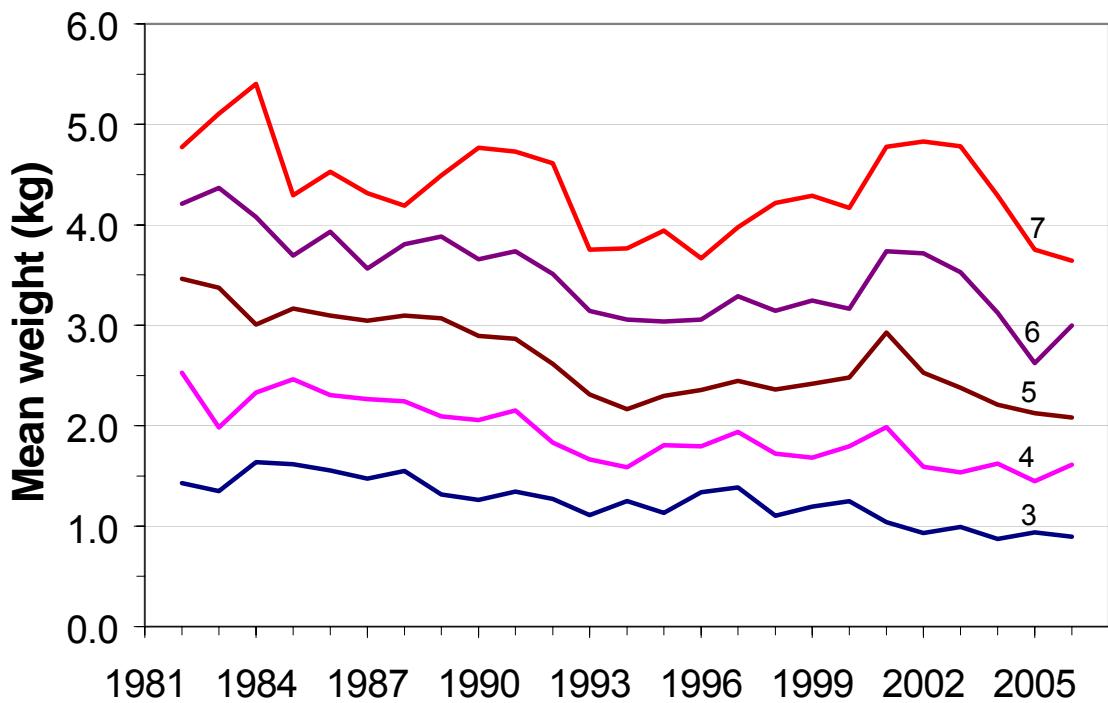

Fig. 11. Trends in fishery weights at age (kg) for pollock aged 3-7 from the Western Component, 1982-2006.

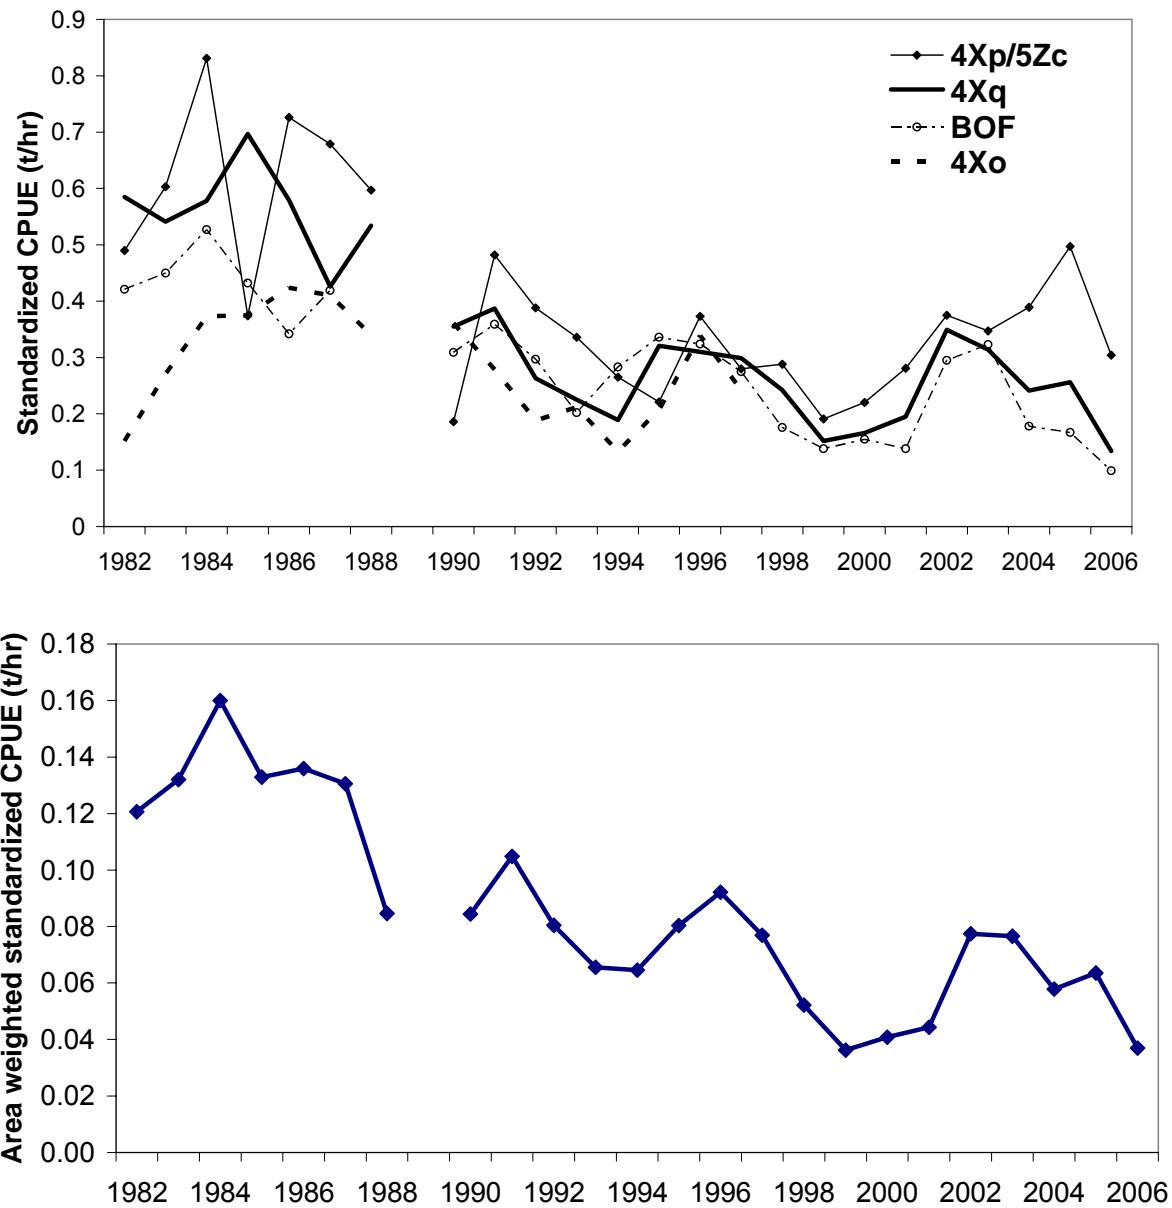

Fig. 12. Standardized mobile gear (OTB 1-3) catch rate series (t/hr) for pollock for the Western Component, 1982-2006. Upper panel: CPUE by area; Lower Panel: area weighted CPUE for combined areas.

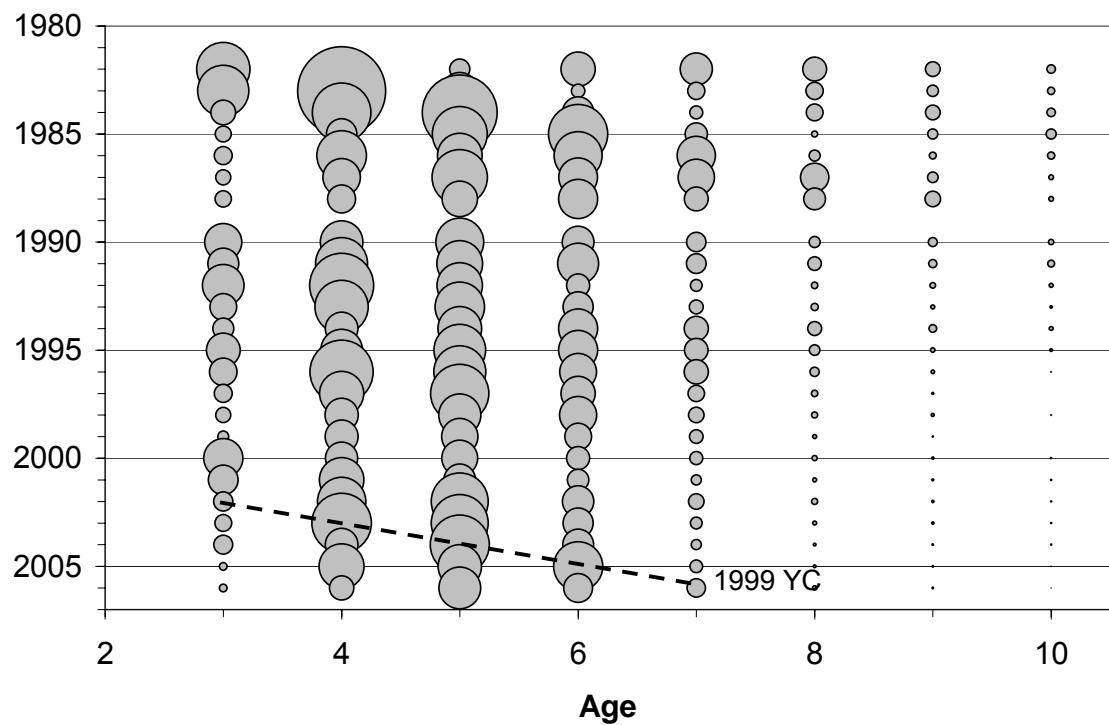

Fig. 13. Age-disaggregated catch rates for small mobile gear operating in the western component, 1982-2006.

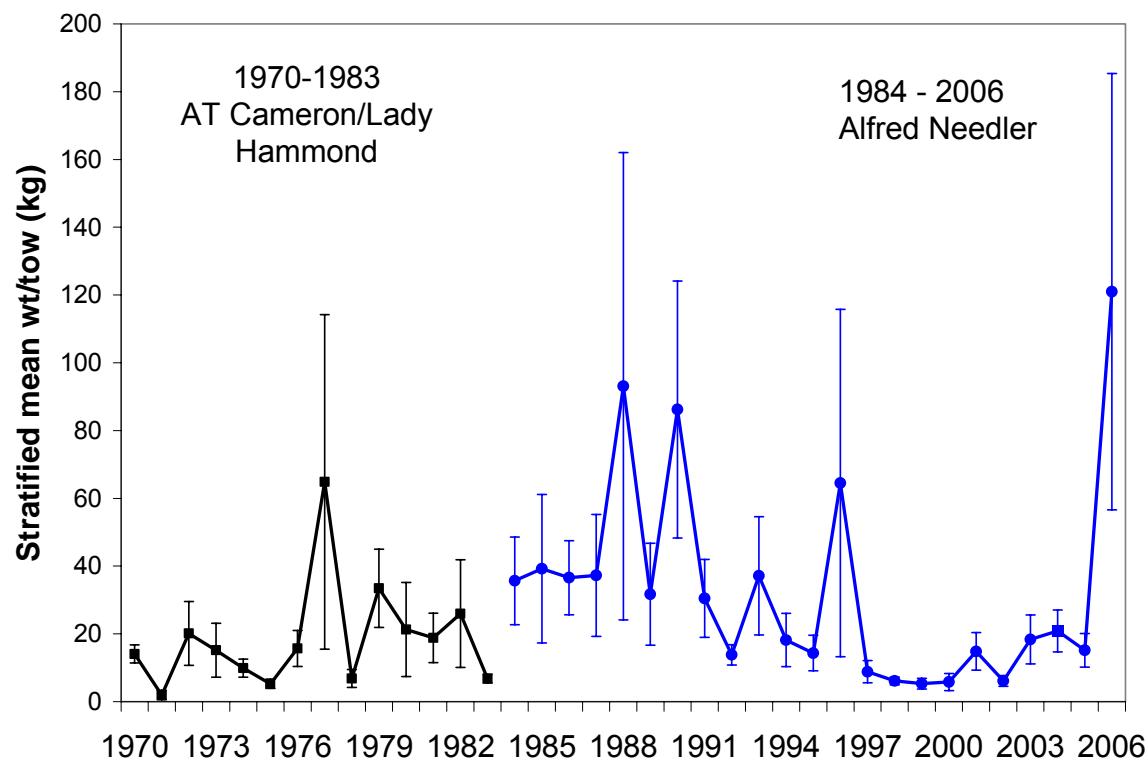

Fig. 14. Stratified mean catch per tow (kg) of pollock from the DFO summer research vessel survey in 4X strata (strata 474, 476 and 480-495) corresponding to the Western Component, 1970-2006. Data from 1984 until the present is the input data used in the VPA.

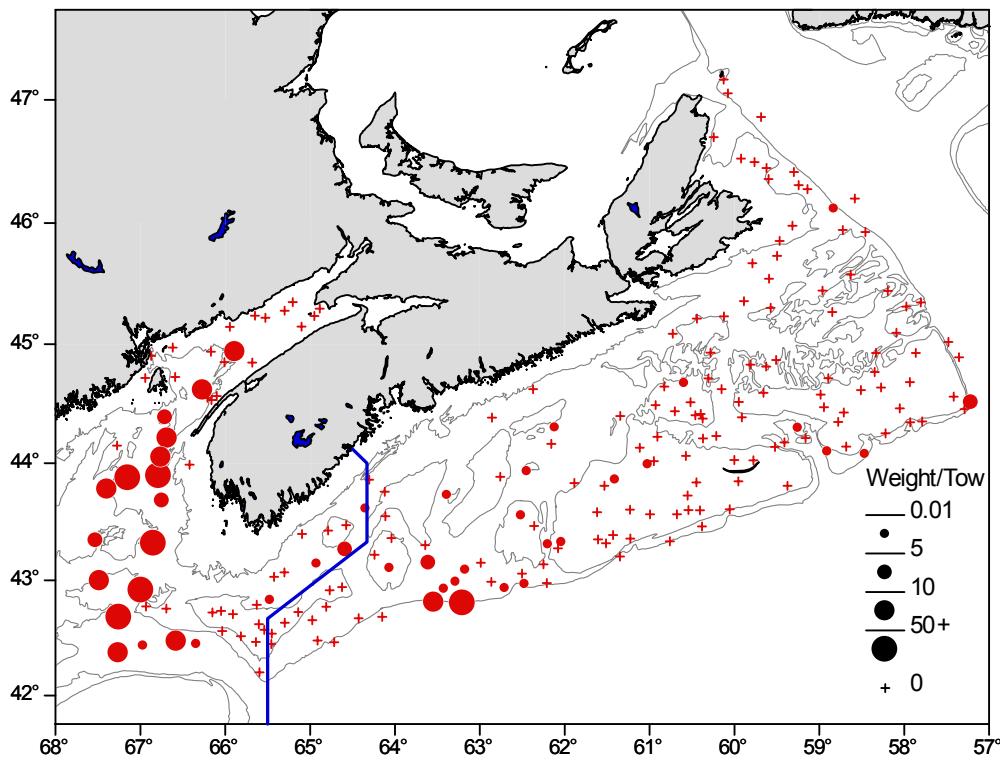

Fig. 15. Pollock biomass distribution (kg/tow) from the 2006 DFO summer survey. The solid line separates the Eastern and Western Components.

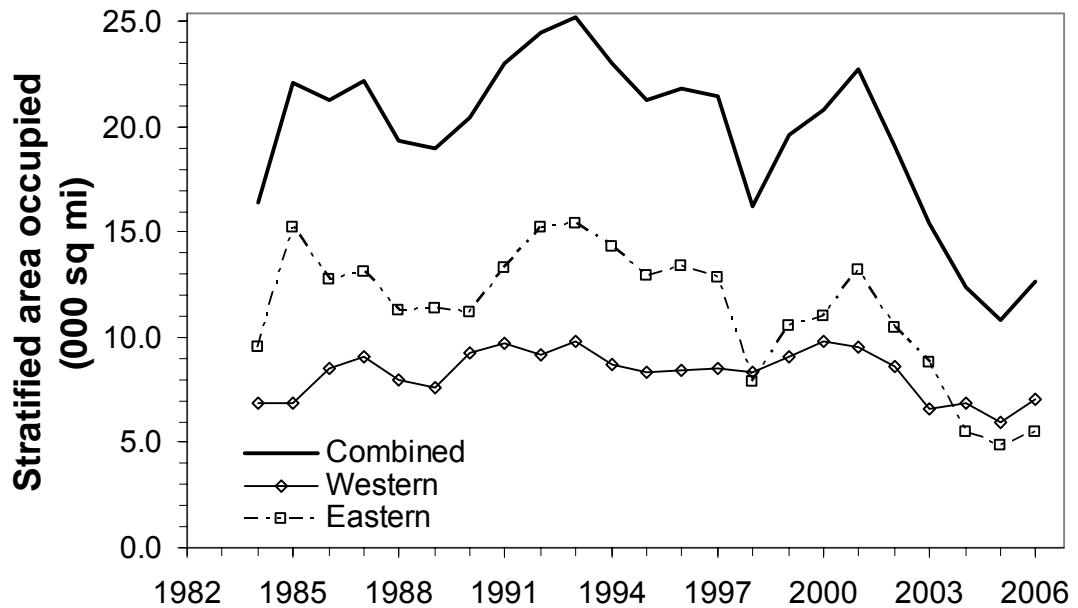

Fig.16. Stratified area occupied (000s sq mi) by pollock in the Eastern and Western component strata from the DFO summer RV survey, 1984-2006.

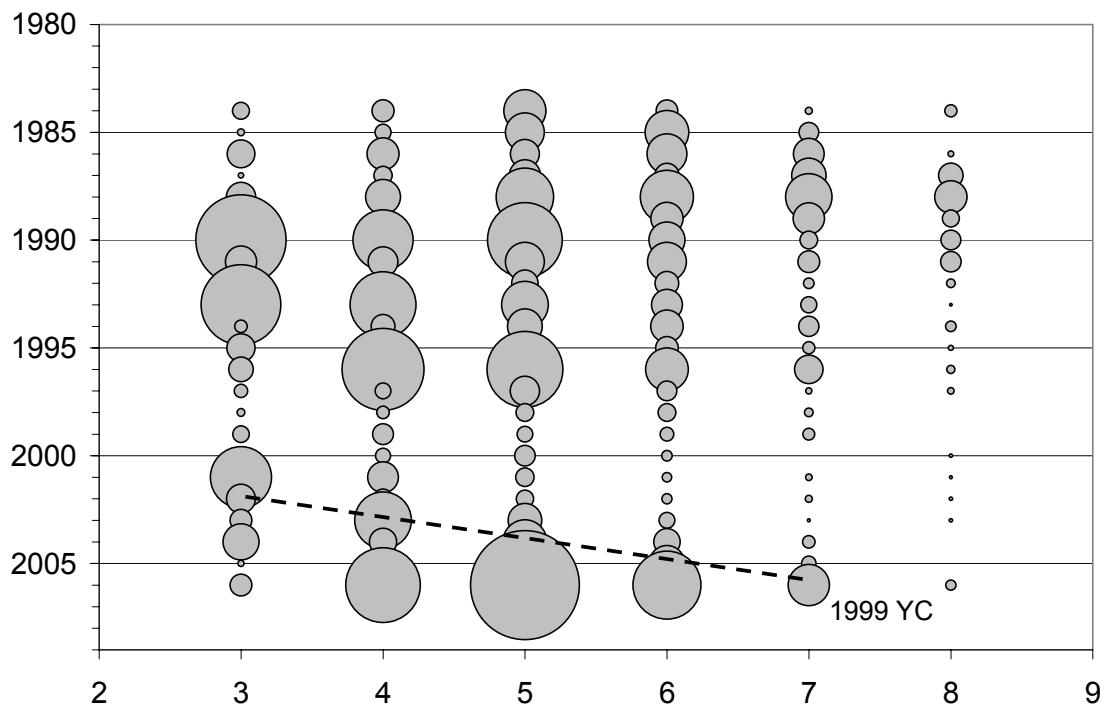

Fig. 17. Stratified mean number per tow at age of pollock from the DFO summer research vessel survey in 4X strata corresponding to the Western Component, 1984-2006.

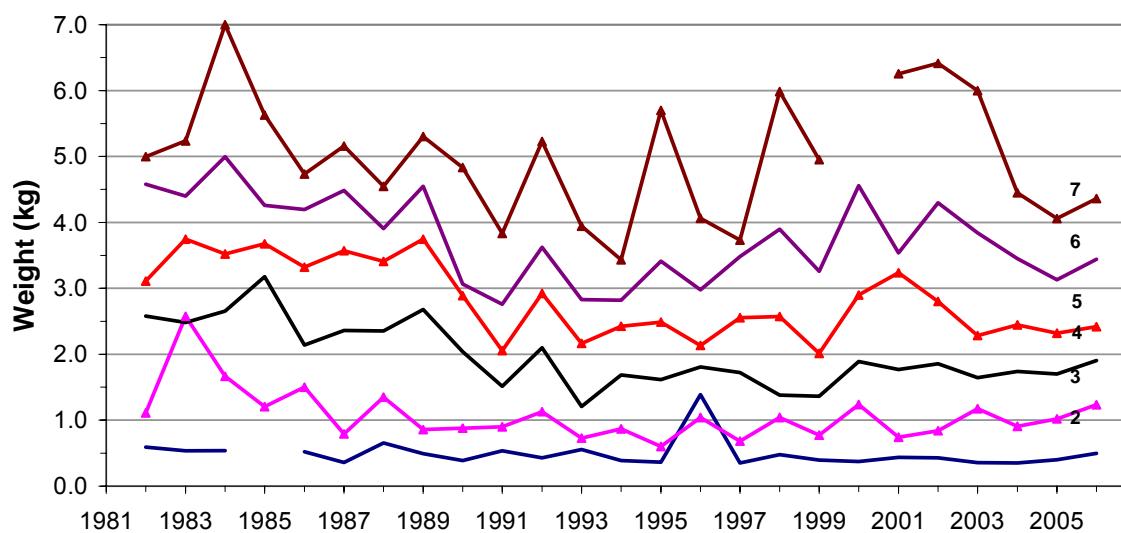

Fig. 18. Weight at age for pollock ages 2-7 from the DFO summer research vessel survey in 4X strata corresponding to the Western Component, 1982-2006.

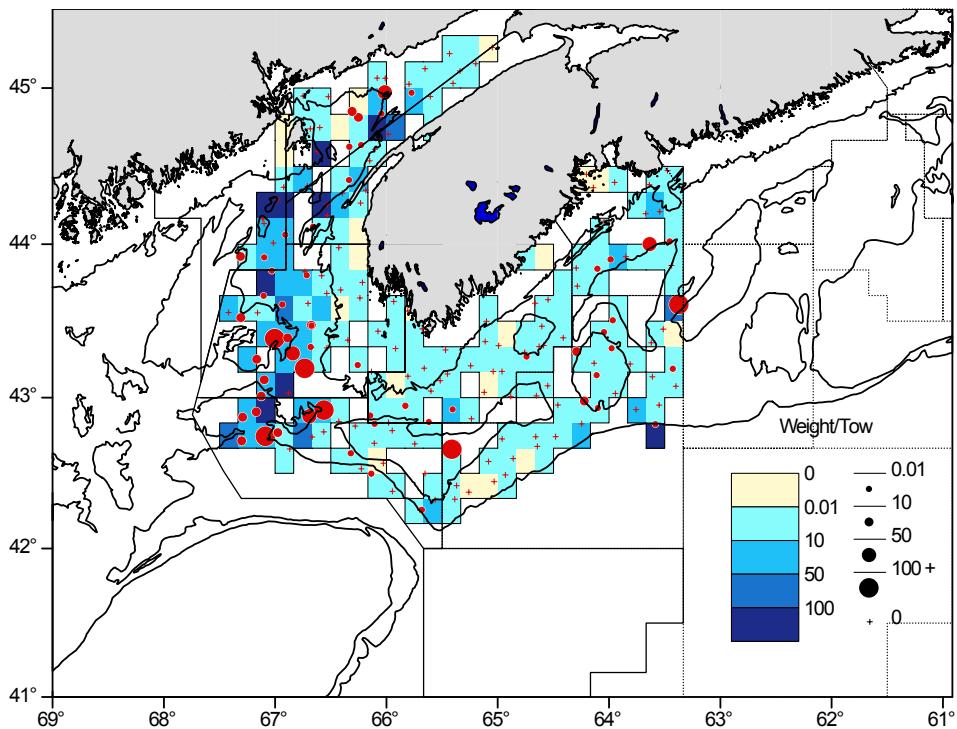

Fig. 19. ITQ survey pollock biomass (kg/tow) distribution for 2006 (solid circles), shown with respect to the average catch over the past ten years (shaded rectangles).

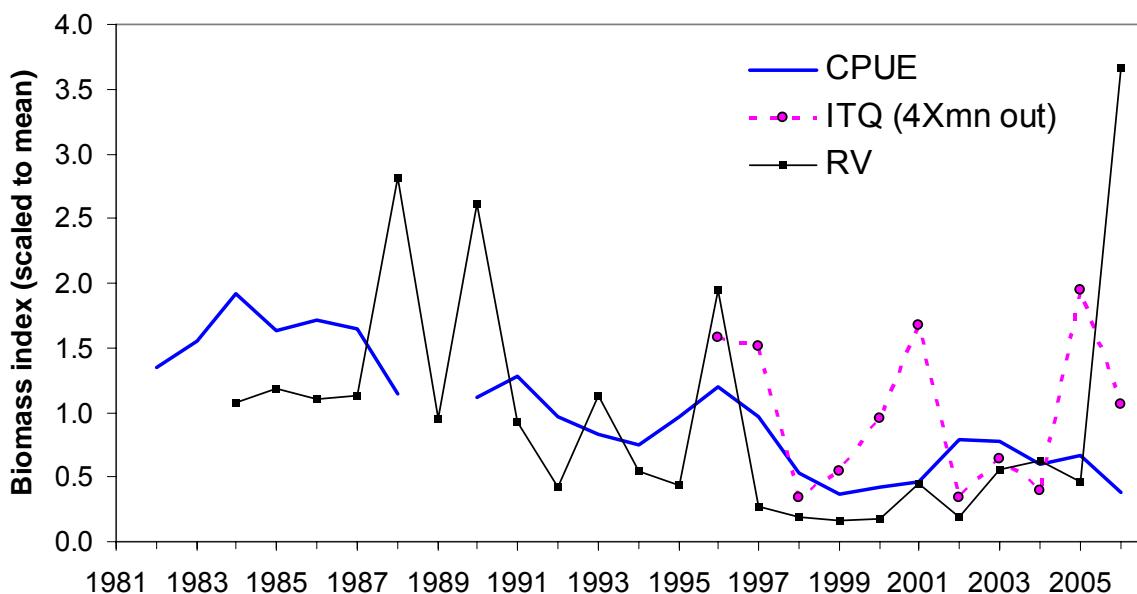

Fig. 20. Trends in pollock biomass indices from the mobile gear CPUE series (1982-2006), DFO research vessel survey (1984-2006) and the ITQ survey (1996-2006) for the Western Component area.

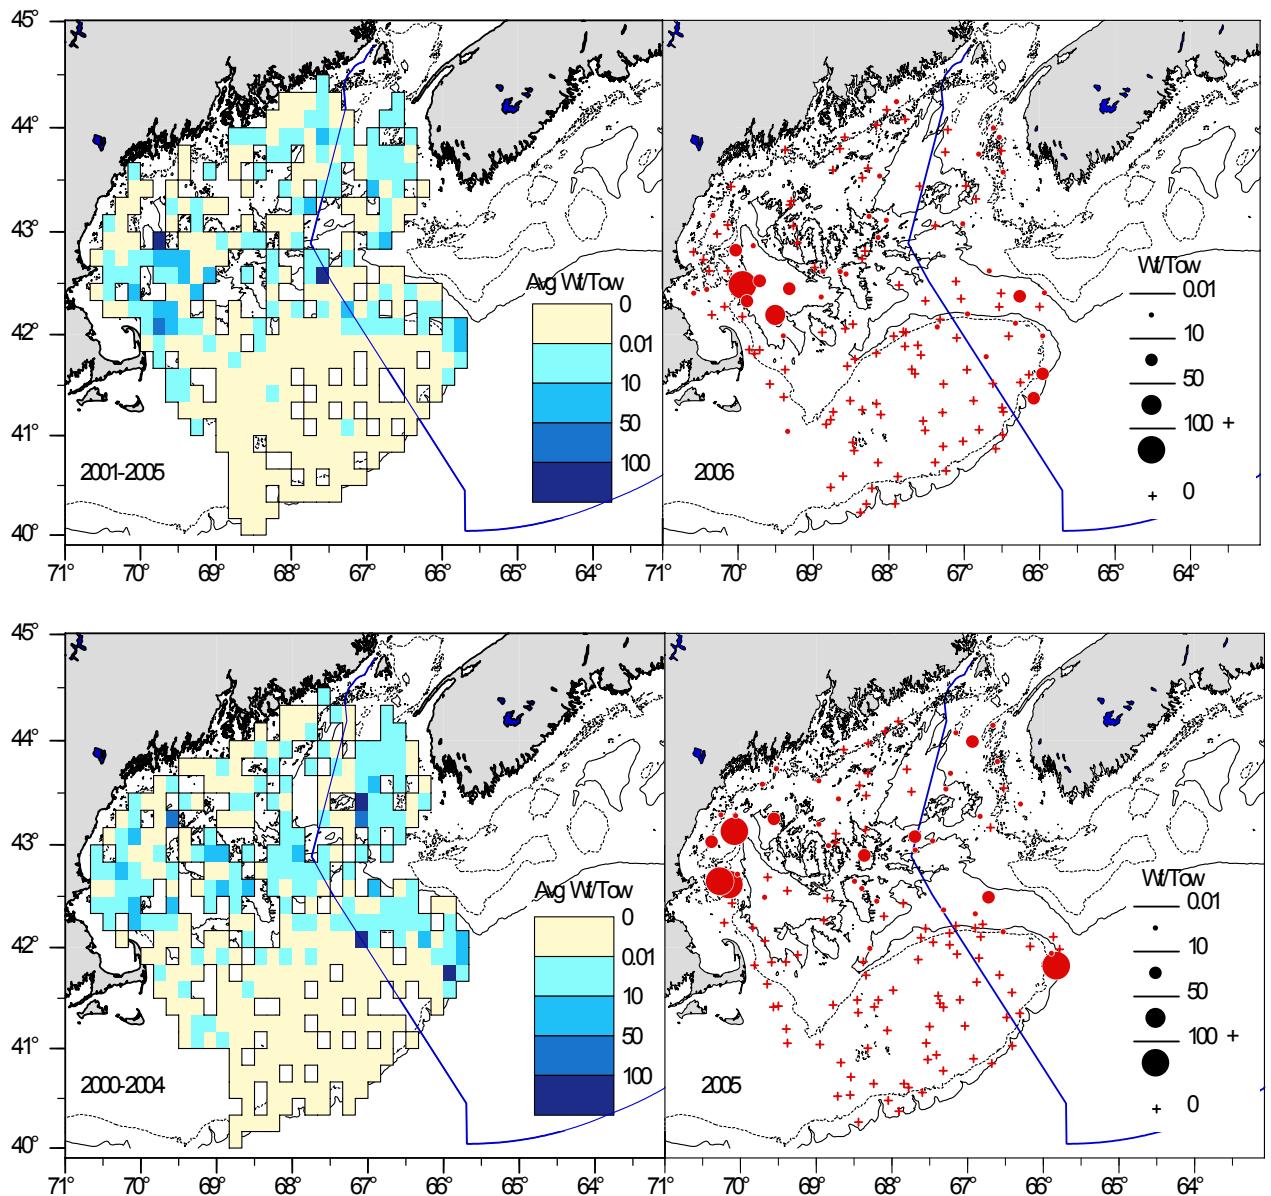

Fig. 21. National Marine Fisheries Service (NMFS) bottom trawl survey biomass distribution (kg/tow) for spring (upper panel) and fall (lower panel) surveys conducted in 2006 and 2005, respectively (solid circles) compared with the average for the previous five years (shaded rectangles). The solid line indicates the International Boundary.

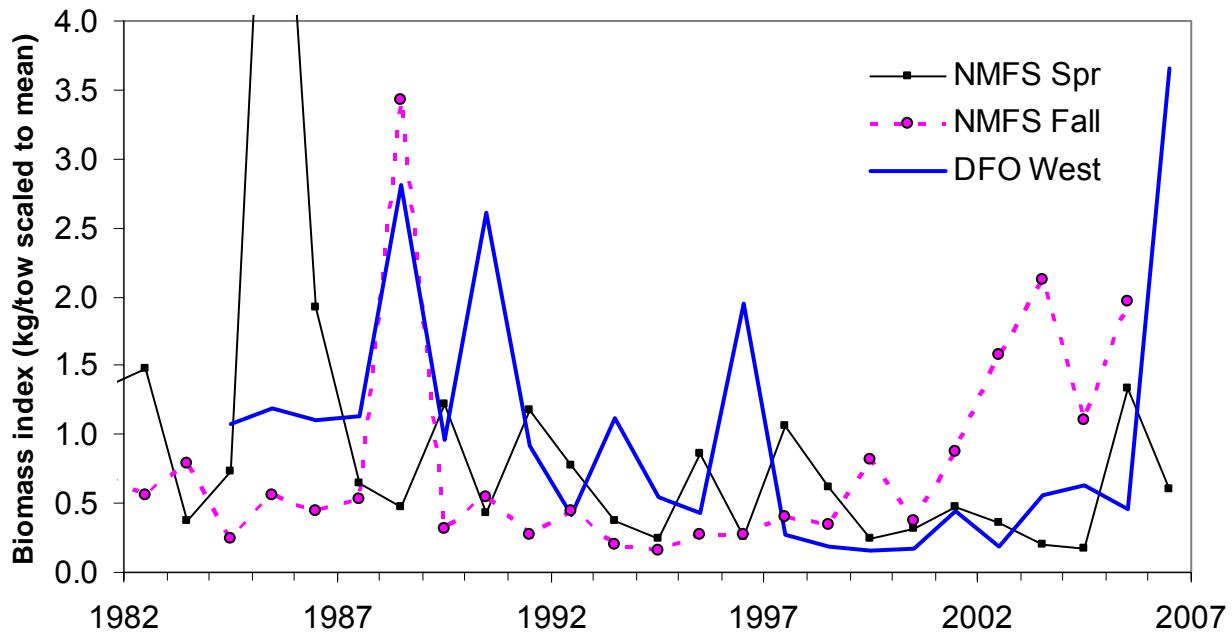

Fig. 22. Comparison of biomass indices (kg/tow, scaled to mean of series) from the NMFS Spring, NMFS Fall and DFO RV surveys.

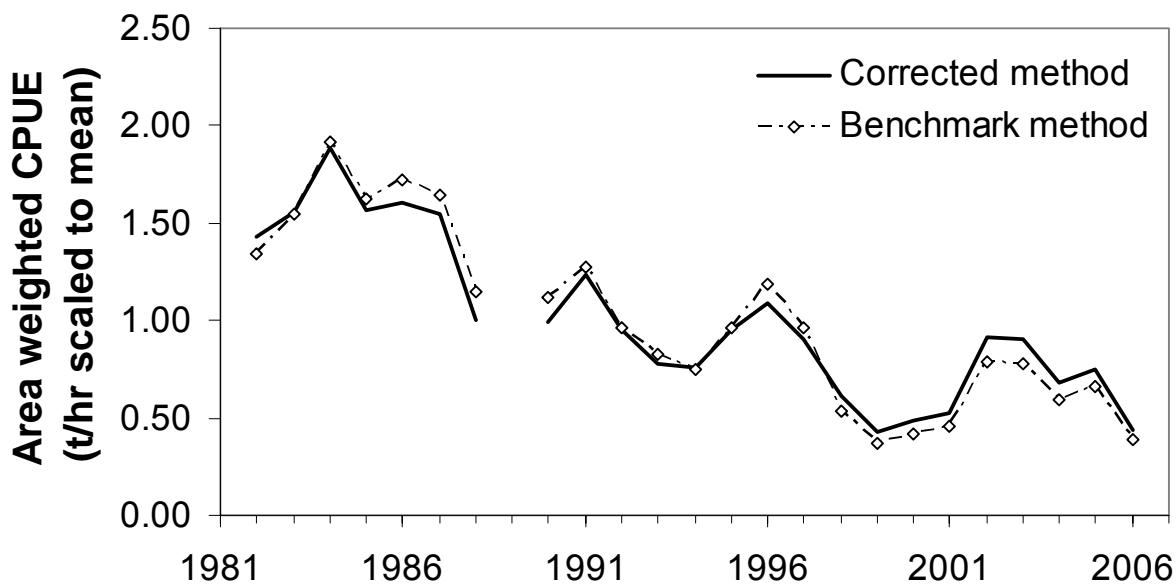

Fig. 23. Comparison area combined CPUE calculated using the Benchmark method (by dividing) and the corrected method (by multiplying) for applying the weighting factor to area specific standardized CPUE series.

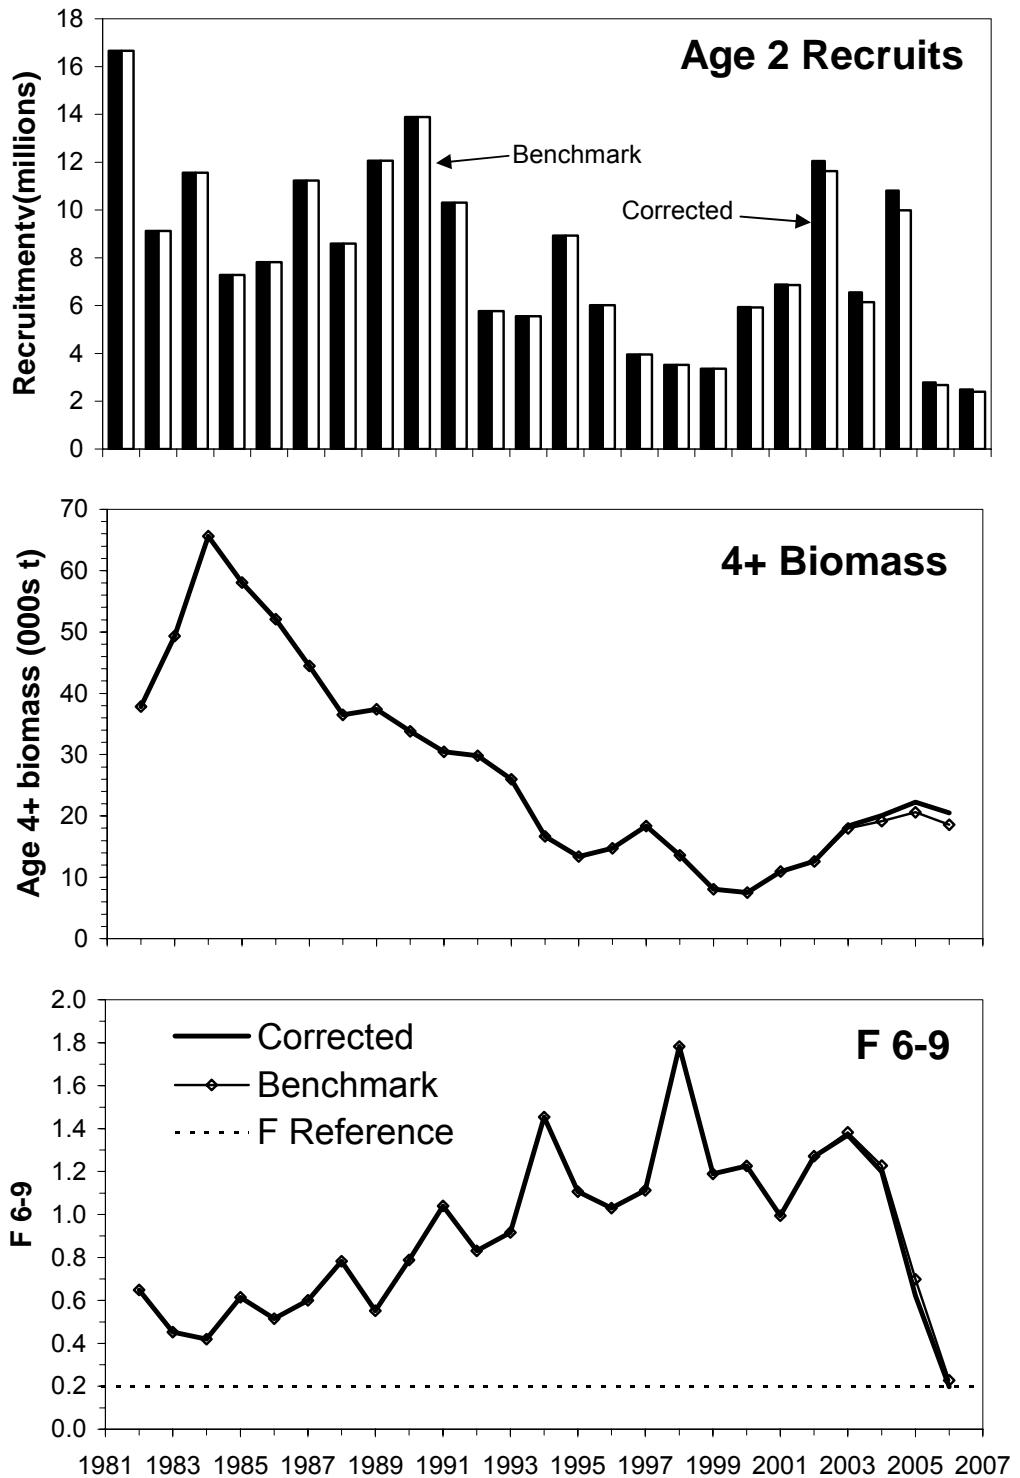

Fig. 24. Comparison area combined CPUE calculated using the Benchmark method (by dividing) and the corrected method (by multiplying) for applying the weighting factor to area specific standardized CPUE series.

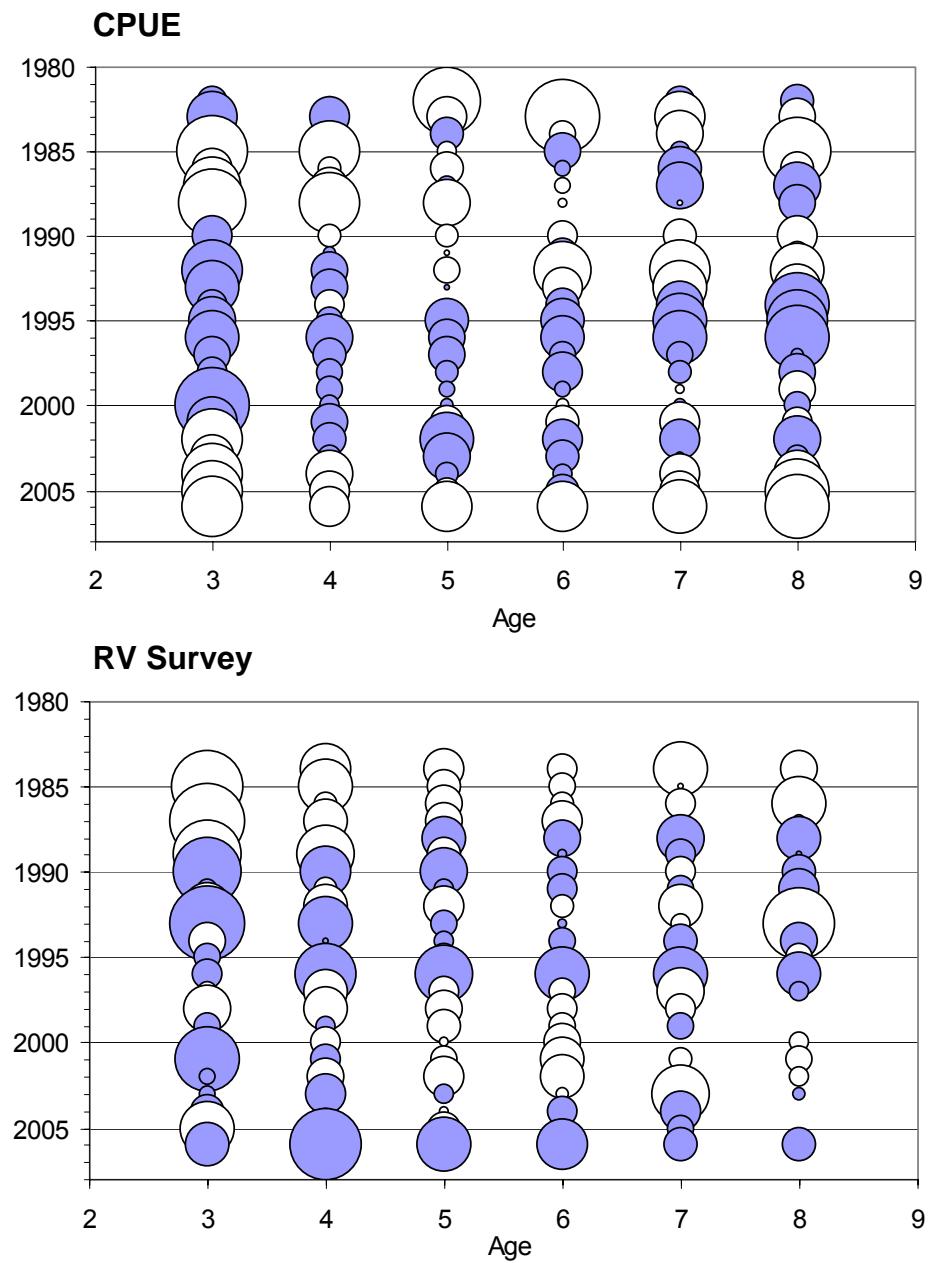

Fig. 25. Age-specific residuals for the Base VPA formulation, Western Component pollock, for the relationships between \ln abundance index versus \ln population numbers for the CPUE series (upper panel) and the RV series (lower panel). Closed circles denote positive residuals and open circles denote negative residuals. (Bubble size is proportional to magnitude).

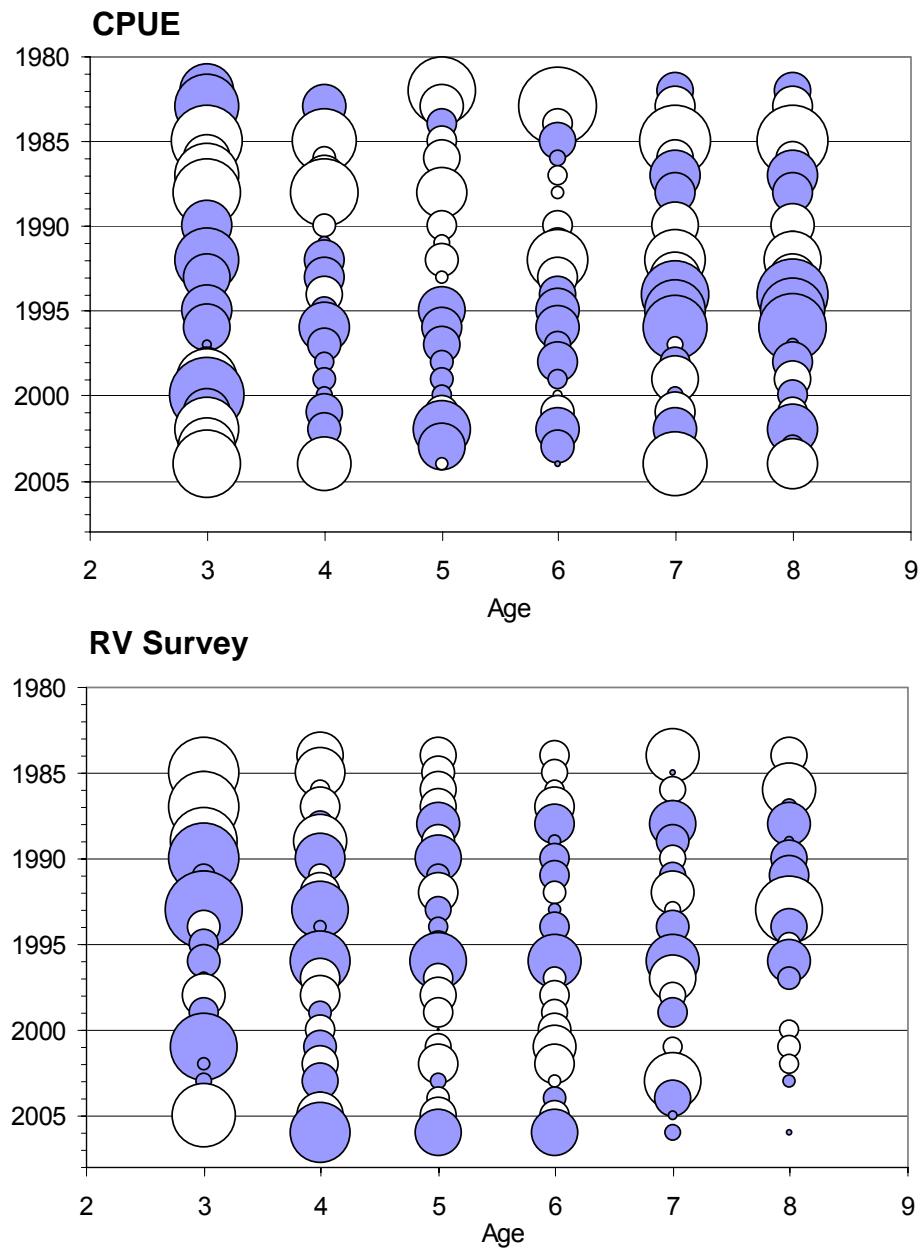

Fig. 26. Age-specific residuals for the Modified Base VPA formulation, Western Component pollock, for the relationships between \ln abundance index versus \ln population numbers for the CPUE series (upper panel) and the RV series (lower panel). Closed circles denote positive residuals and open circles denote negative residuals. (Bubble size is proportional to magnitude).

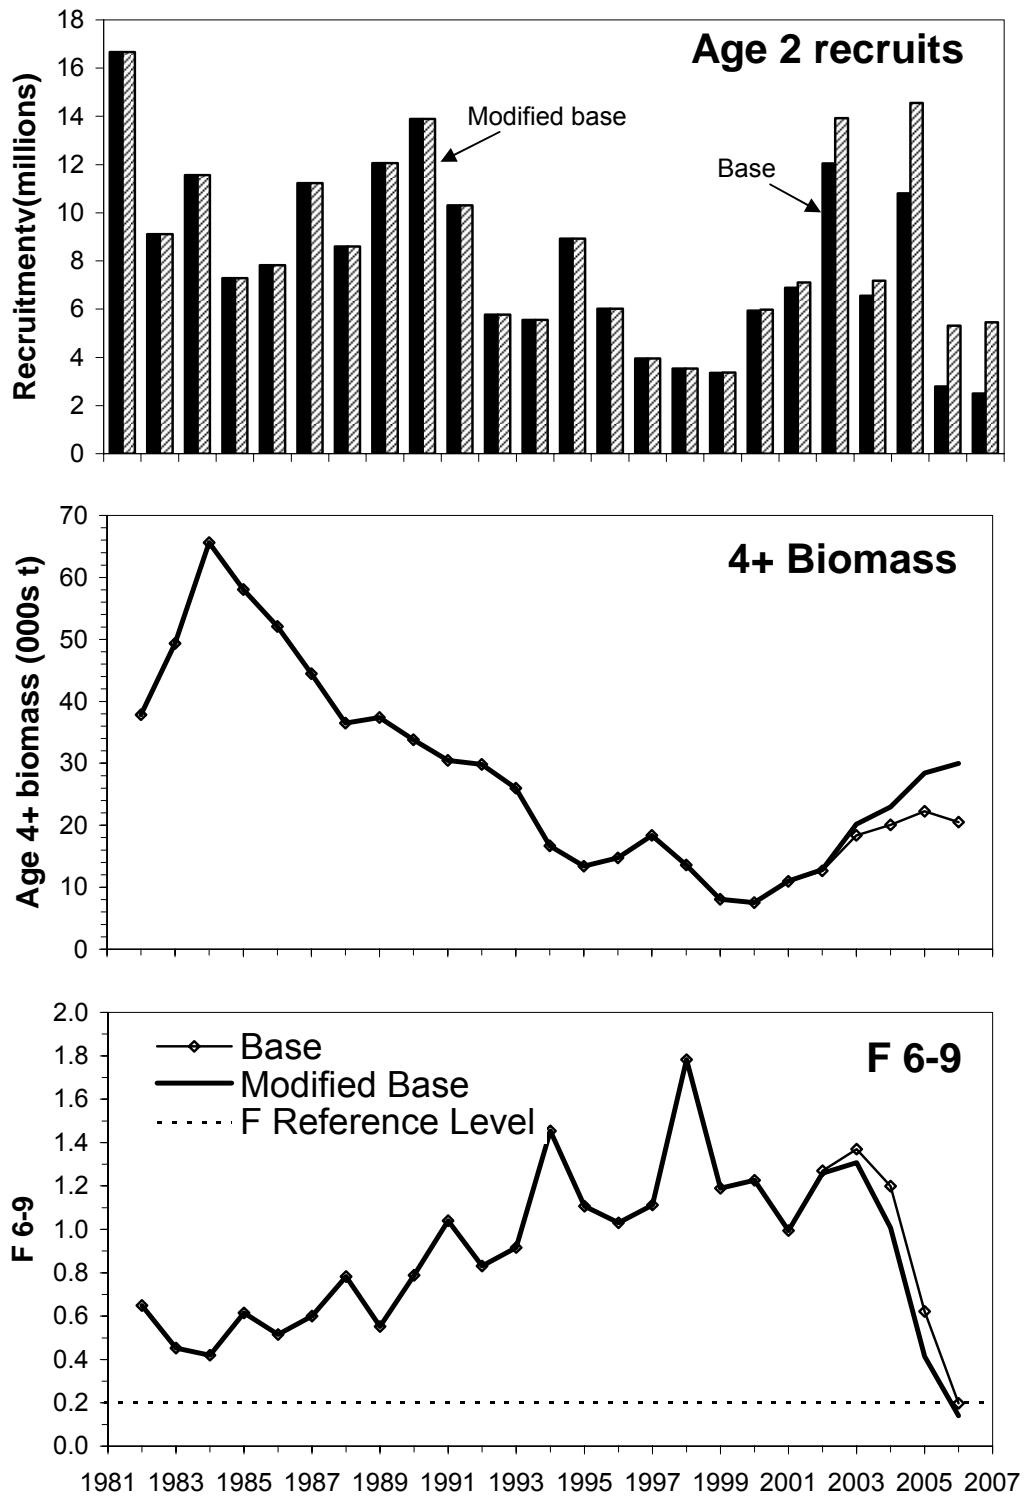

Fig. 27. Comparison of trends in age 2 recruitment, 4+ biomass and age 6-9 fishing mortality for the Western Component from the Base VPA and the Modified Base VPA with 2005 and 2006 removed from the CPUE series.

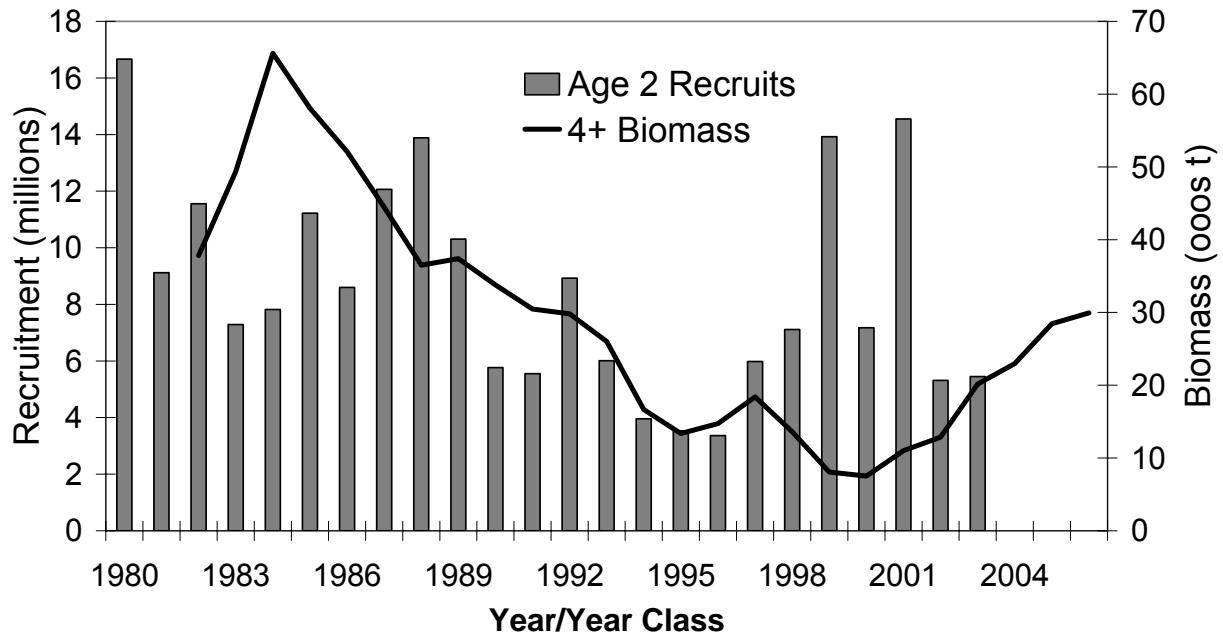

Fig. 28. Trends in age 4+ biomass and age 2 recruitment of pollock in the Western Component from the Modified Base VPA formulation.

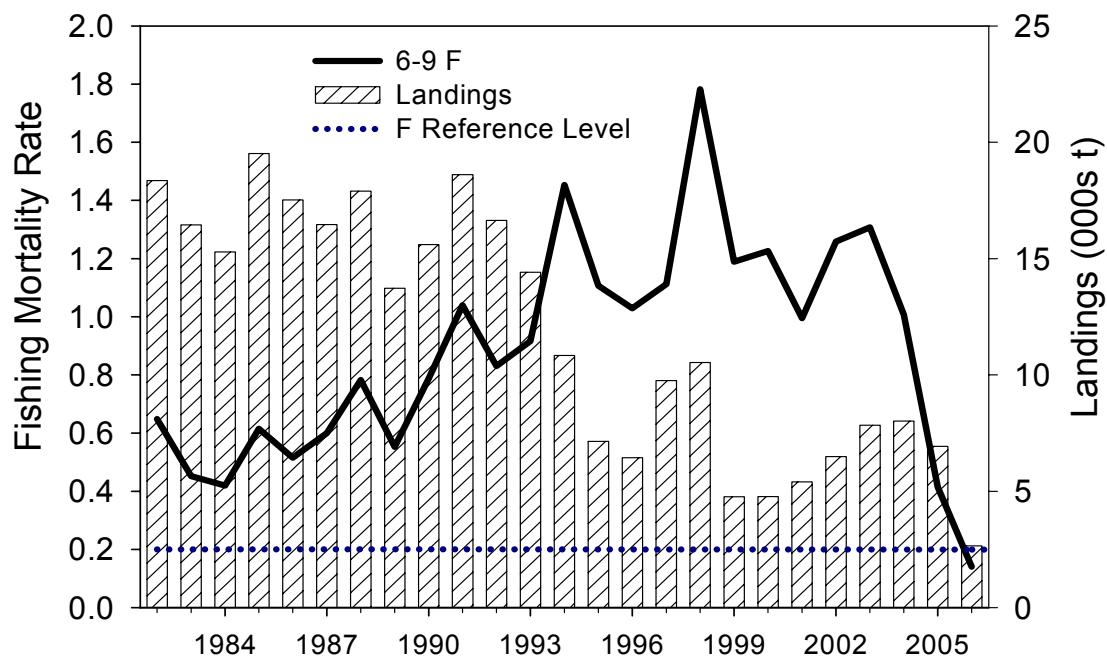

Fig. 29. Trends in fishing mortality and landings of pollock for the Western Component from the Modified Base VPA formulation.

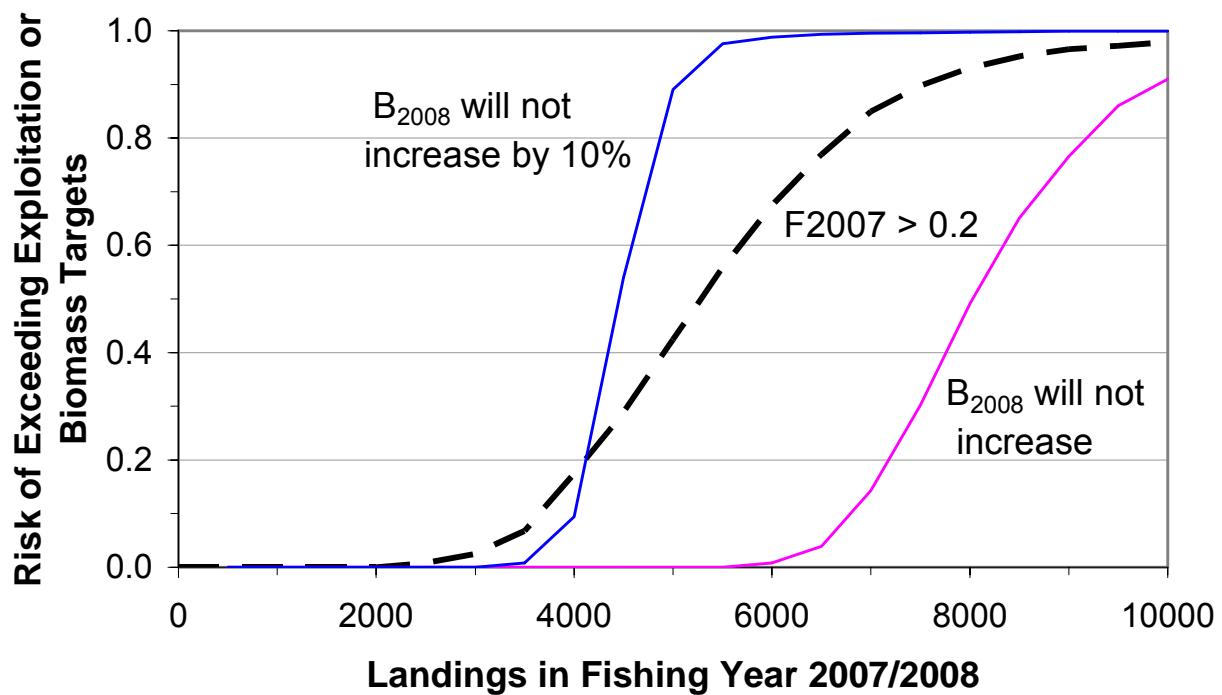

Fig. 30. Risk of exceeding exploitation or biomass rebuilding targets for Western Component from the Modified Base VPA formulation.

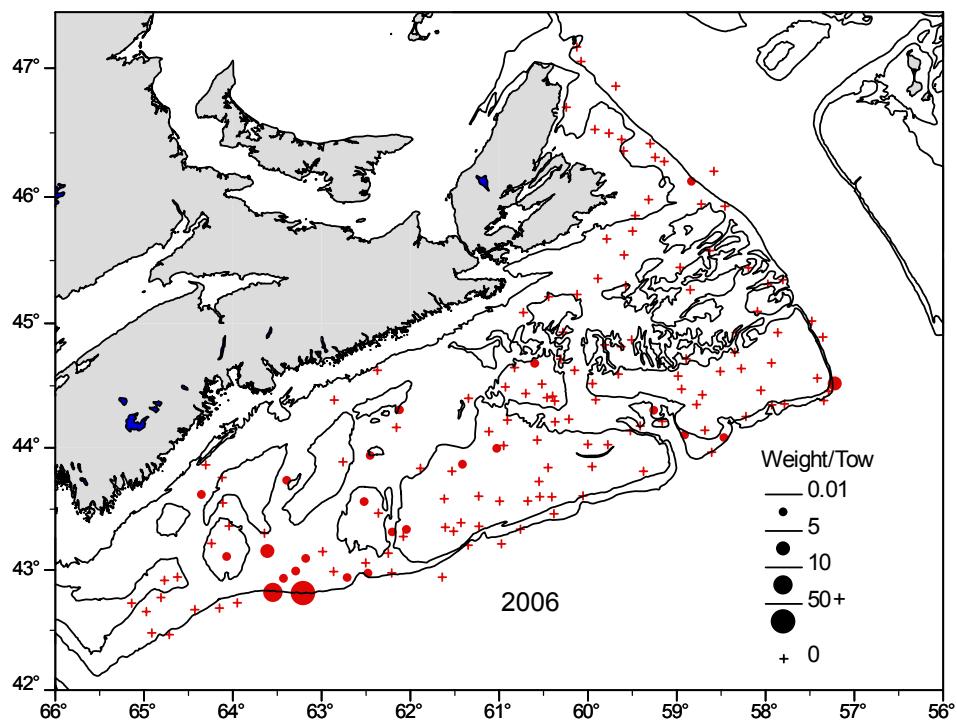

Fig. 31. Spatial distribution of pollock catches during the 2006 RV survey in the Eastern Component.

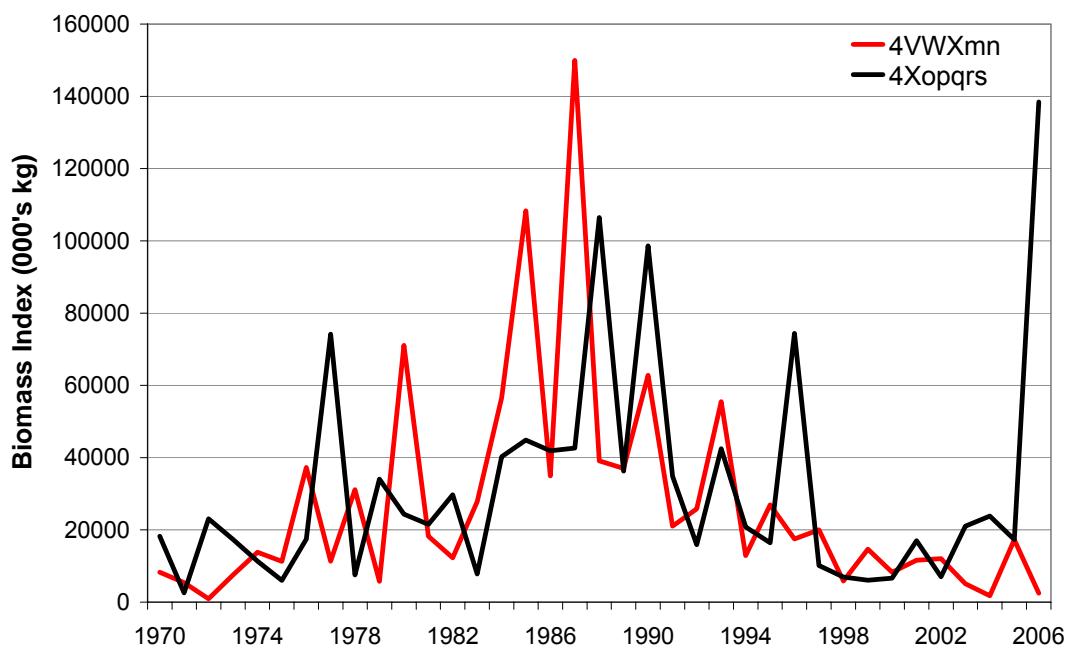

Fig. 32. RV survey biomass indices from the Eastern and Western components, 1970-2006.

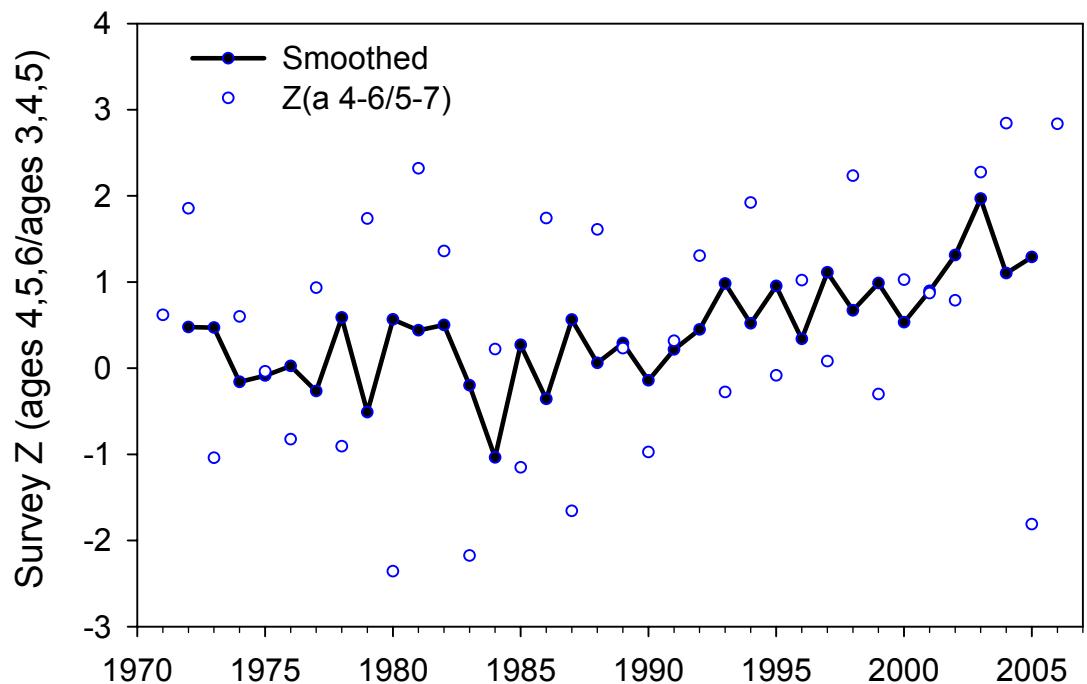

Fig. 33. Smoothed (running average of three year) estimates of total mortality from RV surveys, eastern component pollock. Annual estimates of total mortality (unsmoothed) are shown as open circles.
