## FOREWORD

This document is a product from a workshop that was not conducted under the Department of Fisheries Oceans (DFO) Science Advisory Process coordinated by the Canadian Science Advisory Secretariat (CSAS). However, it is being documented in the CSAS Research Document series as it presents some key scientific information related to the advisory process. It is one of a number of contributions first tabled at a DFO-SARCEP (Species at Risk Committee / Comité sur les espèces en péri) sponsored workshop in Moncton (February 2006) to begin the development of a 'Conservation Status Report' (CSR) for Atlantic salmon. When completed in 2007, the CSR could form the basis for a Committee on the Status of Endangered Wildlife in Canada (COSEWIC) status report, recovery potential assessment and recovery strategy, and most importantly, enable DFO to implement pre-emptive management measures prior to engagement in any listing process.

## AVANT-PROPOS

Le présent document est issu d'un atelier qui ne faisait pas partie du processus consultatif scientifique du ministère des Pêches et des Océans, coordonné par le Secrétariat canadien de consultation scientifique (SCCS). Cependant, il est intégré à la collection de documents de recherche du SCCS car il présente certains renseignements scientifiques clés, liés au processus consultatif. Il fait partie des nombreuses contributions présentées au départ lors d'un atelier parrainé par le MPO-SARCEP (Species at Risk Committee / Comité sur les espèces en péril) à Moncton (février 2006) en vue de commencer l'élaboration d'un rapport sur la situation de la conservation du saumon atlantique. Lorsqu'il sera terminé, en 2007, ce rapport pourrait servir de base à un rapport de situation du Comité sur la situation des espèces en péril au Canada (COSEPAC), à une évaluation du potentiel de rétablissement et à un programme de rétablissement mais, avant tout, il permettra au MPO de mettre en œuvre des mesures de gestion anticipées avant même de s'engager dans un processus d'inscription.

#### Abstract

Total one-sea-winter (1SW) $(1,159)$ and multi-sea-winter (MSW) $(350)$ returns destined for upriver of Mactaquac Dam on the Saint John River in 2005 were both the lowest on record since 1970. Wild origin fish comprised 74\% of 1SW and 73\% of MSW fish. Return rates for hatchery-released smolts were $0.38 \%$ (1SW) and $0.05 \%$ (2SW), an increase of $18 \%$ and a decrease of $54 \%$, respectively, from the values in 2004. Spawners numbered 1,060 1SW and 273 MSW salmon, $22 \%$ and $6 \%$ of the respective requirements. The egg deposition estimate ( $80 \%$ from wild fish) was $6 \%$ of the requirement, the lowest value on record. An additional 5.2 million eggs (or $18 \%$ of requirement) were potentially deposited from captive-reared spawners in 2005.

Counts at the Nashwaak River fence resulted in a return of 731 1SW and 162 MSW salmon. Return rates for wild smolts to 1SW and 2SW fish in 2005 were $5.13 \%$ and $1.58 \%$, a decrease of $20 \%$ and an increase of $25 \%$ from the previous year. Spawners represented $35 \%$ and $8 \%$ of the respective 1SW and MSW conservation requirements. An egg deposition of $16 \%$ of the requirement was similar to the previous year and slightly better than the five-year mean.

Counts of wild, hatchery and aquaculture origin salmon from fishways operated on the Magaguadavic and St. Croix rivers were 72 and 39 fish, respectively. Including the post smolts, ninety-six or $86 \%$ of the combined counts were deemed of aquaculture origin and denied access to both rivers. On the Magaguadavic River, five wild and four hatchery 1SW wild salmon were released upstream of the fishway which resulted in an estimated egg deposition of less than about $2 \%$ of the requirement. All hatchery salmon, two 1SW and four MSW fish, ascending the St. Croix River at Milltown were retained for broodstock purposes.

Total estimated returns and escapement of 1SW and MSW salmon to the Big Salmon River based on diver observations were 60 fish. The sixty fish represented less than $10 \%$ of the requirement and were three times greater than the returns the previous year.

Projected returns, based on the average returns of the previous five years, for populations originating upriver of Mactaquac Dam on the Saint John River in 2006 are 1,600 1SW (90\% C.I.; 820-2,360) and 680 MSW ( $90 \%$ C.I.; $160-1,250$ ) salmon. The probabilities of attaining the conservation requirement of 4,900 for both 1SW and MSW fish are near zero. Without a significant increase in both freshwater and marine survival, it is very unlikely that returns will be much greater than 2,000 fish in 2006.

Based on the five year average, 440 1SW (90\% C.I.; 120-780) and 170 MSW (90\% C.I.; 50-290) salmon are predicted to return to the Nashwaak River in 2006. Using the range (minimum and maximum) of smolt-to-1SW return rates observed since 1999 to the 2005 wild smolt estimate, the predicted 1SW returns to the Nashwaak in 2006 would be between 80 and 330 fish. Similarly, the predicted 2 SW salmon return in 2006, from the 2004 smolt class, ranges from 40 to 210 fish. The probability of attaining the conservation requirement of 2,040 for both 1 SW and MSW salmon is therefore near zero.

Wild and hatchery 1SW and MSW salmon returning to the Magaguadavic, St. Croix and Big Salmon rivers in 2006 are projected to be similar to the few fish that returned in 2005. There is a zero probability of attaining the conservation requirement in 2006.

## RÉSUMÉ

Le nombre total de saumons unibermarins (UBM) (1159) et pluribermarins (PBM) (350) remontant vers l'amont du barrage Mactaquac sur le fleuve Saint-Jean en 2005 ont été les plus faibles enregistrés depuis 1970. Les poissons sauvages constituaient $74 \%$ des poissons UBM et $73 \%$ des poissons PBM. Les taux de remonte des saumoneaux d'écloserie se sont établis à $0,38 \%$ (UBM) et à $0,05 \%(2 A M)$, pour une hausse de $18 \%$ et un déclin de $54 \%$ respectivement par rapport aux valeurs enregistrées en 2004. Le nombre de géniteurs a quant à lui totalisé 1060 individus pour les saumons UBM et à 273 individus du côté des saumons PBM, soit 22 et $6 \%$ des besoins respectifs. L'estimation de la ponte (80 \% provenant de poissons sauvages) représentait $6 \%$ des besoins, la valeur la plus faible enregistrée jusqu'à présent. Un nombre supplémentaire de 5,2 millions d'œufs (ou $18 \%$ des besoins) a pu être pondu par des géniteurs élevés en captivité en 2005.

Selon les dénombrements à la barrière de la rivière Nashwaak, une remonte de 731 saumons UBM et de 162 saumons PBM a eu lieu. Les taux de remontes des saumoneaux sauvages UBM et DBM en 2005 ont été de 5,13 et de $1,58 \%$, soit un déclin de $20 \%$ et une hausse de $25 \%$ respectivement par rapport à l'année précédente. Les géniteurs ont représenté 35 et $8 \%$ des besoins respectifs en saumons UBM et de PBM pour la conservation. La ponte, correspondant à $16 \%$ des besoins, a été similaire à celle de l'année précédente et légèrement en hausse par rapport à la moyenne quinquennale.

Les dénombrements de saumons sauvage, d'écloserie et d'origine aquicole effectués aux passes mogratoires des rivières Magaguadavic et Sainte-Croix se sont établis à 72 et 39 poissons respectivement. En incluant les postsaumoneaux, on estime que de 96 à $86 \%$ des dénombrements combinés correspondaient à des poissons d'origine aquicole, qui n'avaient pas accès aux deux rivières. Sur la rivière Magaguadavic, les cinq saumons sauvages et les quatre saumons d'écloserie UBM relâchés en amont de la passe migratoire auraient assuré une ponte estimée à moins de $2 \%$ des besoins. Tous les saumons d'écloserie, deux saumons UBM et quatre saumons PBM remontant la rivière St. Croix ont été prélevés à Milltown pour des fins de reproduction.

Le nombre total estimé de saumons UBM et PBM en remonte et en échappée vers la rivière Big Salmon, selon les observations de plongeurs, était de 60 individus. Ceux-ci représentaient moins de 10 $\%$ du besoin, mais leur nombre était trois fois supérieur à celui des remontes de l'année précédente.

D'après les remontes moyennes enregistrées au cours des cinq dernières années, les remontes prévues pour les populations originaires de l'amont du barrage Mactaquac sur le fleuve Saint-Jean en 2006 ont été de 1600 saumons UBM (IC de $90 \%$; 820-2360) et de 680 saumons PBM (IC de $90 \%$; 1601250). Les probabilités d'atteindre les besoins en matière de conservation de 4900 saumons UBM et PBM sont quasi nulles. Si l'on n'observe pas une amélioration significative de la survie en eau douce et en mer, il est très improbable que les remontes soient bien supérieures à 2000 poissons en 2006.

Si l'on se fonde sur la moyenne quinquennale, on prévoit que 440 saumons UBM (IC de $90 \%$; 120780) et 170 saumons PBM (IC de 90 \%; 50-290) remonteront la rivière Nashwaak en 2006. Si l'on compare la fourchette (minimum et maximum) du nombre de poissons UBM en remonte observés depuis 1999 et l'estimation du nombre de saumoneaux sauvages en 2005, les remontes de saumons UBM vers la rivière Nashwaak en 2006 devraient osciller entre 80 et 330 individus. De la même manière, les prévisions de 2006 concernant la remonte de saumons DBM issus de la classe de saumoneaux de 2004 varient de 40 à 210 individus. Ainsi, la probabilité de combler le besoin en matière de conservation de 2040 poissons UBM et PBM est quasi nulle.

On prévoit que les remontes de saumons sauvages et d'écloserie UBM et PBM vers les rivières Magaguadavic, Sainte-Croix et Big Salmon en 2006 seront similaires aux faibles remontes de 2005. Il est par conséquent improbable que l'on comble les besoins en matière de conservation en 2006.

## INTRODUCTION

This document assesses the status of Atlantic salmon (Salmo salar) populations for SFA 23. This comprises the outer Bay populations of the western part of SFA 23 including the Saint John River upriver of Mactaquac Dam, the Nashwaak River (a tributary to the Saint John River downriver of Mactaquac Dam), the Magaguadavic River and the St. Croix River. The Big Salmon River which is part of the "endangered" inner Bay of Fundy salmon populations is also included. The outer Bay salmon populations have declined significantly and have failed to attain egg conservation requirements for the last 20 years.

Data and analyses of Saint John River populations pertain primarily to populations originating upriver of Mactaquac Dam and the Nashwaak River. Data collections were made possible to a large extent because of collaborations with the Tobique Salmon Protective Association, Nashwaak Watershed Association, NB Power, as well as Kingsclear, Woodstock, Oromocto and Tobique First Nations. The data for the Magaguadavic River were provided by the Atlantic Salmon Federation and data for the St. Croix River were provided by the St. Croix International Waterway Commission. Data and analyses on the Big Salmon River were made possible from funds acquired from the Interdepartmental Recovery Fund and collaborations with Fort Folly First Nation, Fundy National Park, Atlantic Salmon Federation and New Brunswick Department of Natural Resources.

Projected returns for populations originating upriver of Mactaquac Dam on the Saint John River in 2005 were 1,630 1SW and 720 MSW salmon with probabilities of less than $1 \%$ of attaining the conservation requirement. Predicted returns to the Nashwaak River in 2005 were 400 1SW and 175 MSW salmon. The estimated smolt output from the Nashwaak River in 2004 along with the average smolt-to-1SW return rate, suggested that 1SW returns in 2005 would be 400 fish. 1SW and MSW returns to the Magaguadavic, St. Croix and Big Salmon rivers in 2005 were projected to be no greater than the few fish that returned in 2004 with a near-zero probability of attaining the conservation requirement.

Many of the outer Bay populations face a multitude of constraints. These include hydroelectric dams (with upriver passage facilities but most are devoid of safe downstream passage), artificial flow regimes, headponds, significant industrial and municipal effluents, run-off from intensive agricultural and forestry operations, and developing communities of invasive predators (i.e. muskellunge, smallmouth bass and rainbow trout). As well, juvenile and adult salmon escapes from the Fundy-Isle (NB) or Cobscook Bay (ME) aquaculture facilities are the most probable sources of aquaculture origin salmon identified at all primary counting facilities.

## SAINT JOHN RIVER UPRIVER OF MACTAQUAC DAM

Physical attributes, salmon production area (updated in Marshall et al. 1997), barriers to migration, fish collection and distribution systems, the role of fish culture operations (updated in Jones et al. 2004) and biology of the populations of the Saint John River drainage (Fig. 1), have been previously described in Marshall and Penney (1983). In 1983, the status of the salmon populations, since 1970, were estimated (Penney and Marshall 1984) and continued through to 2003 (Jones et al. 2004). The assessment documents for the 1998 and 1999 returns were less detailed than those done previous to 1998 (Marshall et al. 1999a, Marshall et al. 1999b, and Marshall et al. 2000). Stock status in 2000, 2001 and 2002 has been reported in the Atlantic Salmon Maritime Provinces Overviews (DFO 2001, DFO 2002, and DFO 2003). The approach in this assessment of populations in southwest New Brunswick is similar to that of the last detailed assessment completed in 2003 (Jones et al. 2004).

## Description of fisheries

The entire Saint John River has been closed to commercial fishing for Atlantic salmon since 1984, and the persistent failure of populations to achieve the conservation requirement has resulted in complete closures of the Aboriginal food and recreational fisheries since 1998. The recreational fishery has been closed since 1995 with the exception of a hook and release fishery that occurred from July 15 to August 12, 1997 (Marshall et al. 1998).

The Maritime Provinces' commercial salmon fishery has been closed since 1984 and, after several buy-backs of licences, has only four eligible but inactive licences remaining in the Saint John River area. The moratoria on commercial salmon fisheries since 1992 in insular Newfoundland and since 1998 in Labrador both continued in 2005.

## Returns destined for upriver of Mactaquac Dam

## Methods

The adjusted counts at Mactaquac Dam, estimates of removals in the main stem downriver of Mactaquac Dam and the assumed by-catch in May and early-June in downriver shad and gaspereau net fisheries are summed to give the total 1SW and MSW salmon returns (wild and hatchery origin) from upriver of Mactaquac Dam.

Counts at Mactaquac Dam consist of fish captured at the fish collection facilities at the Mactaquac Dam and at the smolt migration channel at the Mactaquac Biodiversity Facility. During 2005, the fish collection facilities at the dam and the migration channel at the biodiversity facility were operated from May 20 to October 25.

Returning salmon were sorted at the Mactaquac Biodiversity Facility sorting facility and were classified as being either of wild origin, hatchery origin or aquaculture escapes. Hatchery origin salmon that were released as 1 -year smolts at the smolt migration channel at the Mactaquac Biodiversity Facility or as juveniles (essentially fall parr) released upriver of Mactaquac, were principally identified by the absence of an adipose fin. Fish with an adipose fin but with some fin erosion were classified as hatchery origin if interpretation of scale patterns confirmed they were not an aquaculture escape. Suspected aquaculture escapes were identified by considerable erosion and partial regeneration of fin rays on all fins including the upper and/or lower lobes of the caudal fin, the presence of an adipose fin and the interpretation of scale samples. All other fish were classified as wild origin including returns from hatchery origin unfed and feeding fry that were more likely to have unclipped, un-eroded fins, and are indistinguishable from wild origin fish.

Marshall and Jones (1996) described the difficulty in distinguishing between adult returns from natural versus artificial recruitment because of the increasing numbers of unmarked hatchery distributions in the early and mid 1990's. Since 1998, the majority of the fall fingerling parr and spring smolts released upriver of Mactaquac Dam have had the adipose fin removed (Appendix i, Appendix ii, Fig. 2a, Fig. 2b). Scale samples are taken from approximately every second hatchery and wild fish (exceptions include the complete sampling of all broodstock). The proportion of wild and hatchery origin in the count was adjusted based on interpretation of these scales. The procedures used to adjust counts in 2005 are identical to those used since 1995 and described in Marshall and Jones (1996). The adjusted counts at Mactaquac Dam were used to estimate the returns and return rates for hatchery fish released as age- 1 smolts and some age0+ parr.

As in previous years, salmon by-catch in the lower river and in the Saint John Harbour was monitored by DFO fishery officers. Consistent with previous assessments, the assumed
catch rates were $1 \%$ of the 1 SW and $2.5 \%$ of the MSW river returns. Catches of salmon destined for upriver of Mactaquac Dam and caught downriver were assumed to consist of hatchery and wild origin salmon in the same proportions as the adjusted counts at Mactaquac.

## Results

Unadjusted counts of salmon at Mactaquac in 2005 totalled 1,126 1SW and 363 MSW salmon (Tables 1 and 2). Twenty-one (5.8\%) of the 363 MSW salmon counted at Mactaquac were reassigned to 1SW category on the basis of scale interpretation (Table 1). Interpretation of scales shifted the hatchery component among 1SW fish from $23.5 \%$ (Table 1) to $25.5 \%$ and among MSW fish from $25.9 \%$ to $27.5 \%$. The adjusted counts proportioned by age composition among hatchery and wild components since 1992 are tabled in Appendix iii. There were no aquaculture escapes identified in 2005.

There were no reports from DFO fisheries officers of illegal fishing in the main stem downriver of Mactaquac Dam in 2005. An estimated 12 1SW and 8 MSW salmon were ascribed to by-catch in the shad and gaspereau nets in the lower river and Saint John Harbour area (Table 1).

Adjusted wild origin and hatchery origin returns in 2005 were 1,159 1SW and 350 MSW fish (Table 1; Fig. 3). Both 1SW and MSW returns were the lowest in a 36 -year time series (Table 3). Adjusted returns of wild origin 1SW salmon were similar to those of 2004, and the previous five and ten year means, but was the seventh lowest annual estimate since 1970 (Table 3). Adjusted returns of wild origin MSW salmon were the third lowest in 36 years and were well below the five and ten year mean estimates (Table 3). The return rate to Mactaquac Dam of 1SW fish released as 1-year smolts was $0.38 \%$ - a slight improvement from the previous two years (Table 4a; Fig. 4). The return rate of 1-year smolts to Mactaquac Dam as virgin 2SW salmon (Table 4b; Fig. 4) was $0.05 \%$ - second lowest on record and about half that of the previous year.

## Removals of fish destined for upriver of Mactaquac Dam

## Methods

Removals from the potential spawning escapement destined for the traditional production areas upriver of Mactaquac include: 1) the estimate of 1SW and MSW salmon ascribed to by-catch in the estuary, 2) salmon passed or trucked upriver of Tinker Dam on the Aroostook River (Fig. 1), 3) salmon retained at Mactaquac as broodstock, and 4) salmon estimated to have been lost to poaching/disease, or handling operations at Mactaquac.

Losses to poaching and disease include those estimated to have been taken in the net fishery on the Tobique River, and known mortalities from fishways (Beechwood, Tobique and/or Tinker Dam) or the Tobique Half Mile Barrier. If detailed information was not available for the losses, they were apportioned to hatchery/wild components on the basis of known or estimated stock composition of fish released upriver of Mactaquac.

## Results

Reports from area fisheries officers indicated that there was illegal fishing activity near Tobique Narrows Dam in 2005 but the number of fish harvested was unknown. A fishing mortality estimate, derived from a fishway efficiency study (Jones et al. 2004) was applied to the number of fish passed upriver of Beechwood Dam and ascribed 60 fish in this illegal fishery. Unlike previous years, there were no adult salmon from Mactaquac transported to the Aroostook River upriver of Tinker Dam, although there were six 1SW and two MSW fish counted at the Tinker Dam fishway (Table 5). The area upriver of Tinker Dam was excluded from the "upriver of Mactaquac" conservation requirement (Marshall et al. 1997).

Total river removals from all sources were estimated at 99 1SW and 77 MSW fish (Table 5) of which 12 (10 males and two females) 1SW and 36 (twelve males and 24 females) MSW salmon were held at Mactaquac for broodstock. These early-run broodstock yielded about 161,000 eggs.

## Conservation Requirements

The conservation requirement is based on an accessible salmon-producing rearing area of $13,472,200 \mathrm{~m}^{2}>0.12 \%$ and $<15.0 \%$ gradient (Amiro 1993) upriver of Mactaquac Dam. This excludes the Aroostock River, headponds, and 21 million $\mathrm{m}^{2}$ of river with gradient $<0.12 \%$ (Marshall et al. 1997). Based on an assumed requirement of $2.4 \mathrm{eggs} / \mathrm{m}^{2}$ (Elson 1975), the conservation requirement is $32,330,000$ eggs. The numbers of spawners necessary to obtain the conservation requirement are estimated at $4,900 \mathrm{MSW}$ and $4,9001 \mathrm{SW}$ salmon (Marshall et al. 1997). Similar to previous years, egg deposition and spawners in 2005 were estimated on the basis of length, external sexing and interpretation of age from scales collected from fish captured at the Mactaquac Dam fishway (Jones et al. 2004).

## Escapement

## Sea-Run

Collation of the total sea-run (excluding captive-reared spawners) returns (Table 1) and total removals (Table 5) of wild and hatchery fish indicates that escapement was 273 MSW salmon and 1,060 1SW salmon (Table 6).

Differences in biological characteristics from 2004 included a decreased proportion of females among hatchery 1 SW salmon ( -0.02 ) and an increase in mean length $(+1.8 \mathrm{~cm})$. The proportion of females among wild and hatchery MSW fish increased by 0.08 and 0.12 , respectively, from 2004 (Table 7a). A decrease in mean length of wild ( -1.8 cm ) and hatchery ( 1.6 cm ) female MSW spawners was observed between 2004 and 2005. Proportion female and mean length of wild 1SW females in 2005 decreased from 2004 and the previous five year mean. Mean lengths, length-fecundity relationship, and estimated escapement indicate that the total potential deposition was 1.92 million eggs ( 0.142 eggs per $\mathrm{m}^{2}$ ) or $6 \%$ of the requirement. This is half the value estimated for wild female spawners in 2003 and 2004 (Fig. 5a). Estimated eggs from wild and hatchery 1SW fish comprised 17\% of the total deposition. Estimated eggs from hatchery origin 1SW and MSW salmon potentially contributed to $20 \%$ of the total deposition (Table 7a).

## Captive-Reared

Adult releases from the captive-reared broodstock program were distributed to sites in the Tobique River and just downriver of the confluence with the main Saint John River near Perth-Andover in 2003, 2004 and 2005. In 2004, to assess spawning of the captive-reared fish, an experiment similar to the Pokiok study in 2003 was conducted (Jones et al. 2004). Fifteen males and 15 females were released to a 5 km stretch of river on the Odell tributary
of the Tobique River. This section of river was not accessible to sea-run spawners because of an impassible falls. The captive-reared spawners were confined to the 5 km stretch of river by a counting fence (downstream) and another impassible falls further upstream. A redd survey was conducted and spawning activity was observed from the captive-reared releases. Further evidence of successful spawning was the presence of age-0+ or fry captured the following year by electrofishing.

To estimate the total egg contribution from the captive-reared releases in each year, a length-fecundity relationship was developed from 29 female, two-year captive-reared salmon that were retained at the Mactaquac Biodiversity Facility for the regular broodstock (compensation) program in 2005 (Fig. 5b). Using the mean length for each age category and the developed length-fecundity relationship (eggs $=337.93 \mathrm{e}^{0.0436 x \text { fork length }}$ ), the sexually mature females potentially produced another 5,206,000 eggs or an additional $16 \%$ of the conservation target in 2005 (Table 7b).

## In-river Ecological considerations

Discharges at Mactaquac Dam from May to the end of June (2005) fluctuated above the mean value from 1995 to 2004, with high discharges in early May (Fig. 6). Plots of weekly 1SW salmon counts from the fish collection facilities at the Mactaquac Dam and from the smolt migration channel at the Mactaquac Biodiversity Facility indicate that the majority of 1SW salmon in 2005 were captured about one week earlier than the previous 10-year mean (Fig. 6). Higher than normal (1995-2004 mean) weekly catches were observed for wild 1SW salmon during a two week period in late September and early October and fluctuated around the 10 year mean for hatchery 1SW salmon. The majority of the MSW returns entered the fishway during warm water conditions in July when estimated mean daily water temperatures for the Mactaquac fishway fluctuated around $20^{\circ} \mathrm{C}$ (Fig. 7). The 2005 mean daily water temperatures for Mactaquac fishway were estimated, because of water temperature recorder failure, using a relationship with an upriver site (just below Beechwood Dam). The peak arrival time for both the wild and hatchery MSW salmon returns in 2005 was similar to the previous 10-year mean (Fig. 7).

## Tobique River Parr Densities

## Methods

In 2004 and 2005, there was an increase in the number of electrofishing sites done with the intent to evaluate the efficacy of the captive-reared spawners released to the Tobique River. Subsequently a number of annually monitored sites in tributaries upriver of Mactaquac (Salmon (Vic. Co.), Shikatehawk, Meduxnekeag and Becaguimec rivers) were not completed. Assistance was provided by Tobique First Nation and Tobique Salmon Protection Association staff and included interns from the Federal Public Sector Youth Internship Program (FPSYIP). Densities (number of fish per $100 \mathrm{~m}^{2}$ of habitat) of age-1+ and older parr at these open sites were either derived using 1) mark-recapture techniques using the adjusted Petersen method (Ricker 1975) or 2) a mean probability of capture derived in Jones et al. (2004). Numbers of parr by age were determined from stratified sampling of large parr in 0.5 cm length intervals. Generally one parr was scale sampled for each interval. For the mark-recapture sites, the number of age-0+ parr or fry for the site was determined by applying the capture efficiency for age-1+ and older parr to the number of fry captured during the marking pass.

Similar to 2003, a mean probability of capture was applied to sites done in 2004 and 2005 in which zero parr were marked or recaptured or if only the marking pass was completed (Jones et al. 2004).

To evaluate the status of juvenile salmon upriver of Mactaquac Dam, densities of fry and parr were analyzed using the mean of 20 sites done on the Tobique River periodically since 1979. In 2004 and 2005, 16 of the 20 historical sites were completed. An additional 42 sites were completed in both years in an attempt to evaluate the spawning success of the captivereared releases.

With the exception of the 2004 (Table 8a) and 2005 (Table 8b) analyses, the densities presented are for wild (or adipose fin present) parr only. For the most part, prior to 1998 all fall fingerling parr and unfed fry were released unmarked (Fig. 2a and 2b) and suspected hatchery origin parr captured during electrofishing surveys were determined by observations of fin erosion or condition made by field staff. Since 1998, most of the fall fingerling parr released have been adipose clipped (with exception of 2004) and very few unfed fry (with exception of 2000) were released (Fig. 2a and 2b), making identification of wild parr more precise.

## Results

Analysis of the historical mark-recapture data (1996-2003) using the empirical Bayes method determined that the mean probability of capture was $34.7 \%$ (Jones et al. 2004). This mean probability of capture was used for 11 of the 16 sites done and for 37 of the 42 other sites electrofished on the Tobique River in 2004 (Table 8a). In 2005, the mean probability of capture was used on 36 of the 42 sites completed including 9 of the 16 index sites (Table 8b).

The mean density of wild fry (age-0+) at 16 sites on the Tobique River in 2004 and 2005 was 7.8 and 5.3 per $100 \mathrm{~m}^{2}$, respectively. Both values were an improvement from the density of 0.5 observed in 2003 (Fig. 8). With the exception of 1995, mean densities at the index sites have been below the "Elson norm" of 29 fry per $100 \mathrm{~m}^{2}$ (Elson 1967). No wild fry were captured at 10 (17\%) and 21 (36\%) of the 58 electrofishing sites completed in 2004 and 2005, respectively (Table 8a, Table 8b).

Mean density of age-1+ and older wild parr at the 16 index sites was 5.4 parr per $100 \mathrm{~m}^{2}$ in 2005. These values are well below Elson's (1967) "normal index" of 38 small and large parr per $100 \mathrm{~m}^{2}$ (Fig. 8). This value is above the mean density (2.6) observed in 2004, and reflects the improved mean fry density recorded in 2004 (Table 8a). Despite the low densities, parr appear to be well distributed throughout the watershed as only 10 sites in 2004 and 6 sites in 2005 sites were devoid of wild parr (Tables 8a, Table 8b).

## Tobique and Beechwood Smolt Investigations

In collaboration with the Tobique Salmon Protective Association, NB Wildlife Trust and Atlantic Salmon Federation spring smolt investigations upriver of Mactaquac Dam have been conducted since 2000. Several sampling techniques and assessment methods are used. The objectives are: 1) to estimate the numbers of wild and hatchery smolts emigrating from the Tobique River, 2) to estimate the proportion of the total smolt output emigrating as spring smolts in conjunction with fall pre-smolt assessment activities, 3) to obtain data on the spring migration patterns of Tobique River smolts and 4) to collect juvenile salmon for the captive-reared program at the Mactaquac Biodiversity Facility.

## Methods

In 2004, two rotary screw traps were installed in the main stem of the Tobique River just downriver of the confluence of Three Brooks tributary (Fig. 9) from April 26 until June 9. One rotary screw trap was constructed by E.G. Solutions ( 1.52 meters in diameter) and the second by Key Mill Construction Ltd. of Ladysmith, BC (1.82 meters in diameter) as described in detail in Chaput and Jones (2004). The wheels were continuously operated and checked once daily in the morning except on weekends when it was checked on either

Saturday or Sunday. All smolts were identified for origin (wild - adipose present or hatchery - adipose clipped or fin erosion), measured for fork length, marked with numbered streamer tags and scale sampled for later age determination. In 2004, to estimate the efficiency of the wheels, the majority of the captured smolts were released just downriver of the confluence of Burntland Brook (near Diamond Island); approximately 15 km upriver of the smolt wheels (Fig. 9). These smolts will be further referred to as "recycled" releases.

In 2005, one rotary screw trap (mark + release) was installed at the Plaster Rock site on May 7 and the other at the Three Brooks site (recapture + collection for captive-reared program) on May 9. Both were operational until June 9. In addition to the marked and released smolts captured at Plaster Rock, age-1 hatchery smolts from Mactaquac Biodiversity Facility were released upriver of the smolt wheels on three separate occasions to estimate the capture efficiency of the wheels (Jones et al. 2004).

In both years, hourly water temperature readings were recorded using a Vemco ${ }^{\odot} 1$ minilog installed in the main stem of the Tobique River at the Arthurette Bridge (Fig. 9). Environment Canada collected discharge data at a gauging station located in Riley Brook (Fig. 9). Discharge is affected by NB Power water storage facilities on four tributaries upriver of the Riley Brook gauging station.

Also in 2004 and 2005, the intake gatewells at the Beechwood Power Generating Station were sampled periodically for emigrating smolts during the spring migration period. A square nylon mesh net was used to capture smolts in the intake gatewells. Generally the net was left fishing for approximately 15 minutes in selected gatewells (Jones et al. 2004). All captured smolts were identified for origin (hatchery origin fish were adipose clipped or had some fin erosion), measured for fork length and weight, and approximately $20 \%$ of the smolts were scale sampled for later age determination. With the exception of a few mortalities the majority of smolts were released downriver of Beechwood Dam and the remainders were transported to the Mactaquac Biodiversity Facility for the captive-reared program.

## Results

2004
The two Tobique River smolt wheels captured a total of 291 wild and 49 hatchery smolts in April and May (excludes recaptured smolts; Table 9). Only six of the 340 smolts were captured in June (Fig. 10). The largest wild smolt catches occurred on May 4 and 5, approximately two weeks earlier than the peak in 2003. Increases in both mean daily water temperature (Fig. 10) and discharge (Fig. 11) in the main stem of the Tobique River likely contributed to the peak catches during this time period. Seventy-eight age-1 parr were also captured during the sampling period.

Numerical streamer tags were applied to 275 wild and hatchery smolts prior to release upriver of the smolt wheels near Burntland Brook. The estimated capture efficiency of the two wheels in 2004, based on the recapture of 17 of the recycled smolts, was $6.2 \%$. Mark-recapture data were incorporated into a Bayesian estimate procedure described by Gazey and Staley (1986) to determine the most probable estimate (the mode) of population size and a binomial distribution was assumed for random sampling error. The smolt run upriver of Three Brooks was estimated at 5,500 ( 2.5 and 97.5 percentiles; $3,785-9,875$ ) (Fig. 12), or 4,710 wild and 790 hatchery smolts, a $41 \%$ increase from the 2003 spring estimate. The hatchery smolt originated from fall parr releases. Since run size estimates were not calculated during the fall of 2003 the proportion of the total wild Tobique River smolt output represented by the 2004 spring smolt estimate is unknown.

[^1]Sampling at the Beechwood Dam intake gatewells occurred on June 16 and 18, 2004. A total of 234 smolts, including six smolts with streamer tags originally tagged and released in the Tobique River, were captured (Table 9, Fig. 10). As in the previous three years, greater than $85 \%$ were of wild origin. The six streamer tagged smolts were recaptured on average 30 days ( $\min =26$ days; $\max =33$ days) after being released upriver near Burntland Brook. The average recap time observed in 2004 was 20 days greater than the mean recap time in 2003 (Jones et al. 2004). These six recaptured smolts represented 2.2\% of the streamer tagged smolts available for recapture.

## 2005

A total of 88 and 64 unmarked smolts were captured during the five weeks of operation at Three Brooks and Plaster Rock, respectively (Table 9). Only five smolts were captured during the last week of operation. In general, catches in both smolt wheels were extremely low (<20 fish/day combined) making it difficult to relate catches with environmental factors in 2005 (Fig. 10, 11).

Only 62 smolts were tagged with numerical streamer tags and released from the Plaster Rock smolt wheel. One of the tagged smolts was recaptured in the smolt wheel at Three Brooks, resulting in an overall efficiency of $1.6 \%$. The smolt run was not estimated using this data because of the small sample sizes.

A total of 1,400 age-1 hatchery smolts were released near Burntland Brook at the same location as the recycled smolts in 2004. Fifteen (1.07\%) age-1 hatchery smolts from Mactaquac Biodiversity Facility were recaptured at Three Brooks and usually one-day after being released. It has been documented on the Tobique, Nashwaak and Big Salmon rivers, that using hatchery smolts released in the spring to estimate smolt wheel efficiencies can potentially overestimate the wild smolt run (Fig. 13). To account for the bias, an adjustment factor [0.5804 (calculations summarized below)] of the mean recapture rates of recycled wild versus spring released hatchery smolts was used to calculate the preferred spring smolt run estimate of 4,750 (2.5 and 97.5 percentiles; 3,640-7,120) (Fig. 12) or 3,400 wild and 1,350 hatchery smolts.

| Tobique River data only (from Jones et al. 2004) | recapture rates |  |
| :---: | :---: | :---: |
|  | hatchery | recycled |
| 2002 | 0.0412 | 0.0521 |
| 2003 | 0.0142 | 0.0432 |
| mean | 0.0277 | 0.0476 |
| adjustment factor (hatchery mean | $0.5804$ <br> recycled m |  |
| Recaps at Three Brooks |  | 15 |
| Adjusted number of Recaps |  | 26 |

Sampling at the Beechwood Dam intake gatewells also occurred with limited success in 2005. The sampling took place on June 6, 8 and 10 and a total of 16 wild and two hatchery smolts were captured (Table 9, Fig. 10). Only one streamer tagged smolt was recaptured four days after being tagged and released at Plaster Rock.

## Biological Characteristics

The analysis of scales collected from the wild smolts sampled at the smolt wheels on the Tobique River indicated that the majority of the smolts were age-2; $76 \%$ in 2004 and $62 \%$
in 2005. The mean length of all wild smolts combined has fluctuated annually between 14-15 cm since monitoring began in 2000 (Fig. 14). Wild smolts sampled on the Tobique River since 2000 were slightly smaller than those sampled on the Nashwaak River (Fig. 14). The highest proportion of the hatchery (released as fall parr) smolts sampled in 2004 (61\%) and 2005 (62\%) were age-1.

## Outlook

Projected returns, based on the average returns of the previous five years, for populations originating upriver of Mactaquac Dam on the Saint John River in 2006 are 1,600 1SW ( $90 \%$ C.I.; $820-2,360$ ) and 680 MSW ( $90 \%$ C.I.; $160-1,250$ ) salmon. The probabilities of attaining the conservation requirement of 4,900 for both 1SW and MSW salmon are near zero for both forecasts. Based on escapement of $20 \%$ and $6 \%$ of conservation in 2001 and 2002 respectively, and Tobique smolt production in 2005, wild 1SW salmon returns for 2006 will only increase if marine survival improves from recent years. Hatchery smolt releases in 2005 were $48 \%$ higher than 2004 so there could be a slight improvement in the number of hatchery 1SW salmon returns for 2006. A 67\% decrease in the number of hatchery smolts released in 2004 from 2003 suggests fewer hatchery 2SW returns in 2006.

## Management Considerations

For the Saint John River populations upriver of Mactaquac Dam, egg depositions have been less than $50 \%$ of requirement for 11 of the last 12 years. There is a near zero probability that MSW and 1SW returns will be adequate to meet the conservation requirement in 2006.

In an effort to maintain existing genetic integrity for potential recovery of the upriver populations and to reduce the number of wild sea-run removals for broodstock, a captive-reared broodstock program was initiated in 2001 at Mactaquac Biodiversity Facility (Jones et al. 2004). The first adult releases from this program occurred in 2003. There were significant potential contributions to egg depositions in 2004 and 2005 with the release of approximately 1,000 of these large salmon per year (Table 7b). The first adult (1SW salmon) returns from the 2004 releases are not expected until 2008.

## NASHWAAK RIVER

With a drainage area of about $1,700 \mathrm{~km}^{2}$, the Nashwaak River flows approximately 110 km in an easterly and southerly direction from Nashwaak Lake on the New Brunswick York/Carleton County line to its confluence with the Saint John River in Fredericton North (Figs. 1 and 15). It is the largest single salmon-producing tributary of the Saint John River downriver of Mactaquac Dam. The salmon production area of the Nashwaak River has been estimated from orthophoto measurements (Amiro 1993) at 5.69 million $\mathrm{m}^{2}$ (gradient $>0.12 \%$ ) or $28.5 \%$ of the total salmon production area downriver of Mactaquac Dam (Marshall et al. 1997). A salmon counting fence 23 km upriver from the confluence with the Saint John River (Fig. 15) was operated by DFO in 1972, 1973 and 1975 (Francis and Gallop 1979), and by DFO in cooperation with Aboriginal peoples from 1993-2005. In 2005, the fence was jointly operated by Kingsclear and Oromocto First Nations.

## Returns

## Methods

From June 9 until October 7, 2005, all fish captured at the counting fence were counted, measured for fork length, classified as hatchery or wild on the basis of fin deformities and/or
presence of adipose fin, and marked with a hole punch of the caudal (hatchery fish) or adipose (wild fish) fin. All adipose clipped salmon (hatchery fish) and wild salmon (>= 60 cm ) were scale sampled along with every second wild fish ( $<60 \mathrm{~cm}$ ) to determine the age composition of the adult returns. Exceptions were made to the sampling routine when water temperatures at the fence exceeded $22^{\circ} \mathrm{C}$. During these periods trap checks were made and fish were classified as 1SW or MSW salmon based on size, but no additional sampling occurred. No unmarked 1SW or MSW salmon were released upriver in 2005. Holding pools upriver of the fence were seined in early October so that mark-recapture procedures (Gazey and Staley, 1986) could be used to estimate the number of fish that may have bypassed the fence either before installation or when the fence could not operate properly due to high water.

## Results

Unadjusted counts at the Nashwaak River counting fence in 2005 were 427 1SW and 95 MSW salmon. The start date was similar to previous years but the finish date was earlier than normal because of extremely high water levels that topped the fence - the fifth occasion in 2005 (Table 11).

After scale analysis, 1SW and MSW salmon components were slightly revised to 425 1SW and 97 MSW salmon (Table 2). The final hatchery counts were twenty 1SW and two MSW salmon and represented less than $5 \%$ of the total 1SW and MSW salmon counts. The fall high water events prevent any meaningful comparison of the run timing in 2005 to previous years but generally very few 1SW and MSW salmon were counted during the month of August and the first two or three weeks of September (Fig. 16). Scale samples revealed that sea-ages of the wild fish in 2005 were $81 \%$ 1SW fish, $17 \%$ virgin 2 SW fish and $2 \%$ previous spawners. The proportion of 1SW and 2SW salmon returns is similar to values observed in seven of the last eight years; the exception being 1997 and 2001 (Fig. 17). Since 2000, the sea age of Nashwaak River wild salmon returns has been very similar to those wild salmon returning to Mactaquac Dam (Fig. 17). Previous spawners from 1993-2002 averaged about $25 \%$ of the returning Nashwaak River MSW salmon, but since 2002 have only comprised about $9 \%$ of the MSW returns. Very few virgin 3SW salmon were observed in either population (Fig. 17).

Seining and diver observations in 6 pools (Fig. 15) upriver of the salmon counting fence on October 6, 2005 resulted in the capture or visual observation of 14 small and 2 large salmon. Nine salmon of the 16 were previously adipose punched (marked) at the counting fence.

To estimate the total returns through October 5, 2005, it was necessary to determine the number of salmon moving upriver prior to fence installation and during time periods (Table 11) when the fence was not fishing due to high water. Mark-recapture data were incorporated into a Bayesian estimate procedure and this analysis indicates a population of 852 fish ( 2.5 and 97.5 percentiles; 648-1,740); Fig. 18) or 701 1SW and 151 MSW salmon moved past the fence as of October 5, 2005. The sum of these estimates and adjusted fence counts after October 5 yielded a return estimate of 731 1SW ( 2.5 and 97.5 percentiles; $565-1,460$ ) and 162 MSW ( 2.5 and 97.5 percentiles; 125-329) salmon. The 1SW salmon estimate was the fifth highest while the MSW return estimate was the third lowest since 1993 (Table 12). Because the fence did not operate during the high water flows that occurred after October 7 (Fig. 16) additional fish may have been missed. More than adequate discharge prior to October 7 and few (2.2\%) wild returning adults to Mactaquac Dam after October 7 suggest a large portion of the run was accounted for. Similar events occurred in 2003, when multiple periods of high discharge caused the fence to be compromised before all the salmon returns could be accounted for (Fig. 16). It was indicated that estimates likely represented $95 \%$ of the total returns in that year (Jones et al. 2004).

Estimated wild returns in 2005 totalled 697 1SW and 159 MSW fish (Fig. 19). One-seawinter returns, up slightly from 2004, were the highest estimated since 1998, and similar to the 10 -year mean. Multi-sea-winter returns decreased $22 \%$ from 2004, and were only $58 \%$ of the 10-year mean, and the third lowest estimated total since 1993. The return rate of the 2004 wild smolt class as 1SW salmon in 2005 was $5.13 \%$ - the second highest return rate since wild smolt assessments were initiated in 1998 (Table 13). The return rate of the wild smolt class of 2003 as 2SW salmon in 2005 was $1.58 \%$ - the highest return rate observed since the 2SW returns in 2000 and more than $25 \%$ higher than the rate in 2004 (Table 13). Estimated hatchery returns in 2005 totalled 34 1SW and three MSW fish. One of these hatchery MSW salmon returns was later classified to be an aquaculture escape based on scale analysis.

As in previous years, no account has been made of salmon by-catch in the Saint John Harbour that may have been destined for the Nashwaak River.

## Removals

Between June 24 and July 4, 15 1SW salmon and six MSW salmon were removed from the fence trap and transported to Mactaquac Biodiversity Facility for restoration initiatives by the Nashwaak Watershed Association Inc. Two 1SW salmon mortalities were recovered on June 24 and August 14 on the upriver side of the fence and two additional 1SW and one MSW salmon were dead inside the trap in September and were likely casualties of high water. DFO fishery officers reported no illegal activities targeting salmon destined for or within the Nashwaak watershed. Therefore, no corrections were made for illegal removals.

## Conservation Requirements

Salmon production area upriver of the fence is estimated to be 5.35 million $\mathrm{m}^{2}$ and the conservation requirement is 12.8 million eggs (Marshall et al. 1997). The numbers of spawners necessary to obtain the conservation requirement are estimated at 2,040 MSW and 2,040 1SW salmon (Marshall et al. 1997). Egg deposition and spawners in 2005 were estimated on the basis of length, external sexing and interpretation of age from scales collected from fish passing through the fence.

## Escapement

Spawners upriver of the fence were estimated to be 712 1SW and 155 MSW salmon (Table 12). Sea-age, origin, female composition and mean length for spawners upriver of the fence are summarized below:

|  | SW salmon |  | MSW salmon |  |
| :--- | :---: | :---: | :---: | :---: |
|  | Wild | Hatchery | Wild | Hatchery |
|  | 678 | 34 | 152 | 3 |
| Proportion female | 0.433 | 0.350 | 0.862 | 0.500 |
| Mean length female $(\mathrm{cm})$ | 57.8 | 54.1 | 78.3 | 74.4 |

Numbers of 1SW and MSW spawners were $35 \%$ and $8 \%$ of the conservation requirements, respectively. The number of 1SW spawners has steadily increased since 2001 while MSW spawners decreased by $27 \%$ from the spawners in 2004. Egg deposition was estimated at about $2,007,500$ ( 0.38 eggs $\mathrm{m}^{-2}$ or $16 \%$ of the egg requirement), similar to 2004
(Table 12). One-sea-winter females contributed $52 \%$ of the total estimated egg deposition, compared to $28 \%$ and $41 \%$ in 2003 and 2004, respectively.

## Parr Densities

## Methods

Densities of juvenile salmon have been monitored annually at seven sites on the Nashwaak River since 1981 (Fig. 15). Densities prior to 1981 along with site characteristics and locations were reported by Francis (1980). Assistance was provided by Woodstock First Nation and interns from the Federal Public Sector Youth Internship Program (FPSYIP). Densities (number of fish per $100 \mathrm{~m}^{2}$ of habitat) of age-1+ and older parr at these open sites were either derived using 1) mark-recapture techniques using the adjusted Petersen method (Ricker 1975) or 2) a mean probability of capture derived in Jones et al. (2004). Numbers of parr by age were determined from stratified sampling of large parr in 0.5 cm length intervals. Generally one parr was scale sampled for each interval. For the mark-recapture sites, the number of age-0+ parr or fry for the site was determined by applying the capture efficiency for age- $1+$ and older parr to the number of fry captured during the marking pass.

Similar to 2003, a mean probability of capture was applied to sites done in 2004 and 2005 in which zero parr were marked or recaptured or if only the marking pass was completed (Jones et al. 2004).

In 2004 and 2005, in addition to the seven sites continuously done since 1981, another 19 sites were added to the Nashwaak River juvenile surveys (Table 14a and 14b) and as a result a number of electrofishing sites historically monitored on the Keswick, Kennebecasis and Hammond Rivers were not completed by DFO.

With the exception of the 2004 and 2005 analyses (Table 14a, 14b), the densities presented are for wild (or adipose fin present) parr only. For the most part, prior to 1998 all fall fingerling and unfed fry were released unmarked and suspected hatchery origin parr captured during electrofishing surveys were determined through observations made by field staff of fin erosion or condition (Appendix iv). Since 1996, most fall fingerlings released were adipose clipped and there were fewer unfed fry releases, thereby making the identification of wild parr easier and more accurate.

## Results

Analysis of the historical mark-recapture data (which included Nashwaak River data) using the empirical Bayes method determined that the mean probability of capture was $34.7 \%$ (Jones et al. 2004). This mean probability of capture was used for three of the seven sites (historical) done annually since 1981 and for eight of the 19 additional sites electrofished on the Nashwaak in 2005 (Table 14b).

Mean density of wild fry (age-0+ parr) at the seven historical sites in 2005 (one downriver and six upriver of the counting fence) was 5.8 fry per $100 \mathrm{~m}^{2}$ and ranged from 0.0 to 15.0 fry per $100 \mathrm{~m}^{2}$. This is slightly higher than the 2003 and 2004 mean densities (Fig. 20) and consistent with the higher egg depositions estimated in 2004 (Table 12). Since 1993, mean densities at the seven sites have been below the "Elson norm", fluctuating around 9.0 fry per $100 \mathrm{~m}^{2}$ (Fig. 20). Including data from the 19 additional sites raised the mean density to 7.7 fry per $100 \mathrm{~m}^{2}$ and ranged from 0.0 to 30.5 fry per $100 \mathrm{~m}^{2}$ in 2005.

Mean density of age-1+ and older wild parr at the seven historical sites was 5.1 fish per $100 \mathrm{~m}^{2}$ (ranged from 0.0 to 11.3 ) and improved slightly to 6.0 fish per $100 \mathrm{~m}^{2}$ (ranged from 0.0 to 24.5 ) when the 19 additional sites were included in the analysis. These values
improved slightly from 2004 and were similar to the densities observed in the last decade, but are well below Elson's (1967) "normal index" of 38 small and large parr per $100 \mathrm{~m}^{2}$ (Fig. 20).

## Smolt Assessment

A collaborative project between DFO and the Nashwaak Watershed Association Inc. (NWAI) to estimate the wild smolt production of the Nashwaak River has been ongoing since 1998. The smolt production estimates are valuable in examining recent declines in salmon populations for the following reasons: 1) they contribute to the development of current expectations for and limitations to salmon production on the Nashwaak River and probably other tributaries of the Saint John River downriver of Mactaquac Dam, 2) they provide a marine survival estimate examined through smolt-to-adult return rates where adult returns are derived from data collected at the Nashwaak River counting fence, and 3) they provide a basis for evaluating freshwater production which can be examined through parr-to-smolt and egg-to-smolt survival rates when estimates of juvenile densities of salmon and eggs deposition are available.

## Methods

A smolt wheel was installed and operated from April 20 until June 9, 2005 in the main stem of the Nashwaak River just downriver of Durham Bridge. As in previous years (Marshall et al. 1999b) the wheel was checked once daily except during the first and last weeks of operation when it was checked for six of the seven days (only once on weekends). All smolts were identified for origin (wild or hatchery), one in five wild unmarked smolts was measured for fork length, weighed, scale sampled and released 500 meters downriver of the wheel. In general, the remaining unmarked smolts were marked with numbered streamer tags and released upriver near the confluence of the Tay River (Fig. 15). Detailed sampling occurred on all hatchery smolts released as fall fingerlings.

Hourly water temperature readings were recorded using a minilog thermometer installed in the main stem of the Nashwaak River at the adult counting fence location (500 meters downriver of the smolt wheel). Environment Canada collected discharge data at a gauging station located near Durham Bridge.

## Results

A total of 292 untagged smolts ( 255 wild; 37 hatchery-fall fingerling) were captured during smolt wheel operations. The highest wild smolt catch occurred on May 14, a couple of days after the mean daily water temperatures had exceeded $10^{\circ} \mathrm{C}$ (Fig. 21). The cooler spring water temperatures appeared to delay the smolt migration in 2005 different than six of the previous seven years (exception being 2003) when at least $50 \%$ of the cumulative smolt catch had occurred by May 9 (Fig. 21). High discharge put the smolt wheel out of operation from April 29 until May 1, 2005 but unlike water temperatures, smolt movements do not appear to be related to discharge on the Nashwaak River (Fig. 22). Only four wild and one hatchery smolts were captured during the last two weeks of operation.

One-hundred and eighty-three wild smolts were tagged with numbered streamer tags and released upriver of the smolt wheel at the mouth of the Tay River (Fig. 15). Nine (4.9\%) of the recycled smolts were recaptured at the smolt wheel. This mark-recapture data generated a most probable Bayesian estimate of 5,200 wild smolts ( 2.5 and 97.5 percentiles; $3,200-12,600$ ) emigrating from the Nashwaak River in 2005 (Table 13; Fig. 23). The total number of wild smolts decreased $62 \%$ from 2004, was only $40 \%$ of the five-year mean, and was the lowest estimated total since smolt assessment commenced in 1998 (Table 13). Using the capture efficiency of $4.9 \%$ from the wild smolts, an additional 750 hatchery smolts that
had been released as fall fingerlings in 2002 and 2003 were estimated to have emigrated in 2005.

## Biological Characteristics

The average fork length of all the wild smolts sampled in 2005 was $15.4 \mathrm{~cm}(\mathrm{n}=63)$. This was the largest mean length value for the wild smolts since monitoring began in 1998 (Fig. 14). Ages of wild smolts were predominately age-2 (59\%) with a mean length of 14.7 cm . The remaining wild smolts were age-3 and averaged 16.7 cm . Mean fork length values for age-2 smolts, in 2004 and 2005 were similar to those observed from wild smolts sampled since 1998, but mean length values for the age-3 smolts were the largest observed (Fig. 14).

## Outlook

Predicted returns to the Nashwaak River in 2006 using the five year average are 440 1SW fish ( $90 \%$ C.I.; 120-780). There is a near zero probability that the 1SW requirement of 2,040 fish will be achieved. The forecast of MSW returns is 170 fish ( $90 \%$ C.I.; 50-290) and the probability that the conservation requirement of 2,040 MSW fish will be attained is also near zero. Appling the range (minimum and maximum) of smolt-to-1SW return rates observed since 1999 to the 2005 wild smolt estimate indicates the predicted 1SW returns to the Nashwaak in 2006 could be between 80 and 330 fish. This method has proven to be a more reliable forecast in comparison to the five year mean. The predicted 2SW salmon returns in 2006, from the 2004 smolt class, range from 40 to 210 fish using the observed smolt-to-2SW return rates. Despite slight improvements in the numbers of adult returns and subsequent spawners, particularly 1SW salmon, parr densities remain low and suggest that returns will not be adequate to achieve the egg conservation requirement for several years to come.

## Management Considerations

The Nashwaak River population attained only about $16 \%$ of the conservation requirement in 2005. Total egg depositions were less than $25 \%$ of the conservation requirement for the last seven years and have steadily declined, along with the corresponding smolt classes, since 1996. Prospects for attaining the conservation requirement in 2006 are near zero, based on low parr densities and smolt estimates. The prospects for increased returns for the next several years are extremely poor although smolt-to-adult return rates have improved in 2004 and 2005. Unlike 1SW fish returning to Mactaquac Dam which have a low ( $<10 \%$ ) component of female 1SW salmon, the Nashwaak River 1SW salmon averaged 37\% female from 2001 to 2005. These females have contributed an average of $36 \%$ of the total Nashwaak River egg depositions over those same five years.

## MAGAGUADAVIC RIVER

Originating in Magaguadavic Lake, the Magaguadavic River flows southeasterly for 97 km to the Passamaquoddy Bay, Bay of Fundy at St. George, N.B. (Fig. 24; Martin 1984). The 13.4 m -high dam and 3.7 megawatt hydroelectric station (with 4 Francis turbines) located at the head-of-tide was replaced with a new 15 megawatt hydroelectric station (with 2 Kaplan turbines) in 2004. Upstream passage is provided by a fishway. A new downstream bypass and assessment facility was constructed in the new hydroelectric station. Assessment of the anadromous fish resources is done using a trap in the third pool from the top of the fishway. In 2005, the fishway trap was monitored for salmon from late April until early December. Salmon count data and analyses were provided by Atlantic Salmon Federation². In 2005, similar to the previous year, no fish of aquaculture origin that were captured at the trap were released to the river. All salmon of suspected aquaculture origin were sacrificed for sampling of pathogens.

Wild returning salmon have been rapidly declining since 1992 and have averaged less than 15 fish per year since 1998. Aquaculture fish are escapes from aquaculture cages in the Fundy Isle area which, in 2005, produced approximately 35,000 tonnes of Atlantic salmon.

## Returns

Counts of 1SW salmon in the trap numbered five wild and four hatchery fish. There were no wild or hatchery MSW salmon counted in 2005. Aquaculture escapes ascending the fishway in 2005 numbered six postsmolts, 62 1SW and one MSW salmon. It is possible that some of the "wild" salmon counted may be the result of early life stage juvenile escapes from any of the three private hatcheries in the drainage. Counts made since 1992, when aquaculture escapes were identified, and those in 1983-1985 and 1988, when escapes were largely unnoticed, are in Table 2. Total counts of both wild 1SW and MSW salmon were the highest observed since 2001 and higher than the mean for the last five years (Fig. 25). Counts of suspected aquaculture escapes were the second highest in the past five years (Table 2).

## Removals

All aquaculture fish were sacrificed for disease testing. No fish tested positive for the ISA virus. No fish were removed for broodstock. There has been no commercial fishery since 1983, and the Aboriginal food fishery and the recreational fishery have been closed since 1998.

## Conservation Requirements

The conservation requirement of 1.35 million eggs is based on an estimated $563,000 \mathrm{~m}^{2}$ of juvenile rearing substrate (Anon 1978) and a deposition of 2.4 eggs per $100 \mathrm{~m}^{2}$ (Elson 1975). The numbers of spawners necessary to obtain the conservation requirement are estimated at 230 MSW and 140 1SW salmon (Marshall and Cameron 1995).

## Escapement

Nine 1SW salmon were released upriver of the fishway. Using the mean length-fecundity relationship for Saint John River salmon (eggs=430.19e ${ }^{0.03605 X t o r k}$ length; Marshall and Penney 1983) and the estimated number of females suggest a potential egg deposition of 7,500 eggs or

[^2]less than $2 \%$ of the requirement. Estimates of escapement and attainment of the conservation requirement have steadily declined since 1994 (Fig. 26).

## Outlook

Wild 1SW and MSW returns to the Magaguadavic River in 2006 are projected to be no greater than the returns in 2005. There is a near zero probability of attaining the conservation requirement in 2006. Progeny of the last "disease free" wild adult returns in 1998 were distributed to the Magaguadavic watershed in 2003 as unmarked age-0+ parr (Appendix $v$ ) and are expected to contribute to adult returns in 2006-2007. This undertaking is a result of the action plan by the Magaguadavic Recovery Committee. Preliminary results from electrofishing surveys in 2003 indicate that the release of the 56 mature ( $35 \%$ female) captive reared broodstock in 2002 is unlikely to make a significant increase in adult returns in 2006-2007.

## Management Considerations

The Magaguadavic River population has declined dramatically in the last decade. Returns of wild salmon to the Magaguadavic River in 2005 were near zero and outnumbered by aquaculture escapes. There is no chance that the conservation requirement will be achieved from natural production on these rivers in the immediate future. Actions have been initiated to address the pending extirpation of these salmon populations by Live Gene Banking the remnant wild stock at the Mactaquac Biodiversity Facility.

## ST. CROIX RIVER

The St. Croix River, a USA/Canada international river bordering the State of Maine and Province of New Brunswick, drains southeasterly into Passamaquoddy Bay in the Bay of Fundy. Approximately $1,619 \mathrm{~km}^{2}$ of the drainage basin is in New Brunswick and $2,616 \mathrm{~km}^{2}$ is in Maine (Fig. 27). Historically a significant producer of Atlantic salmon, this salmon population has succumbed to industrial development - initially cotton mills, then pulp mills, and now dams and headponds at three hydroelectric facilities. The main stem and East Branch ( 84 km ), the Chiputneticook lakes ( 66 km ) and Monument Brook ( 19 km ) determine 169 km of the international boundary (Anon 1988), the fluvial portions of which comprise the bulk of the potential rearing area for Atlantic salmon.

No natural returning adult salmon have been released upriver since 1997. Future returns are dependant on hatchery programs. Without a dramatic shift in sea survival, these conservation efforts are not expected to yield any significant number of naturalized salmon in the near future. Hatchery releases since 1981 are tabled in Appendix vi.

## Returns

Counts of salmon at the Milltown fishway by St. Croix International Waterway Commission ${ }^{3}$ near head-of-tide on the St. Croix River in 2005 numbered four MSW and two 1SW hatchery origin fish, three MSW and 33 1SW aquaculture escapes, and no wild fish (Table 2, Fig. 28). Aquaculture escapes were removed from the fishway trap, sacrificed for laboratory disease analysis and found to be negative for the ISA virus. All hatchery origin fish were live-tested for the ISA virus and also found to be negative. There have been no wild returning adult salmon to Milltown fishway since 2000 (Table 2).

[^3]
## Removals

All six returning hatchery salmon were removed from the fishway trap and retained on site for fish health assessment and then later transported to Mactaquac for broodstock purposes.

## Conservation Requirements

The conservation requirement of $7,389,000$ eggs is based on an area of 3.079 million $\mathrm{m}^{2}$ of juvenile production habitat (Anon 1988) and an average requirement of 2.4 eggs $100 \mathrm{~m}^{-2}$ (Elson 1975). Adult requirements have been calculated on the basis of MSW salmon having a male to female ratio of 1:1 and females producing an average of 7,200 eggs. Adult requirements therefore total 2,052 MSW salmon. A re-evaluation of adult requirements in 1993 acknowledged the potential contribution to egg deposition by 1SW females and suggested 1,710 MSW and 680 1SW fish could potentially produce the egg requirement (Marshall and Cameron 1995).

## Escapement

For the eighth consecutive year, no wild or hatchery returning 1SW or MSW salmon were released upriver of Milltown Dam to spawn naturally.

Eggs from the hatchery returns were estimated from the length-fecundity relationship (eggs=430.19e ${ }^{0.03605 X f o r k}$ length $)$ for salmon of the Saint John River (Marshall and Penney 1983). Since no male adult salmon were captured at the fishway, the six female salmon that were transported to the Mactaquac Biodiversity Facility were crossed with male adults from the Tobique River captive-reared program to provide an estimated 58,000 eggs.

## Outlook

Returns to the St. Croix River in 2006 are unlikely to differ greatly from the mean value of 17 hatchery returns from 2001 to 2005 . This is because all returning adults have been retained as broodstock since 1997 and the number of stocked juveniles from these collections has remained constant and low. Under any scenario for returns in 2006, there is no probability of attaining the conservation requirement.

## Management Considerations

The salmon population of the St. Croix River has declined dramatically in the last decade. There have been no wild salmon returns since 2000 and hatchery returns have been less than 30 fish per year since 1997. There is little to no chance that the conservation requirement will be met from natural or hatchery production on this river in the near future.

## BIG SALMON RIVER

Located in southern New Brunswick, the Big Salmon River ( $45^{\circ} 25^{\prime} 0^{\prime \prime} \mathrm{N}, 65^{\circ} 24^{\prime} 0^{\prime \prime} \mathrm{W}$; Fig. 29) flows 27 km 's from the outlet of Walton Lake to the Bay of Fundy. It has a drainage area of $332 \mathrm{~km}^{2}$ with an estimated $494,000 \mathrm{~m}^{2}$ of accessible salmonid rearing habitat (Jessop 1975, 1986). Further characterisation of the river can be found in Jessop (1975, 1986). The Big Salmon River is home to a number of freshwater and diadromous fish species including the endangered inner Bay of Fundy (iBoF) Atlantic salmon (COSEWIC 2001), and is presently one of the key index rivers used in the recovery strategy for this unique salmon population. As such, references made to hatchery salmon in this section are more properly defined as those that were derived from the Live Gene Bank (LGB) at the Mactaquac Biodiversity Facility. Historical
reviews of Atlantic salmon at all life stages in the Big Salmon River have previously been completed by Jessop $(1975,1986)$ and more recently by Gibson et al. $(2003 a, 2004)$.

## Returns

## Methods

All adult salmon information for the Big Salmon River in 2004 and 2005 was collected through periodic dive counts between July and October, and annual fall redd surveys conducted by New Brunswick Department of Natural resources ${ }^{4}$. The lower section of the Big Salmon River includes 14 pools over roughly 3.0 km from Miller Pool to Amateur Pool inclusive (Fig. 29, not all pools shown in lower stretch) and the annual redd surveys cover approximately $45 \%$ of the spawning habitat in the headwater area (Gibson et al. 2003a). When and where the numbers of adult salmon in a pool were sufficient, the pool was seined to catch fish and thereby collect biological information from as many salmon in the pool as possible. Information included; fork length, sex (visual distinction, when possible), scales to determine age, and tissue samples for genetic analysis. Population estimates were generated using a single census markrecapture value (0.57) and assuming a binomial distribution of errors (i.e. fish can be observed more than once). This value originated from the observation of four of seven marked fish during the Big Salmon River adult surveys in 2003 (Gibson et al. 2004). Egg deposition estimates were determined from a length-fecundity relationship established for Atlantic salmon in the Stewiacke River, Nova Scotia (Amiro and MacNeill 1986); an iBoF river and an index river in the recovery strategy that best represents salmon of the iBoF.

| Date | No. persons | Activitiy |
| :---: | :---: | :---: |
| 2004 |  |  |

| September 14-15 | 12 | - upper ${ }^{a}$ and lower sections swam/observed <br> - seined Walton Dam and Miller pools |
| October 20 | 10 | - upper, middle and lower sections swam/observed |
| 2005 |  |  |
| August 3 \& 5 | 7 | - upper ${ }^{a}$ and lower sections swam/observed <br> - seined Walton Dam pool |
| September 7 \& 8 | 5 | - upper and lower sections swam/observed <br> - seined Walton Dam and Mast Brow pools |
| September 14 | 9 | - seined Katt pool |

a - Mast Brow pool omitted from observation

## Results

Usually, counts from the latest in-season observations were used to determine the population estimate of returning adults to the Big Salmon River. In 2004, three separate diver counts were conducted. During the July to September surveys, the majority of salmon were seen in the lower section of the Big Salmon River, but in the final dive count no salmon were observed in the middle and lower sections while four small and five large salmon were observed in the upper section (Table 15). Appling the single census mark-recapture value (0.57) to the nine fish suggested 16 adult salmon returned to spawn in 2004 (Fig. 30). Only one large salmon (age 2.2) was caught and sampled on September $15^{\text {th }}$ (Table 16). A redd survey was conducted on November $10^{\text {th }}$ and revealed a total of 43 redds in 2004. In 2005, the dive counts and seine surveys were conducted on three occasions between August and September. On August 3,

[^4]twelve small and eight large salmon were observed in the upper and lower sections of the Big Salmon River and on the following survey (September 7) 23 small and 11 large salmon were observed (Table 15). Similar to 2004, only one hatchery salmon was observed in 2005 (Table 15). Using the single census mark-recapture rate from 2003 and the 34 fish observed on September 7, there was an estimated return of 60 adults to the Big Salmon River in 2005 - the largest estimated return since 2000 (Fig. 30). It should be noted however, that this is potentially a minimum estimate since high water conditions did not permit further observations or counts later in the season (i.e. October). The annual redd survey conducted on Nov $8^{\text {th }}$ observed 70 possible redds in the headwater region of the Big Salmon River. Samples were collected from 23 adult salmon (Table 16); all but four were small salmon, and the majority (12/19) were males (the four fish sampled in August could not be sexually differentiated) (Table 16).

## Conservation Requirements

Approximately 280 small salmon and 420 large salmon are required to achieve the conservation requirement of 2.2 million eggs established for the Big Salmon River by Marshall et al. (1992).

## Escapement

It was estimated that 16 and 60 salmon returned to the Big Salmon River in 2004 and 2005, respectively (Fig. 30). Only one of the salmon (age $=2.2$, fork length $=80.4 \mathrm{~cm}$ ) was sampled in 2004 and therefore did not permit a reasonable estimation of the percentage of the conservation requirement that was achieved. In 2005, 23 salmon were sampled and a ratio of 19 1SW to four MSW salmon based on age was determined (Table 16). This resulted in 17.9\% and $2.4 \%$ of the conservation requirement for the Big Salmon River (summarized below).

|  | 1SW salmon | MSW salmon |
| :--- | :---: | :---: |
| Conservation requirement | 280 | 420 |
| Estimate | 50 | 10 |
| Percent of requirement | $17.9 \%$ | $2.4 \%$ |

Additionally, sex was visually determined from 19 of the 23 salmon sampled and results suggested $29.4 \%$ ( $5 / 17$ ) of the 1 SW and all ( $2 / 2$ ) of the MSW salmon were females (Table 16). Based on the length-fecundity relationship (eggs $=431.3 \mathrm{e}^{0.0368 \cdot \text { fork length }) ~ f r o m ~ A m i r o ~ a n d ~}$ MacNeill (1986), egg deposition estimates in 2005 were 47,648 eggs for the 1SW and 45,460 eggs for the MSW estimated salmon returns. Combined, this represents $4.2 \%$ of the conservation requirement for the Big Salmon River in 2005. Potential egg contributions from 13 (2004) and 62 (2005) female captive-reared adults released to the Big Salmon River were not estimated in this report (Appendix vii).

## Parr Densities

## Methods

Juvenile salmon surveys were completed at seven closed sites (barrier nets) and 11 open sites (spot-checks and mark-recapture) in the Big Salmon River in 2004 and 2005 (Fig. 31). Previous summaries of juvenile densities for the Big Salmon River have been completed by Amiro and Longard (1995) and Gibson et al. (2003a, 2003b, 2004). Density estimates (juvenile salmon per $100 \mathrm{~m}^{2}$ ) were determined for:

- open sites (spot-checks only) using a previously established catchability coefficient of $42.8 \%$ (Gibson et al. 2004),
- open sites (mark-recapture) using the adjusted Petersen method (Ricker 1975), and
- closed sites (barrier nets) using Zippen's (1956) maximum likelihood technique.

All parr captured were identified to origin by the presence (wild) or absence (hatchery) of an adipose fin and later confirmed through scale and tissue analysis. Age- $0+$ fish were considered 'wild' since their adipose fin is not removed prior to release as unfed fry. Subsequent extrapolation of wild or hatchery origin can be done, if captured, in future electrofishing surveys. Corresponding age and origin ratios were applied to the overall density at each site. For all parr at open sites, fork length and weight were measured, scales were removed (except from age$0+$ ) and an upper portion of the caudal fin was removed for genetic analysis. At closed sites fork lengths were measured for all parr, scales were retained from a single parr in each 0.5 cm fork length interval, and tissue samples from wild and hatchery parr (except age-0+) were pooled separately by site.

## Results

In 2004 and 2005, the mean density (fish per $100 \mathrm{~m}^{2}$ ) for wild salmon was greatest for age-0+ parr ( 14.0 in 2004 and 15.9 in 2005), and decreased as parr grew older (Table 17). For hatchery salmon age-1+ densities were 3.4 (2004) and 1.9 (2005), and for age-2+ parr were 0.3 in 2004 and 0.1 in 2005 (Table 17). The large fluctuations associated with the age$0+$ wild densities in particular, are likely attributed to the location of sites in respect to unfed fry releases during a given year. Densities for all age classes were similar to those estimated since 2000 (Gibson et al. 2003b, 2004).

## Smolt Assessment

Atlantic salmon smolt monitoring and assessments in the Big Salmon River were conducted using a rotary screw fish trap with the help of Fort Folly First Nation in 2004 and 2005. All data with respect to Big Salmon River smolt activities from 2001-2005 is not reported here, but can be found in Flanagan et al. (2006).

## Outlook

Although the estimated number of adult returns to the Big Salmon River has increased slightly in 2005, it represents only $2.4 \%$ and $17.9 \%$ of the large and small salmon conservation requirement outlined by Marshall et al. (1992). In addition to current juvenile densities and smolt estimates, which are largely influenced by supplementation of unfed fry, fall fingerlings and spring smolts from the LGB, as well as the low marine survival, the inner Bay of Fundy population of Atlantic salmon in the Big Salmon River is likely to remain critically low.

## Management Considerations

Recent results from the various monitoring and assessment activities at all life stages in the Big Salmon River has resulted in a mild shift in the release strategy for iBoF Atlantic salmon in which more LGB progeny are being released as unfed fry and fall fingerling, while reducing the number of spring smolts released (Appendix vii). The continuation of these activities is necessary to maintain the current knowledge base, persistence and eventual recovery of this important population of salmon.

## ACKNOWLEDGEMENTS

The data and analyses were made possible only with the support of many co-workers, in particular field supervisors J. Mallery and C. Fitzherbert. Counts and detailed biological characteristic data of salmon captured at the Mactaquac Dam, essential to the assessment of this population, were provided by the staff at Mactaquac Biodiversity Facility, in particular D. MacDonald. Counts of salmon at the Tobique Narrows fishway were assisted by NB Power and Tobique Salmon Protective Association (TSPA). Counts of salmon at Beechwood Dam fishway were provided by NB Power and at Tinker Dam by WPS Canada Generation Inc. The Kingsclear and Oromocto First Nations operated the salmon counting fence on the Nashwaak River. Oromocto, Tobique, Woodstock First Nations, and the TSPA were active in the juvenile electrofishing surveys. L. Sochasky and D. McLean (St. Croix International Waterway Commission) provided counts and scales from salmon ascending the Milltown fishway. J. Carr, Atlantic Salmon Federation (ASF), provided counts and analyses for the Magaguadavic River. We thank the Nashwaak Watershed Association Inc. (NWA) (in particular P. Salonius) and the TSPA (in particular R. O'Donnell and C. McCluskey) for their participation and support of the Nashwaak and Tobique smolt projects and the ASF and the NB Salmon Council for use of the smolt wheels. Most of the monitoring projects benefited from having interns from the FPSYIP. The Big Salmon River data would not have been possible without the assistance received from staff at Fort Folly First Nation, Fundy National Park, Atlantic Salmon Federation, Woodstock First Nation, New Brunswick Department of Natural Resources and funding from the Interdepartmental Recovery Fund. Discharge data was provided by Environment Canada and NB Power. The authors also thank M. Bradford, D. MacDonald and L. Marshall for their helpful comments and suggestions on earlier versions of this document.

Table 16. Biological information collected from adult salmon in the Big Salmon River, New Brunswick. Age is shown as FW.SW.FS, where FW is the number of years in fresh water, prior to smoltification, SW is the number of years in saltwater since smoltification, FS is the sea age of first spawning, and where 'na' is indicated the age at that point could not be determined. "Adipose punch" is a hole punch in the adipose fin - the resulting tissue is retained for DNA analysis.

Fig. 1. Map of the Magaguadavic, St. Croix and Saint John River drainages including Tobique and Nashwaak rivers and other major tributaries, dams, and principal release sites for Atlantic salmon up river of Mactaquac Dam. Fish trapping locations on the Tobique and Nashwaak drainages are shown in Fig. 9 and Fig. 11. Note that the Mactaquac Fish Culture Station is now referred to as the Mactaquac Biodiversity Facility.

Fig. 2a. Number of juvenile salmon less than 52 weeks old (excludes age-1 smolts) released or distributed to tributaries up river of Mactaquac Dam, Saint John River, 1976-2005.

Fig. 2b. Number of juvenile salmon less than 52 weeks old (excludes age-1 smolts) released or distributed to the Tobique River, 1976-2005.

Saint John River at Mactaquac

Fig. 3. Estimated total adjusted returns of wild and hatchery 1SW and MSW salmon destined for Mactaquac Dam, Saint John River, 1970-2005.

Fig. 4. Return rates of hatchery reared smolts to virgin 1SW and virgin 2SW salmon destined for Mactaquac Dam, Saint John River, by smolt year, 1974 - 2004.

Fig. 5a. Estimated egg deposition up river of Mactaquac Dam, Saint John River, 1970-2005.

Relationship between Fork Length and Fecundity

Fig. 5b. Relationship between female fork length (cm) and fecundity of 29 captive-reared salmon at the Mactaquac Biodiversity Facility, 2005.

Fig. 6. Mean daily discharge ( $\mathrm{m}^{3} / \mathrm{sec}$ ) from 1995 to 2004 and mean weekly counts ( 1995 to 2004) of wild and hatchery 1SW salmon at Mactaquac Dam compared to 2005.

Fig. 7. Mean daily water temperatures ( ${ }^{\circ} \mathrm{C}$ ) from 1996-2004 and mean weekly counts (19952004) of wild and hatchery MSW salmon at Mactaquac Dam compared to 2005. The 2005 mean daily water temperature was estimated from an upriver site just below Beechwood Dam.

Fig. 8. Mean densities of age 0+ (fry) (upper panel) and age 1+ and older parr (lower panel) from electrofishing sites on the Tobique River in relation to the "Elson Norm" from 1978 to 2005.

Fig. 9. Map of Tobique River showing the location of the rotary screw traps (circles), release sites for smolts (squares) and adults (diamonds), the temperature recorder (star), the trapnet (star), the half mile fish protection barrier (circle) and river gauging station (star) sites.

Fig. 10. Daily wild and hatchery smolt catches at smolt wheel(s) and Beechwood Intake Gatewells, 2002 - 2005. The mean daily water temperature $\left({ }^{\circ} \mathrm{C}\right.$ ) at Arthurette (Tobique plots) and Beechwood tailrace (Beechwood plots) is shown. The smolt catches are combined for the two smolt wheel sites operated in 2005.

Fig. 11. Wild and hatchery smolt catches at smolt wheels on the Tobique River and at the intake gatewells at Beechwood Dam, 2002-2005. Mean daily discharge at Riley Brook (Tobique plots) and at Mactaquac (Beechwood plots) is shown. Mactaquac discharge is used as a proxy for Beechwood. The smolt catches are combined for the two smolt wheel sites operated in 2005.

Fig. 12. Probability density (dots) and cumulative probability (black line), estimated using mark-recapture techniques, for the number of wild and hatchery Atlantic salmon smolts emigrating from the Tobique River (Three Brooks), 2004-2005.

Fig. 13. Various rotary screw trap (or smolt wheel) capture efficiencies of wild, hatchery - fall fingerling (FF), hatchery -spring released (untagged and tagged) smolts from the Tobique, Nashwaak, and Big Salmon rivers (Big Salmon River data from Flanagan et al. 2006).

## Length of Wild Spring Smolts

Fig. 14. Mean fork length, by age, for wild smolts sampled during assessment projects on the Nashwaak (1998-2005) and Tobique (2000-2005) rivers.

Fig. 15. Map of Nashwaak River, indicating adult counting fence site (star), rotary screw trap site (square), smolt fence (star), seined pools (circles), and electrofishing sites (*).

Fig. 16. Average daily discharge ( $\mathrm{m}^{3} / \mathrm{sec}$ ) at Durham Bridge and adjusted fence counts of 1SW and MSW salmon, Nashwaak River, 2002-2005.

Fig. 17. The percentages of wild virgin 1SW, 2SW, 3SW and previous spawning (repeat spawning) Atlantic salmon in the total returns to the Nashwaak River and to Mactaquac, from 1993 to 2005.

Fig. 18. Probability density (dots) and cumulative probability (black line) for the number of 1SW and MSW salmon returning to the Nashwaak River up to October 6, 2005, based on markrecapture techniques.

1SW Salmon Returns to the Nashwaak River

Fig. 19. Estimated wild and hatchery 1SW and MSW salmon returns to the Nashwaak River, 1993 to 2005.

Fig. 20. Mean densities of age-0+ (fry) (upper panel) and age-1+ and older parr (lower panel) from electrofishing sites on the Nashwaak River in relation to the "Elson Norm" from 1981 to 2005.

Fig. 21. Daily mean water temperatures $\left({ }^{\circ} \mathrm{C}\right)$ and catches of wild smolts, Nashwaak River, 1998-2005.

Fig. 22. Daily mean water discharge ( $\mathrm{m}^{3} / \mathrm{sec}$ ) and catches of wild smolts, Nashwaak River, 1998-2005.

Fig. 23. Probability density (dots) and cumulative probability (black line), estimated using mark-recapture techniques, for the number for the number of wild Atlantic salmon smolts emigrating from the Nashwaak River, 2004 and 2005.

Fig. 24. Map of the Magaguadavic Watershed.

Fig. 25. The number of wild 1 SW and MSW salmon returns and aquaculture escapes entering the Magaguadavic River, 1983-85, 1988, 1992-2005. The 2005 wild returns includes four hatchery origin fish.

Fig. 26. Estimated egg depositions from wild 1SW and MSW salmon released up river of the fishway in the Magaguadavic River from 1992 to 2005. The 2005 estimated number includes eggs from both wild and hatchery origin fish.

Fig. 27. Map of St. Croix Watershed.

Fig. 28. The number of, wild and hatchery 1SW and MSW salmon returns and aquaculture escapes entering the St. Croix River from 1981 to 2005.

Fig. 29. Map of the Big Salmon River showing locations of pools (stars), area of redd surveys conducted by NBDNR (two shaded gray lines) and upper/middle/lower river stretches commonly observed during dive counts.

Fig. 30. Numbers of small and large salmon from dive counts and the yearly population estimate for the Big Salmon River, 2000 - 2005.

Fig. 31. Electrofishing sites on the Big Salmon River, 2004 - 2005.

Appendix $i$. Numbers of juvenile hatchery salmon distributed to sites up river of Mactaquac Dam (excluding distributions to the Aroostook River), 1976-2005. Fry are between zero to 14 weeks old, $0+$ parr are at least 14 weeks old but less than one year old and $1+$ parr are at least one year old but less than two years old.

Appendix iii. Adjusted counts, by age, of wild and hatchery 1SW and MSW salmon to Mactaquac Dam, 1992-2005. The smolt age distribution for the 1992-1994 returns was completed without considering the monthly sampling differences so these numbers are likely to change slightly and should be considered temporary.

[^0]:    * This series documents the scientific basis for the evaluation of fisheries resources in Canada. As such, it addresses the issues of the day in the time frames required and the documents it contains are not intended as definitive statements on the subjects addressed but rather as progress reports on ongoing investigations.
    * La présente série documente les bases scientifiques des évaluations des ressources halieutiques du Canada. Elle traite des problèmes courants selon les échéanciers dictés. Les documents qu'elle contient ne doivent pas être considérés comme des énoncés définitifs sur les sujets traités, mais plutôt comme des rapports d'étape sur les études en cours.

    Les documents de recherche sont publiés dans la langue officielle utilisée dans le manuscrit envoyé au Secrétariat.
